マグドウダム

MAGUDU DAM record of site survey

As of FWL-0.8m

EMBANKMENT	Location	Photo No.	Condition	Evaluation		Management: ZINWA	Proposed Measures
Upstream	D(1)		Disturbance of riprap, dam body exposure and erosion	B	Since there is no significant collapse or subsidence, it is judged that the embankment stability and water storage function is not affected. However, the exposure of dam body may accelerate the erosion of the embankment, so it is judged that measures are required in the long term.	To re-establish rip-rap.	
Downstream	D(2) D(3) D(4) D(5)		Gully erosion on the downstream surface. Erosion depth about 80cm, depression depth 1.8m, width 2.7m, etc. A surface water flow path (ditch) has been created in the downstream direction. Erosion is also observed on both sides of the stairway on the left bank.	B	As no seepage is observed even under high water level conditions, it is judged that there is no affect on the embankment stability and water storage function at present. However, the cross-section of the embankment may shrink in the future. In addition, since soil and sand are flowing into the valve house due to erosion, it is judged that measures are needed in the long term.	To prevent the recurrence of erosion and collapse, reshape the surface layer with embankment materials and install anti-erosion materials and riprap. Alternatively, a new bearing canal can be installed at the top, small step, and at the edge of the slope.	
Crest of dam	D(6)		Disturbance of riprap, dam body exposure and erosion.	B	Even under high water level conditions, there is no seepage on the downstream surface, so the embankment stability and water storage function is not affected. However, the exposure of the dam body may accelerate the erosion of the embankment, so it is judged that measures are required in the long term.	To re-establish rip-rap and trim trees. In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.	
Foot of slope	D(7) D(8) D(9) D(10)		There are collapses due to erosion (the height of the collapses are 1.7m and 1.2m at the largest). In the original riverbed area, trees are growing but there are no signs of wetness. In the downstream, a small stream is observed and connects to the connecting canal (on the flowbed, reddish brown and a film is also observed).	C	The volume of leakage is small even under high water level conditions, so it is judged that the water storage function is not affected. *The erosion at the edge of the embankment will be dealt with as part of rehabilitation of the embankment.	Not required: Continue regular monitoring.	
Right side abutment	D(11)		There is no disturbance in the abutment. The land is high mountain. There is farmland on the downstream side.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.	Not required: Continue regular monitoring.	
Left side abutment	D(12)		At the boundary of the spillway, no disturbance is observed.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.	Not required: Continue regular monitoring.	

MAGUDU DAM record of site survey

As of FWL-0.8m

Location	Photo No.	Condition	Evaluation	Proposed Measures
SPILLWAY				
Crest	S(1) S(2) S(3) S(4)	Surface concrete peeling at the top and downstream of the weir. (L7.5m/t5cm, h50cm/ t5cm)	B	Since the damage is slight, it does not affect the function at present. However, it is judged that measures are required in the long term, as the damage may expand due to long-term use.
Apron	S(5) S(6)	No significant damage is observed.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.
Retaining wall	S(7)	No significant damage is observed.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.
SPILLWAY CHANNEL				
All over the structure		No significant damage is observed.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.
CONNECTION CANAL				
Right bank side	C(1)~(4)(7)(8)	There is a large amount of erosion in two places around the upstream valve house approaching about 6 m to the embankment and 1.5 m to the valve house slope protection work.	A	Erosion can affect the stability of the embankment near future. Further erosion causes the slope protection collapse of the valve house and the influx of large deposits into the valve house, which causes problems in valve operation.
Left bank side	C(5)	There is a large erosion in the upstream part of the maintenance bridge on the left bank side of the downstream part.	B	Revetment is required before the distribution channel is affected. Since the deformation may spread in the long term, it is judged that countermeasures are required in the long term.
Canal bed	C(6)	The siphon protector is exposed on the riverbed.	A	In future, destroyed bedrocks may collaps the siphon protection, which causes a problem for water distribution.
INTAKE				
Inlet	I(1)	The flap valve cannot be opened and closed because there is no opening and closing device on the upstream side.	B	Problems occur when the downstream valve fails.
Outlet	I(2) ~(3)	The valve house cannot be drained. It is devised to prevent rainwater from flowing into the valve house due to embankment.	C	Install a new flap valve operation equipment. To keep continuous monitoring. Since there is no significant deformation, it is judged that no countermeasures are necessary.

MAGUDU DAM record of site survey

As of FWL-0.8m

Location		Photo No.	Condition	Evaluation	Proposed Measures	
MAIN CANAL						
Whole line	M(1)~(35)	There are cracks in the bottom slab throughout the channel.	C	Since it has the plain concrete structure and no water leakage is observed in the surrounding area, observation is required. It is repaired every year and is maintained by ZIMWA. Since there is no significant deformation, it is judged that no countermeasures are necessary.	To keep continuous monitoring.	
ON FARM Facilities						
Night storage	OF(1)~(6)	Sediment is occurring.	C	Sediment is processed every two years and is maintained. There is information that the capacity is insufficient because the field area of the original plan was expanded from 37ha to 52ha now. A pond has been created due to water leakage from Night storage, and this is being maintained to cultivate tilapia. Since there is no significant deformation, it is judged that no countermeasures are necessary.	To keep continuous monitoring.	
Night storage	OF(2)	The inlet gate has been broken.	B	The outlet valve cannot be maintained easily. It is not mandatory to install it. This is because when maintaining the outlet valve, the water level in the naigth storage should be lowered. Long-term measures are required to repair the downstream sluice valve.	To replace the gate.	
On farm canal	OF(7)~(10)	The back soil had been flowing out.	B	In future, No back soil filling may collaps the on farm canal,which causes a problem for water distribution. Since the deformation may spread in the long term, it is judged that countermeasures are required in the long term.	To fill of on farm canal embankment.	
Evaluation		A	Deteriorations/damages that are already affecting the safety/stability/operation of the facilities or are feared to affect them in near future.			
		B	Deteriorations/damages that are not affecting the safety/stability/operation of the facilities at present but may affect them in the long term.			
		C	No deteriorations/damages or no signal of them			

MAGUDU DAM

<u>MAGUDU DAM (1)</u>	
	
D(1) Embankment Upstream: Disturbance of riprap, dam body exposure and erosion, growth of plants.	D(2) Embankment Downstream: Gully erosion on the downstream surface. A surface water flow path (ditch) has been created in the downstream direction.
	
D(3) Embankment Downstream: Erosion depth about 80cm, depression depth 1.8m, width 2.7m, etc.	D(4) Embankment Downstream: Erosion is also observed on both sides of the stairway on the left bank.
	
D(5) Embankment Downstream: Eroded soil and sand are flowing to the valve house slope.(Excavating around the valve house.)	D(6) Crest of Embankment: Disturbance of riprap, dam body exposure and erosion.

MAGUDU DAM (2)

D(7) Foot of slope: There are collapses due to erosion (the height of the collapses are 1.7m and 1.2m at the largest).

D(8) Foot of slope: In the original riverbed area, trees are growing but there are no signs of wetness.

D(9) Foot of slope: In the original riverbed area, trees are growing but there are no signs of wetness.

D(10) Foot of slope: In the downstream, a small stream is observed and connects to the connecting canal (on the flowbed, reddish brown and a film is also observed).

D(11) Right side abutment: There is no disturbance in the abutment. The land is high mountain. There is farmland on the downstream side.

D(12) Right side abutment: At the boundary of the spillway, no disturbance is observed.

MAGUDU DAM (3)

	
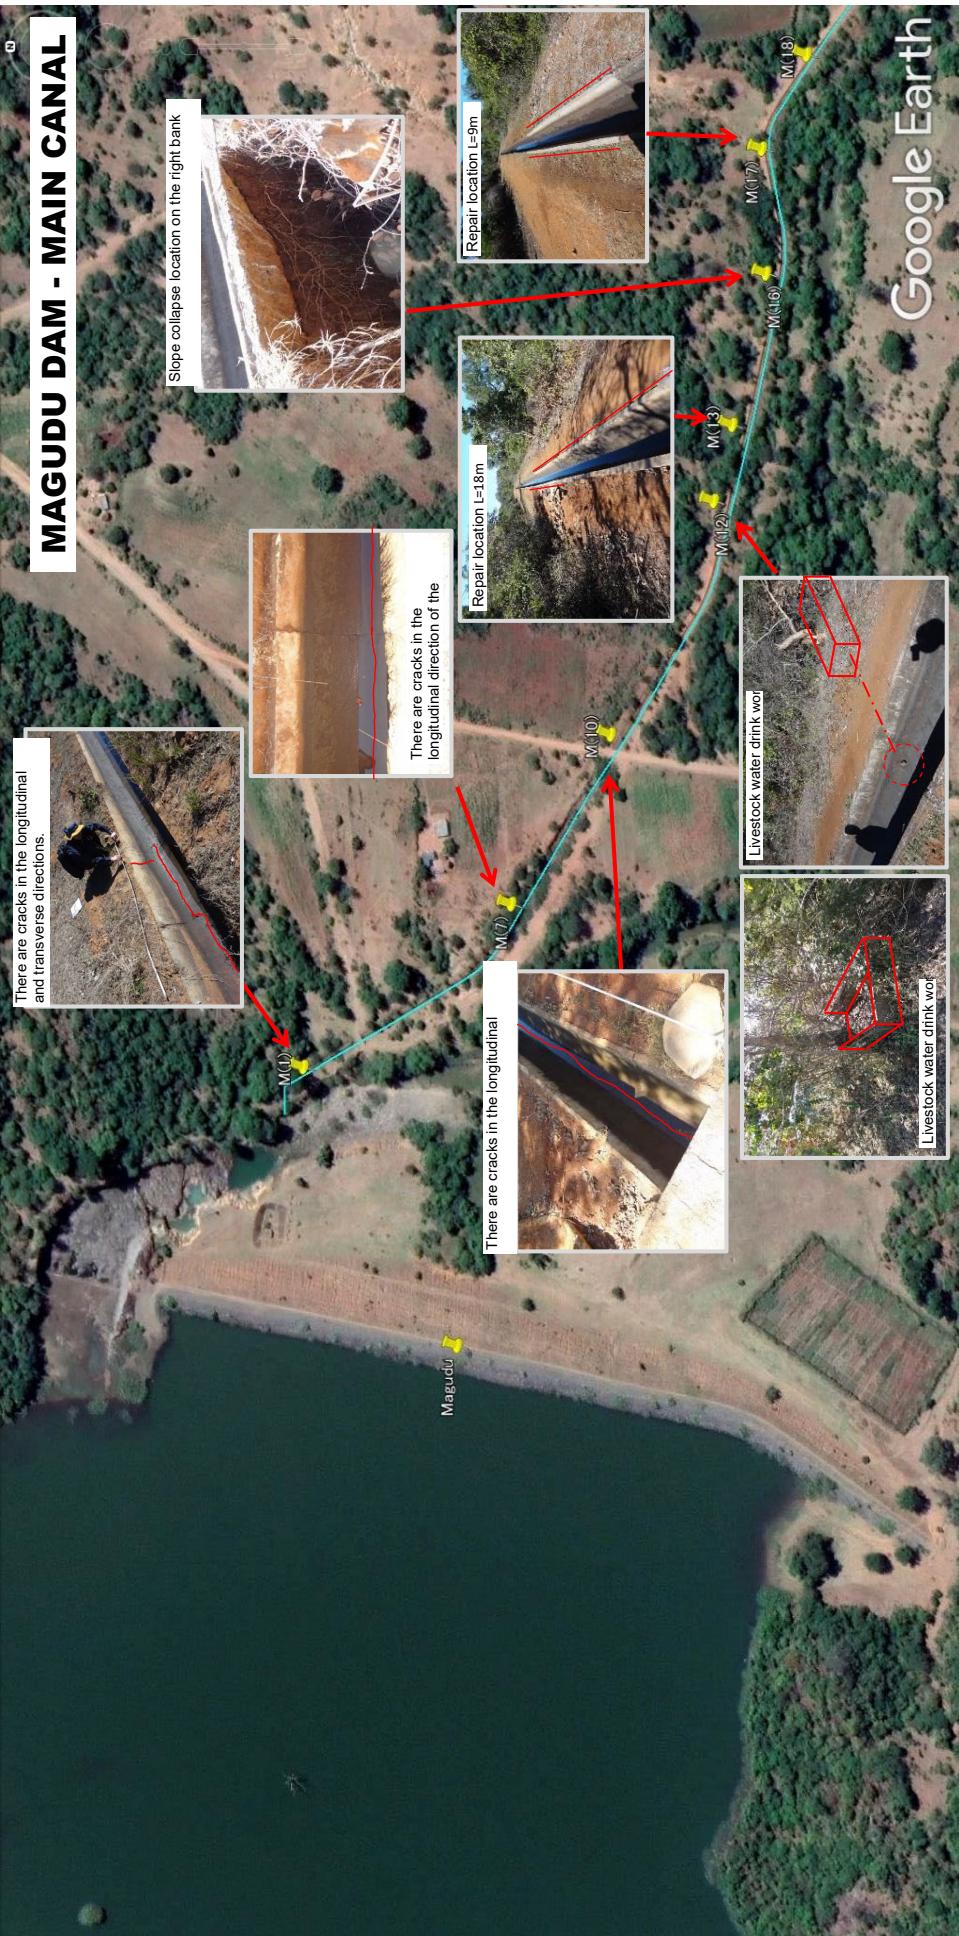

<p>S(1) Spillway entire: No significant damage is observed.</p>	<p>S(2) Spillway Weir: Surface concrete peeling at the top of the weir.(L7.5m/t5cm)</p>
	
<p>S(3) Spillway Weir: Surface concrete peeling at the top of the weir.(L7.5m/t5cm)</p>	<p>S(4) Spillway Weir: Surface concrete peeling at the downstream of the weir.(h50cm/ t5cm)</p>
	
<p>S(5) Spillway Retaining wall(Right side): No significant damage is observed.</p>	<p>S(6) Spillway Retaining wall(Left side): No significant damage is observed.</p>

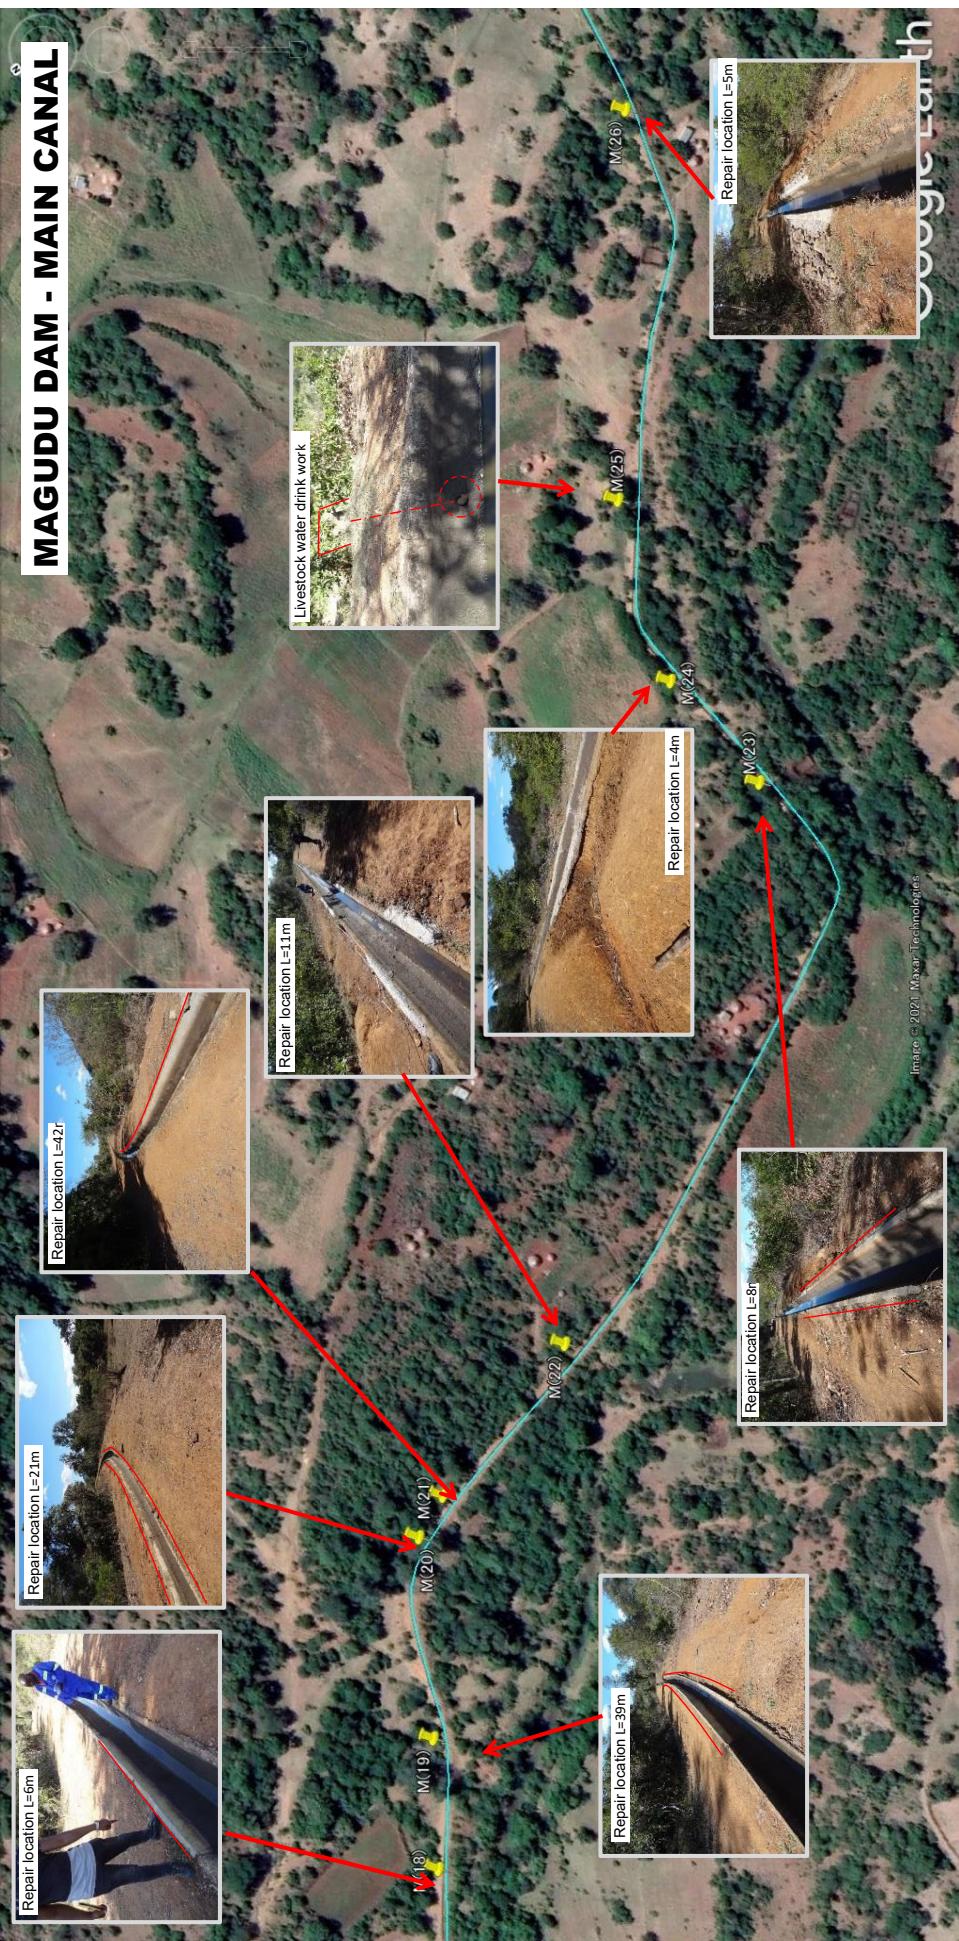

MAGUDU DAM (4)

	
<p>S(7) Spillway Apron: No significant damage is observed.</p>	<p>I(1) Intake Inlet: There are no water intake facilities left.</p>
	
<p>C(1) Connecting Canal: The large erosion is observed on the right bank side (embankment side). According to the existing photo data, the bank is eroded by about 70cm every year.</p>	<p>C(2) Connecting Canal: The large erosion is observed on the right bank side (embankment side). According to the existing photo data, the bank is eroded by about 70cm every year.</p>
	
<p>C(3) Connecting Canal: The large erosion is observed on the right bank side (embankment side).</p>	<p>C(4) Connecting Canal: The large erosion on the right bank side (embankment side) extends beside of the valve house.</p>

MAGUDU DAM (5)

	
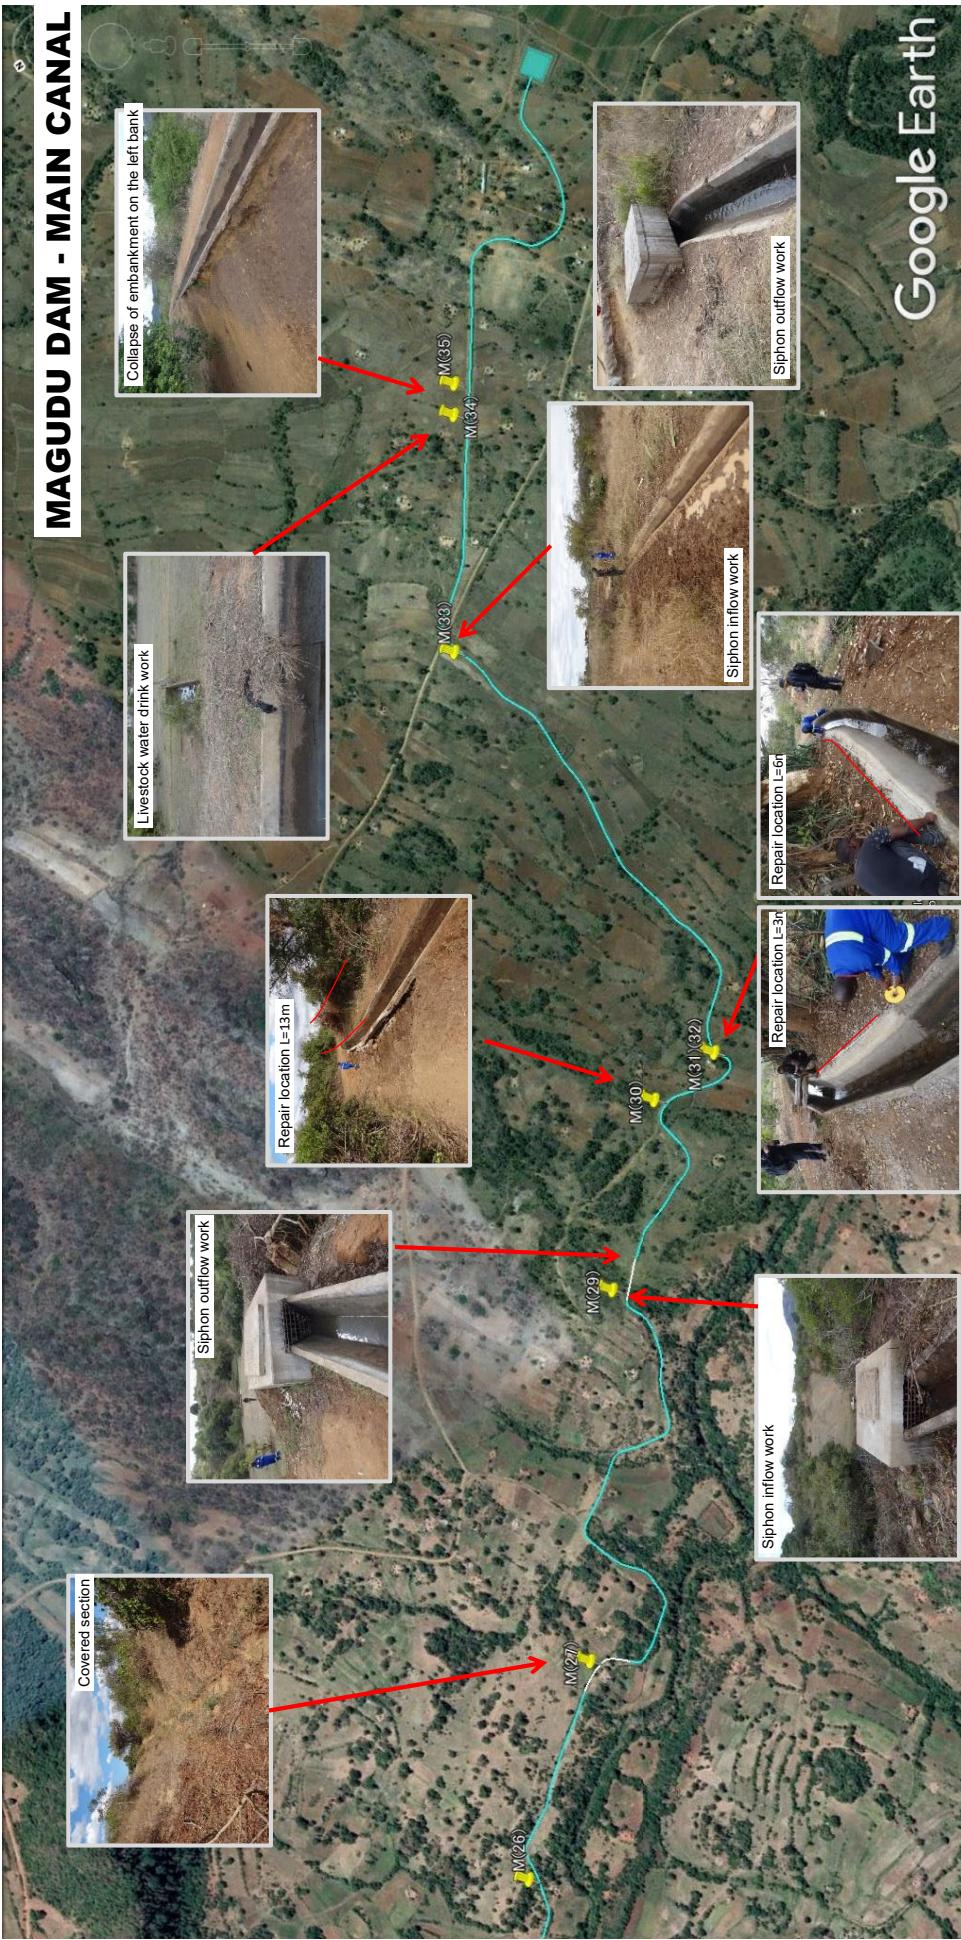

C(5) Connecting Canal: Erosion is also observed on the left bank side (downstream). The bridge has been washed away.	C(6) Connecting Canal: The canal bed has been eroded and the concrete siphon protection are exposed.
	
C(7) Connecting Canal: The erosion on the right bank side has reached the slope of the valve house.	C(8) Connecting Canal:
	
I(1):Inlet: There are no water intake facilities left.	I(2):Outlet (Valve):Good condition.

Google Earth

MAGUDU DAM - MAIN CANAL

MAGUDU - ON FARM (1)

Night strage body is good condition, but it has a little sedimentation.

OF(1):Night storage(1)

Night strage body is good condition, but it has a little sedimentation at inlet.

OF(2):Night strage(2)

Situation of sedimentation at inlet.

OF(3):Night strage(3)

The upstream gate has broken.

OF(4):Night strage(Upstream gate)

The downstream valve is movable and in good condition.

OF(5):Night strage(Outlet valve)

Good condition.

OF(6):Night strage(Spillway)

MAGUDU - ON FARM (2)

The Canal is in good condition. But there is no embankment on the field side in the entire deliver canal.

OF(7):On farm canal(1)

There are repaired On farm canal by FAO in 2018.

OF(8):On farm canal(2)

Good condition.

OF(7):Diversion(1)

Good condition.

OF(8)Diversion(2)

The back soil is flowing out.

OF(9):On farm canal(3)

The end of the distribution channel is blocked by soil embankment.

OF(10):On farm canal(4)

附属資料-1-2

ムサベレマダム

MUSAVEREMA DAM record of site survey

As of FWL-0.60m

EMBANKMENT	Location	Photo No.	Condition	Evaluation		Management: ZINWA
					Proposed Measures	
Upstream	D(1) D(2)		Disturbance of riprap, Dam body exposure and erosion Gully erosion under the riprap which is filled by rocks. Many trees on the edge of the embankment (This makes it impossible to see and pass through, especially on the left side.)	B	Even under high water level conditions, there is no seepage from the downstream slope, so it is judged that there is no impact on the water storage function at this time. However, since erosion and the growth of plants may accelerate the erosion of the embankment, it is judged that measures are required in the long term.	In order to prevent the erosion and collapse from recurring, the surface layer should be reshaped with embankment materials, and anti-erosion materials and riprap should be laid. In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.
			Gully erosion on the downstream surface. Downstream flow (ditch) formed by surface runoff is also observed. (h20cm) Many trees on the left side of the embankment (This makes it impossible to see and pass through, especially on the left side.)	B	Even under high water level conditions, there is no seepage from the downstream slope, so it is judged that there is concern that the cross-section of the embankment will shrink in the future due to the progress of erosion, it is judged that countermeasures are required in the long term.	To prevent the recurrence of erosion and collapse, reshape the surface layer with embankment materials and install anti-erosion materials and riprap. Alternatively, a new bearing canal can be installed at the top, small step, and at the edge of the slope. In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.
Downstream	D(2) D(3)		Disturbance of riprap. Many trees on the both edges. (This makes it impossible to see and pass through, especially on the left side.)	B	Even under high water level conditions, there is no seepage on the downstream surface, so it is judged that the water storage function is not affected. However, the exposure of the soil and the growth of plants may accelerate the erosion of the embankment, so it is judged that measures are required in the long term.	Re-establish rip-rap and trim trees. In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.
			D(4) D(5)	B	Even under high water level conditions, the volume of leakage is small, so it is judged that the water storage function is not affected.	Not required: Continue regular monitoring.
Foot of slope	D(6)		The downstream side about 15m from the edge is a wetland. The bed turned reddish brown and a iron bacteria film could be seen. No flow is observed.	C	Even under high water level conditions, the volume of leakage is small, so it is judged that the water storage function is not affected.	Not required: Continue regular monitoring.
	D(7)		No significant damage. Abutment area around edge of crest is flat.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.	

MUSAVEREMA DAM record of site survey

As of FWL-0.60m

Location	Photo No.	Condition	Evaluation	Proposed Measures
Left side abutment	D(8)	Many trees on and around embankment surface (higher than FWL) making it impossible to look out over and pass through. Out side of edge is flat.	B	Since plant growth is significant above the FWL, it is judged that the water storage function is not affected at this time. However, due to the plant's preventing proper monitoring and detection of alterations, it is determined that measures are needed in the long term.
SPILLWAY				
Crest	S(1) S(2) S(3) S(4)	Surface peeling and lack of stones on the top A slight plants on the left bank side	B	The damages are small and do not affect the functioning of the facility at this time, but it is judged to require countermeasures in the long term because of the possibility that the damage will increase with long-term use.
Apron	S(7) S(8)	No significant damage.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.
retaining wall	S(5) S(6)	No significant damage.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.
Canal	-	-	-	-
SPILLWAY CHANNEL				
All over the structure		No significant damage is observed.	C	Since no significant deformation is observed, it is judged that no countermeasures are necessary.
CONNECTION CANAL				
Right side	C(1)	The collapses in both side (those are seen new and being progressing. There are no private houses or other structures in the surrounding area.) Crossing road across canal.	B	As there are no important structures in the surrounding area, immediate countermeasures are not required. However, since there is a possibility that the collapse will progress due to long-term use and affect the surrounding walk ways, etc., it is judged that countermeasures are required in the long term.
Left side	C(2)		B	It is also necessary to prevent them from entering the canal. Construct a bridge.
Management: ZINWA				
				To reduce flood velocities and prevent erosion, an attenuation facility can be installed downstream of the weir (rock excavation surface).

MUSAVEREMA DAM record of site survey

As of FWL-0.60m

Location	Photo No.	Condition	Evaluation		Proposed Measures
			Management: ZINWA		
INTAKE	I(1)	The winch is still in place, but the wires are disappeared. There is rusting all over. The handle on the right bank side is movable.	B	The water inlet remains open and the volume of water intake can be controlled by the valve downstream, so there is no impact on the functioning of the system at this time. However, the water cannot be shut off when the valve downstream needs to be repaired, etc., so it is judged that countermeasures are required in the long term.	Install a new spare valve on the downstream side.
	I(2)~(3)	The valve house cannot be drained, so it has been submerged.	C	The valve maintenance has been difficult, but submerged valve is able to be resistant to corrosion.	To keep continuous monitoring.
MAIN CANAL	M(1)~(37)	There are some cracks on the crest and some gaps.	C	The main canal is unreinforced concrete and no water leakage is observed in the surrounding area, so observation is required. The main canal has been maintained. Farmer has been cleaned the main canal twice a year.	To keep continuous monitoring.
					Management: IMC
ON FARM Facilities	OF(1)~(2)(5)	The night storage is in good condition.	C	The night storage has been cleaned once a year.	To keep continuous monitoring.
	OF(3)	The inlet gate has been broken.	B	The outlet valve cannot be maintained easily. It is not mandatory to install it. This is because when maintaining the outlet valve, the water level in the night storage should be lowered.	To replace the gate.
Night storage	OF(4)	The original outlet valve has been in no-good condition.	B	The original outlet valve should be maintained. fortunately, the secondary outlet valve installed in 2020 is still in use.	To maintain the valve.
On farm canal	OF(6)~(12)	The on farm canal is in good condition.	C	The on farm canal has been maintained by farmers committee. Farmer pay the commitment fee which is \$100.1ha/year.	To keep continuous monitoring.

MUSAVEREMA DAM record of site survey

As of FWL-0.60m

Location	Photo No.	Condition	Evaluation		Proposed Measures
			Evaluation	Comments	
OTHERS					
Barbed-wire fence		The scheme fence has been reduced in strength.	-	The scheme chairman would like to support the replacement of the 5km long barbed-wire fence.	-
Bridge	O(1)	There is also bridge downstream, but this is submerged and impassable during the rainy season, making it impossible to get to school.	C	Since no significant deformation is observed. (It is necessary to prevent them from entering the canal.)	*To prevent to entering the canal, construct a new safe bridge.

附属資料-1-3

チニヤマツムワダム

CHINYAMATUMA DAM record of site survey

***As of FWL-0.20m**

Location	Photo No.	Condition	Evaluation	Proposed Measures
EMBANKMENT		Management: ZINWA		
Upstream	D(1)	Dam body exposure, gully erosion under riprap, and trees.	B	Since there is no significant collapse or sinking, it is judged that the water storage function is not affected. However, the exposure of embankment materials and the growth of plants may accelerate the erosion of the embankment, so it is judged that measures are required in the long term.
Downstream	D(2) D(3) D(4) D(5) D(6)	Dam body exposure, gully erosion under riprap, and trees. Below the first step, there are several sinks (collapsed embankment material is filled with rock material. The largest one is about B2.0m.) In the lower part of it, the soil is exposed in some places. There is no visible seepage or wetting of the slope.	B	Even under high water level conditions, there is no seepage from the slope, so it is judged that there is no effect on the water storage function at present. However, there is a concern about erosion and sinking, causing the reduction of the embankment in the future, so it is judged that measures are required in the long term.
Crest of dam	D(7)	Seepage and slight flow at the downstream slope edge. Around here, there are parts where the plants are different from those around them.	C	Since no significant damage is observed, no measures are required.
Foot of slope	D(8)	It is a wetland. The bed is turned reddish brown and a film of iron bacteria can be seen. The flow is slight.	C	Since the amount of leakage is small and the water storage function is maintained, it is judged that no measures are necessary.
Right side abutment	D(9)	No significant damages are observed. Elevation difference is small (hill-like terrain).	C	Since no significant damage is observed, no measures are required.
Left side abutment	D(10)	No significant damages are observed at the boundary with the spillway. Elevation difference is small (hill-like terrain). There is farmland in the upstream side.	C	Since no significant damage is observed, no measures are required.

CHINYAMATUMA DAM record of site survey

*As of FWL-0.20m

Location	Photo No.	Condition	Evaluation	Proposed Measures
SPILLWAY				
Crest	S(1)	Slight damage on the crest	B	Since the damage is small and leakage is less than that affecting the water storage capacity, it is judged that there is no affect on the function at present.
	S(2)	Leakage on the downstream side	C	However, since the damage may expand due to long-term use, it is judged that measures are required in the long term.
	S(3)			
Apron	S(4)	Small rocks, a slight plants, and some water are observed.	C	Since the damage is slight, it is judged that no countermeasures are required.
Retaining walls	S(5) S(6)	No significant damages are observed.	C	Since no significant damage is observed, no measures are required.
SPILLWAY CHANNEL				
Canal	S(7)	Small rocks, a slight plants, and some water are observed.	C	Since the damage is slight, it is judged that no countermeasures are required.
CONNECTION CANAL				
Right bank side	C(1)	No significant damages are observed. A slight leak can be seen, which seems to have flowed down the back of the canal.	B	As for the collapse at the end of the spillway canal, it is judged that no urgent measures are required at this time, as there is enough distance from the embankment and houses, and no rapid progress can be identified.
	C(2)	Collapse of both banks at the end of the spillway canal(right: L5m,B1.5m,H6m left: L4m,B3.5m,H6m).		However, if the collapse progresses due to long-term use, it may affect the sidewalk on the left side of the river, so it is judged that measures are required in the long term.
	C(3)			Also, entering the canal must be prohibited.
	C(4)			
INTAKE				
Inlet	I(1)	The flap valve at the inflow port stays open all the time. It has been stolen.	B	The water inlet is remain open and the intake volume can be controlled by the downstream valve, so there is no affect on the function at present.
Outlet	I(2)	The valve has movable and submerged.	C	However, since the water cannot be shut off when the downstream valve needs to be repaired, it is judged that measures will be required in the long term.
				To keep continuous monitoring.

CHINYAMATUMA DAM record of site survey

***As of FWL-0.20m**

Location	Photo No.	Condition	Evaluation		Proposed Measures
Pump	PS(1) ~(10)	FAO upgraded from two (2) diesel pumps to two (2) electric pumps in 2016. The replaced pump cannot deliver required volume to the night storage due to insufficient electricity current volume.	B	The Power current is low (55-60A) and requires about 80A. This due to transmission loss since transformer is located 500m away from the pump station.	Replace the transformer.
PIPE LINE					
Pipeline	PL(1) ~(7)	The pipeline is properly maintained.	C	There is no water leakage from the pipeline, so there is no problem.	To keep continuous monitoring.
Air valve	PL(3)(5)	The one(1) air valve is in good condition, but the other has a very small amount of leakage.	B	Two air valves are no problem with water flow. The air valves are checked by FAO in 2016. But it is not necessary to measures immediately.	To maintain the air valve.
ON FARM Facilities					
Night storage	OF(1) ~(5)	No sedimentation and good condition. Night storage is properly maintained.	C	There is no water leakage from the night storage, and no sedimentation, so there is no problem in future.	To keep continuous monitoring.
On farm canal	OF(6) ~(14)	The on farm canal has not been distributed for more than 5 years and is not maintained. The distribution canal embankment on the back is flowing out.	B	The lack of on farm canal embankment is in danger of collapsing. But it is not necessary to measures immediately.	To fill of on farm canal embankment.
OTHERS					
			-		

Evaluation A Deteriorations/damages that are already affecting the safety/stability/operation of the facilities or are feared to affect them in near future.

 B Deteriorations/damages that are not affecting the safety/stability/operation of the facilities at present but may affect them in the long term.

 C No deteriorations/damages or no signal of them

Chinyamatumwa Dam

CHINYAMATUMWA DAM (1)

	
D(1) Embankment Upstream:Dam body exposure, gully erosion under riprap, and trees.	D(2) Embankment Dam body exposure, gully erosion under riprap, and trees.
	
D(3) Embankment Downstream:Below the first step, there are several sinks (collapsed embankment material is filled with rock material). The largest one is about B2.0m.).In the lower part of it, the soil is exposed in some places.	D(4) Embankment Downstream(left):Seepage at the downstream slope edge.
	
D(5) Embankment Downstream(right):Seepage and slight flow at the downstream slope edge.	D(6) Embankment Downstream:Seepage and slight flow at the downstream slope edge. Around here, there are parts where the plants are different from those around them.

CHINYAMATUMWA DAM (2)

	
D(7) Crest of Embankment: Since no significant damage is observed.	D(8) Foot of slope: It is a wetland. The bed is turned reddish brown and a film of iron bacteria can be seen. The flow is slight.
	
D(9) Right side abutment: No significant damages are observed. Elevation difference is small (hill-like terrain).	D(10) Left side abutment: No significant damages are observed at the boundary with the spillway. Elevation difference is small (hill-like terrain). There is farmland in the upstream side.
	
S(1) Spillway entire: No significant damages are observed.	S(2) Spillway weir: Slight damage on the crest.

<u>CHINYAMATUMWADAM (3)</u>	
	
S(3) Spillway weir: Leakage on the downstream side	S(4) Spillway apron: Small rocks, a slight plants, and some water are observed.
	
S(5) Spillway Retaining walls(right): No significant damages are observed.	S(6) Spillway Retaining walls(left): No significant damages are observed.
	
S(7) Spillway canal: Small rocks, a slight plants, and some water are observed.	

CHINYAMATUMWA DAM (4)

	
I(1) Intake Inlet: The flap valve at the inflow port stays open all the time, It has been stolen.	I(2) Intake Outlet: The valve has movable and submerged.
	
C(1) Connecting Canal: No significant damages are observed. A slight leak can be seen, which seems to have flowed down the back of the canal.	C(2) Connecting Canal: Crossing road across canal
	
C(3) Connecting Canal: Collapse of both banks at the end of the spillway canal (right: L5m,B1.5m,H6m).	C(4) Connecting Canal: Collapse of both banks at the end of the spillway canal (left: L4m,B3.5m,H6m).

マショコダム

MASHOKO DAM record of site survey

As of FWL-0.55m

Location	Photo No.	Condition	Evaluation	Proposed Measures
EMBANKMENT				
Upstream	D(1)	Many trees (making it impossible to see the condition of the surface). Partially disturbed riprap and exposure of dam body.	B	Even under high water level conditions, no seepage is observed, so it is judged that the water storage function is not affected at this time.
Downstream	D(2)		B	However, the growth of trees may cause water leakage inside the embankment, and also prevent the detection of slope sinking, cracks, and seepage by inspection. In addition, the disturbance of the riprap can be a cause of erosion due to rainfall.
Crest of dam	D(3)		B	Considering the above, it is judged that the stability and safety of the embankment may be affected by long-term use, and therefore long-term measures are required.
Foot of slope	D(4)	Wetness is observed, but there is no flow.	C	Even under high water level conditions, no significant water leakage was observed, so it is judged that no measures are required.
Right side abutment	D(5)	Many trees (making it impossible to see the condition of the surface). No damage is observed at the boundary between the abutment and the crest (like a hill). There is a house in the downstream.	C	Since no significant damage is observed, no measures are required.
Left side abutment	D(6)		C	Since no significant damage is observed, no measures are required.
SPILLWAY				
Crest	S(1) S(2)	No significant damage.	C	Since no significant damage is observed, no measures are required.
Apron	S(5) S(6)	A few rocks and cracks are observed on the bottom. There is no scouring at the bed. Low plants in joints.	C	Although slight damages are observed, it is judged that no measures are required because it does not affect the function or stability of the system.
Retaining wall	S(3) S(4)	Efflorescence from cracks (not draining from drainage holes).	C	Although slight damage is observed, it is judged that no measures are required because it does not affect the function or stability of the system.
SPILLWAY CHANNEL				
Canal	S(7) S(8)	The end of the spillway canal is a gabion works of L4.5m (150cm). There is no erosion. Crossing road across canal.	B	At present, there are no significant changes. However, it is judged that measures are required in the long term, since entering the canal should be prohibited and it also leads to deterioration of the gabions.
Management: ZINWA				
				A bridge will be built to cross the river.

MASHOKO DAM record of site survey

As of FWL-0.55m

Location	Photo No.	Condition	Evaluation	Proposed Measures
CONNECTION CANAL				
Right side		No significant damage is observed.	C	Since no significant damage is observed, no measures are required.
Left side		No significant damage is observed.	C	Since no significant damage is observed, no measures are required.
INTAKE				
Inlet	I(1)	Missing of the wires (The water can be taken. Gate is fully open anytime it cannot be controlled). Rusting all over	B	The water inlet is remain open and the intake volume can be controlled by the downstream valve, so there is no effect on the function at present. However, since the water cannot be shut off when the downstream valve needs to be repaired, it is judged that measures will be required in the long term.
Outlet	I(2)	The valve is movable and there is no problem.	C	The valve is moving and there is slight rust, but it is not necessary to measures.
MAIN CANAL				
Whole line	M(1)~(10)	The main canal has been rebuilt on the wall of the original channel at a height of 150 mm.	C	The main canal has been good maintenance.
ON FARM Facilities				
Night storage	OF(1)~(4)	The night storage is in good condition. The outlet valve is movable. The spillway is in good condition.	C	The night storage has been good maintenance.
On farm canal	OF(5)(6)~(12)	The on farm canal back soil has been flowied out.	B	No emergency action is required, but further deformation can cause damage.
On farm canal	OF(7)	The sluice gate has been broken.	B	The gate on the main channel is out of order, since a small effect on the water supply, urgent measures are not necessary.
On farm canal	OF(8)	The diversion has a small amount of water leaks.	C	The diversion has leakage, but this leakage is too small amount. Thus it is not necessary to measures.

MABVUTE DAM record of site survey

As of FWL-0.40m

EMBANKMENT	Location	Photo No.	Condition	Evaluation		Management: ZINWA
					Proposed Measures	
Upstream	D(1)	Exposure of dam body, gully erosion under riprap, and trees.	B	No significant collapse was observed, and it is judged that there is no affect on the water storage function. However, the sinks and growth of plants may lead to the erosion of the embankment, so it is judged that measures are required in the long term.	In order to prevent the erosion and collapse from recurring, the surface layer should be reshaped with embankment materials, and anti-erosion materials and riprap should be laid.	
Downstream	D(2) D(3) D(4) D(5) D(6)	Riprap is disturbed and dam body is exposed near the crest, edge, and paths. Many trees in the left side. Gully erosion under riprap makes downstream ditch which is filled with rocks. Lower those area, dam body is exposed but there is no seepage. At the both side of slope edge, there are flow route and those eroded the edge. (No flow or wetness.)	B	Even under the high water level condition, there is no seepage on the slope, so it is judged that the water storage function is not affected. However, the collapse of the riprap and the exposure of the embankment materials will lead to the erosion and the reduction of the embankment, so it is judged that measures will be required in the long term.	In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.	
Crest of dam	D(9) D(10)	There are small amount of trees in the left side.	C	No significant damage is observed, and it is judged that there is no affect on the water storage function. However, the growth of plants may lead to the erosion of the embankment, so it is judged that measures are required in the long term.	Trim trees. In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.	
Foot of slope	D(7) D(8)	It is a wetland. The bottom turns reddish brown and a film of iron bacteria can be seen. The flow is slight.	C	Even under high water level conditions, the volume of leakage is small, so it is judged that the water storage function is not affected.	Not required: Continue regular monitoring.	
Right side abutment	D(11)	No significant damage is observed. The abutment around the edge of the crest is flat.	C	Since no significant damage is observed, no measures are required.	Not required: Continue regular monitoring.	
Left side abutment	D(12)	No significant damage is observed between embankment and spillway. The abutment is about 1m higher than the crest, and around there is flat.	C	Since no significant damage is observed, no measures are required.	Not required: Continue regular monitoring.	

MABVUTE DAM record of site survey

As of FWL-0.40m

Location	Photo No.	Condition	Evaluation		Management: ZINWA
				Proposed Measures	
SPILLWAY					
Crest	S(2) S(3) S(4)	Only slight damage (lack of stone) is observed on the top of weir. There is small leakage from crack on the downstream, no flow can be seen. Slight plants on the left side of weir.	C	Since the damage is slight, it does not affect the function, and there is no serious risk of expansion in the long term, so it is judged that no measures are required.	Not required: Continue regular monitoring.
	S(5) S(6)	No scour is observed, and small rocks, plants, and open joints can be observed. Stones are deposited at the upstream end.	C	Since the damage is slight, it is judged that it does not affect the function and no immediate measures are required. Detachment of joint materials and growth of plants may become weak points in floods and cause more damage, so it is judged that measures are required in the long term.	Conduct joint filling work. Cut down and remove boulders.
Apron	S(7) S(8)	Efflorescence is observed. On the left bank side, leakage of seepage water from the ground (water can be seen, but there is no flow).	C	Since the damage is slight, it does not affect the function, and there is no serious risk of expansion in the long term, so it is judged that no measures are required.	Not required: Continue regular monitoring.
	S(9) S(10)	There is a slight leak from the back of the canal. Although there is no gabion, it may be the result of previous gabions that were washed away because of the rock material scattered around there.	C		
SPILLWAY CHANNEL					
Canal				Since there are no factors of interfering with flow, it is judged that immediate measures are not required.	Not required: Continue regular monitoring.
CONNECTION CANAL					
Right side	C(1)	No significant damage is observed.	C	Since no significant damage is observed, no measures are required.	Not required: Continue regular monitoring.
	C(2) C(3)	Collapses next to the spillway canal, but those does not seem to be in progress(L10.0m,B3.0m,H7.0m). Although the canal is used as a road to school, children cannot go to school during the rainy season because of the flow.	B	Since the collapse is small, it is judged that the drainage function is not affected. However, the collapse may progress and affect the surrounding area due to long-term use, and therefore, it is judged that long-term measures are required. In addition, entering into the canal should be prevented.	A retaining wall will be built in the collapsed area using stone masonry. The end of the spillway canal will be improved as a drop-off and pond. A bridge will be built to cross the canal.

MABVUTE DAM record of site survey

EMBANKMENT			Evaluation		Proposed Measures	
Location	Photo No.	Condition			Management: ZINWA	
Upstream	D(1)	Overall, there is limited plant growth, but relatively thick trees are found only near the edge of the left bank (elevation above FWL at the abutment). There is almost no collapse of riprap or exposure of embankment materials.	B	No significant collapse was observed, and it is judged that there is no affect on the water storage function. However, the growth of plants may lead to the erosion of the embankment, so it is judged that measures are required in the long term.	In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.	Trim trees.
Downstream	D(2) D(3) D(4)	Erosion under riprap makes downstream ditches filled with rocks). In the lower part of those area, fine particles of embankment material are deposited (there is no seepage). Especially at the lower part of the steps, the riprap is relatively thin and there is a lot of plants. Relatively thick trees are found only near the edge of the left bank (elevation above FWL at the abutment). Exposed embankment material on walkways.	B	Even under the high water level condition, there is no seepage on the slope, so it is judged that the water storage function is not affected. However, the erosion and sinking will lead to the reduction of the embankment, so it is judged that measures will be required in the long term.	In order to prevent the erosion and collapse from recurring, the surface layer should be reshaped with embankment materials, and anti-erosion materials and riprap should be laid.	In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.
Crest of dam	D(5)	Overall, there is limited plant growth.	C	No significant collapse was observed, and it is judged that there is no affect on the water storage function.	Trim trees.	In addition to this, it is necessary to organize regular maintenance and management systems such as tree trimming.
Foot of slope	D(6)	It is a wetland and there is a puddle of water on the downstream road. The flow is slight. The water has turned reddish brown and a film of iron bacteria can be seen.	C	Even under high water level conditions, the volume of leakage is small, so it is judged that the water storage function is not affected.	Not required: Continue regular monitoring.	Not required: Continue regular monitoring.
Right side abutment	D(7)	No significant damage is observed. The abutment is flat.	C	Since no significant damage is observed, no measures are required.	Not required: Continue regular monitoring.	Not required: Continue regular monitoring.
Left side abutment	D(8)	No significant damage is observed. The abutment is flat.	C	Since no significant damage is observed, no measures are required.	Not required: Continue regular monitoring.	Not required: Continue regular monitoring.

MUNJANGANJA DAM record of site survey

As of FWL-0.3m

Location			Photo No.			Condition			Evaluation			Proposed Measures		
SPILLWAY												Management: ZINWA		
Crest	S(1) S(2)	There are slight leakages and flows from cracks on the downstream.	B	The damage is slight and does not affect the functions at this time, but it is judged that measures are required in the long term because the damage may expand due to continuous overflow.	Concrete covering shall be applied to the surface layer.									
Apron	S(5) S(6)	No cracks, plants, or washes are observed. Opening of joints (up to 3cm, detached joint material), damage to joints (60cm, 40cm), and small stones are observed.	B	The damage is slight and does not affect the function at present, but it is judged that measures will be required in the long term because this spot may become a weak point in flood and the damage may expand.	Conduct joint filling work.									
SPILLWAY CHANNEL									Management: ZINWA					
Retaining wall	S(3) S(4)	There are cracks less than 1cm width on the top of the both retaining wall.(right side L12m, left side L10m).	B	The damage is slight and does not affect the functions at present, but it is judged that measures will be required in the long term because of the risk of the damage expanding due to rainwater infiltration.	Cover the cracks.									
Canal	S(7) S(8)	There is seepage at joints and the boundary of the retaining wall (no flow is observed). The bottom of the drainage hole at the bottom of the retaining wall is wet.	C	Since no significant damage is observed, no measures are required.	Not required: Continue regular monitoring.									
Right side	C(1) C(2)	The right side of the gabions (t50cm) has been washed away. The remaining area is on the rock, but the area that was washed away is a depression with no rock visible at the bottom. It is used as a walkway for crossing:	B	At present, no collapse has been observed, and it is judged that the drainage function will not be affected. However, it is judged that measures will be required in the long term, as there is a risk that the collapse of the slopes and disturbance of the flow may occur due to long-term use. In addition, entering the canal should be prevented.	The depression is filled with stone masonry and the gabions are reinstated. A bridge will be built to cross the canal.									
CONNECTION CANAL									Management: ZINWA					
Left side	C(3) C(4)	The cages are damaged. Downstream of the gabions, there is a collapse on the left side (L1.8m, B1.2m, H3.0m).	B	Since the collapse is small, it is judged that the drainage function is not affected. However, since the collapse may progress over time and affect the surroundings, it is judged that measures are required in the long term.	A retaining wall will be built in the collapsed area using stone masonry.									

MUNJANGANJA DAM record of site survey

As of FWL-0.3m

INTAKE			Evaluation		Proposed Measures	
Location	Photo No.	Condition				
Inlet	I(1)	The building and winch are located at the crest, but the wires have disappeared. The handle can be turned.	B		The water inlet is remain open and the intake volume can be controlled by the downstream valve, so there is no affect on the function at present. However, since the water cannot be shut off when the downstream valve needs to be repaired, it is judged that measures will be required in the long term.	Install a new spare valve on the downstream side.
Outlet	I(2)	The valve is movable and there is no problem.	C		The valve is moving and there is slight rust, but it not necessary to measures.	To keep continuous monitoring.
MAIN CANAL					Management: IMC	
Siphon	M(6)(7)	The siphon is in good condition.	C		The siphon has been cleaned by farmers three times a year.	To keep continuous monitoring.
Whole line	M(1)~(37)	The main canal has some cracks on crest and some leakage.	C		The main canal has been maintained and cleaned three times a year by farmers. There is a little bit water leakage, but it is not necessary to measures.	To keep continuous monitoring.
ON FARM Facilities					Management: IMC	
Night storage	OF(1)~(4)	The night storage is in good condition. The outlet valve is movable and some leakages. The spillway is in good condition.	C		The night storage has been good maintenance. Thus it is not necessary to measures.	To keep continuous monitoring.
On farm canal	OF(5)~(12)	The on farm canal is good condition.	C		No emergency action is required.	To keep continuous monitoring.
On farm canal	OF(11)	The some sluice gates have been broken.	B		The some gates on the main channel are out of order, since a small effect on the water supply, urgent measures are not necessary.	To replace the gates.
OTHERS						
Barbed-wire fence		The scheme fence has been reduced in strength.	-		The scheme chairman would like to support the replacement of the 10km long barbed-wire fence.	-

MUNJANGANJA DAM record of site survey

As of FWL-0.3m

Location	Photo No.	Condition	Evaluation	Proposed Measures
entry road	O(1)	No damage is observed at the entry road downstream of the river.	C	Since no significant damage is observed, no measures are required. Not required: Continue regular monitoring.

- Evaluation**
- | | |
|---|---|
| A | Deteriorations/damages that are already affecting the safety/stability/operation of the facilities or are feared to affect them in near future. |
| B | Deteriorations/damages that are not affecting the safety/stability/operation of the facilities at present but may affect them in the long term. |
| C | No deteriorations/damages or no signal of them |

Munjangania Dam

MUNJANGANJA DAM (1)

	
D(1) Embankment Upstream: Overall, there is limited plant growth, but relatively thick trees are found only near the edge of the left bank (elevation above FWL at the babutment). There is almost no collapse of riprap or exposure of embankment materials.	D(2) Embankment Downstream: Especially at the lower part of the steps, the riprap is relatively thin and there is a lot of plants.
	
D(3) Embankment Downstream: Erosion under riprap makes downstream ditches(filled with rocks). In the lower part of those area, fine particles of embankment material are deposited (there is no seepage) .	D(4) Embankment Downstream: Relatively thick trees are found only near the edge of the left bank (elevation above FWL at the babutment). Exposed embankment material on walkways.
	
D(5) Crest of Embankment : Overall, there is limited plant growth, but relatively thick trees are found only near the edge of the left bank (elevation above FWL at the babutment).	D(6) Foot of slope: It is a wetland and there is a puddle of water on the downstream road. The flow is slight. The water has turned reddish brown and a film of iron bacteria can be seen.

MUNJANGANJA DAM (2)

	
D(7) Right side abutment : No significant damage is observed. The abutment is flat.	D(8) Left side abutment : No significant damage is observed. The abutment is flat.
	
S(1) Spillway entire: No significant damage is observed. The abutment is flat.	S(2) Spillway 越流堰: There are slight leakages and flows from cracks on the downstream.
	
S(3) Spillway retaining wall (right): There is a crack less than 1cm width on the top of the retaining wall. (L12m).	S(4) Spillway retaining wall (left): There is a crack less than 1cm width on the top of the retaining wall. (L10m).

MUNJANGANJA DAM (3)

	
<p>S(5) Spillway apron : No cracks, plants, or washes are observed.</p>	<p>S(6) Spillway apron : Opening of joints (up to 3cm, detached joint material), damage to joints (60cm, 40cm), and small stoners are observed.</p>
	
<p>S(7) Spillway canal: There is seepage at joints and the boundary of the retaining wall (no flow is observed).</p>	<p>S(8) Spillway canal: The bottom of the drainage hole at the bottom of the retaining wall is wet.</p>

MUNJANGANJA DAM (4)

I(1) Intake Inlet: The building and winch are located at the crest, but the wires have disappeared. The handle can be turned.

I(2) Intake Outlet: The handle has been vanished away.

I(3) Intake Outlet: The middle of spindle had been broken.

I(4) Intake Outlet: The valve has been controlled in good condition.

MUNJANGANJA DAM (5)

C(1) Connecting Canal: The right side of the gabions (t50cm) has been washed away.

C(2) Connecting Canal: The remaining area is on the rock, but the area that was washed away is a depression with no rock visible at the bottom.

C(3) Connecting Canal: The cages are damaged. It is used as a walkway for crossing.

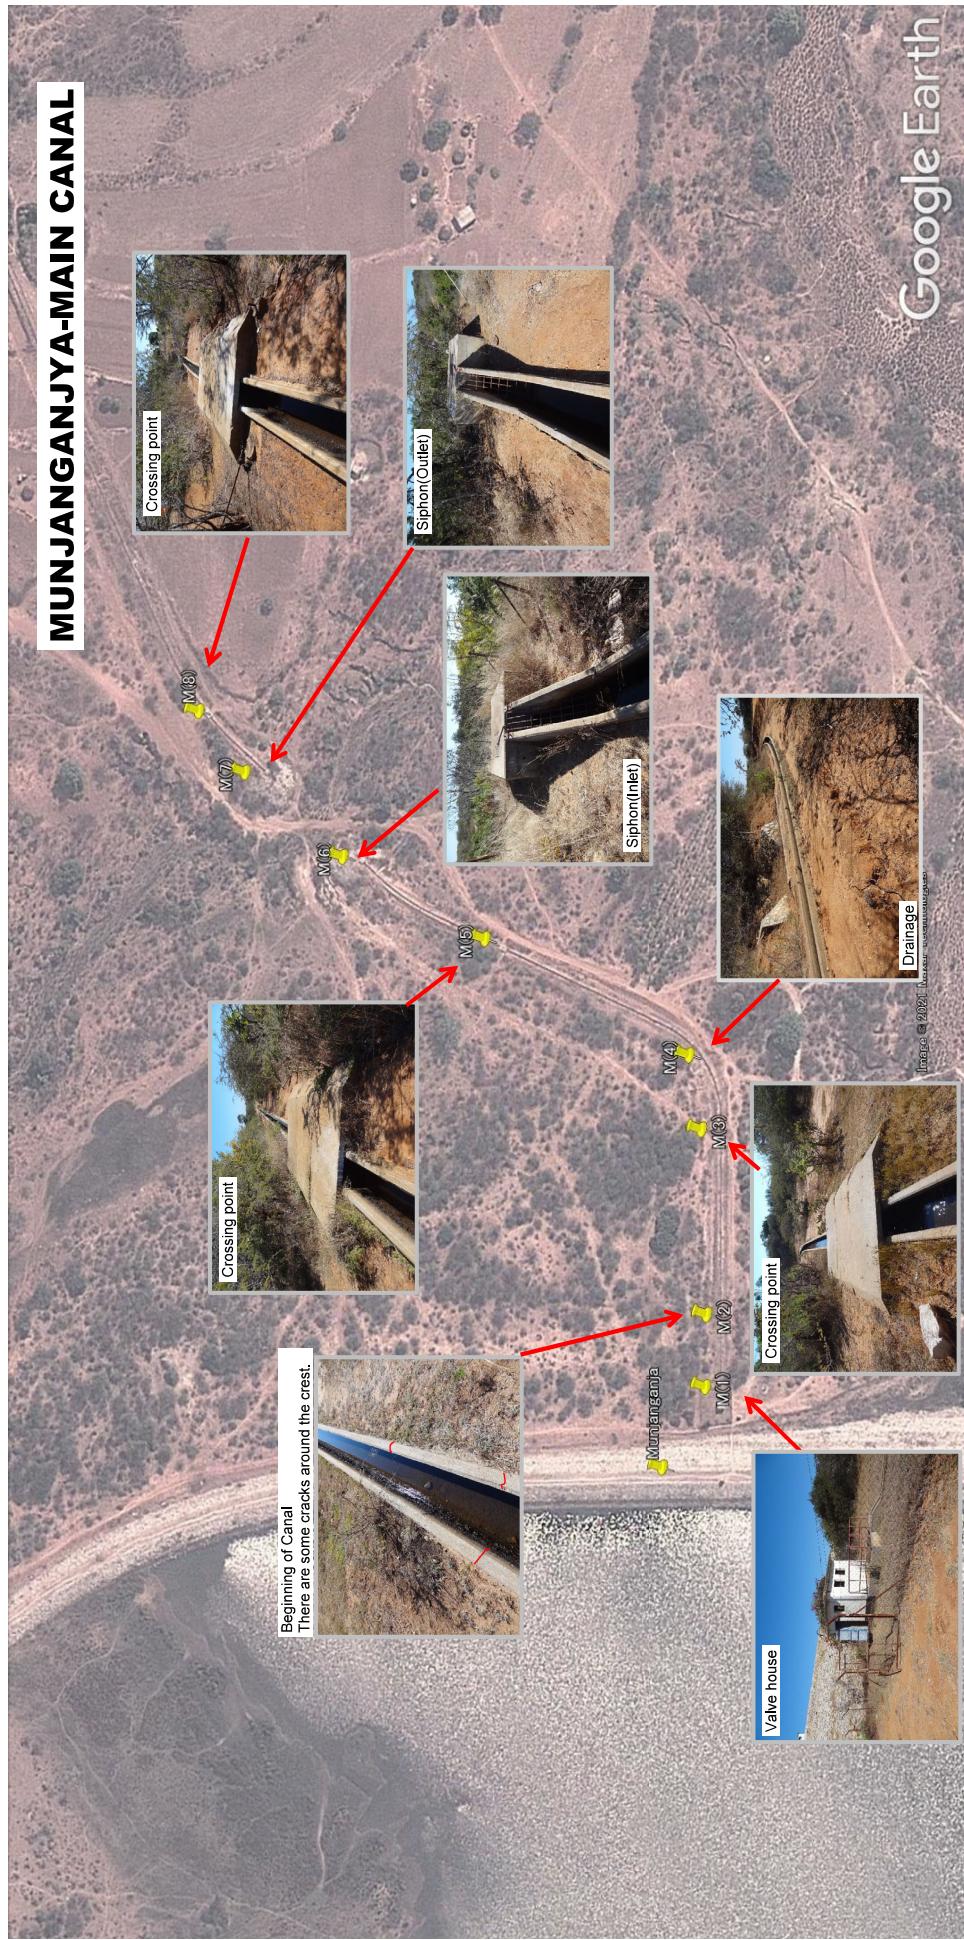

C(4) Connecting Canal: Downstream of the gabions, there is a collapse on the left side (L1.8m, B1.2m, H3.0m).

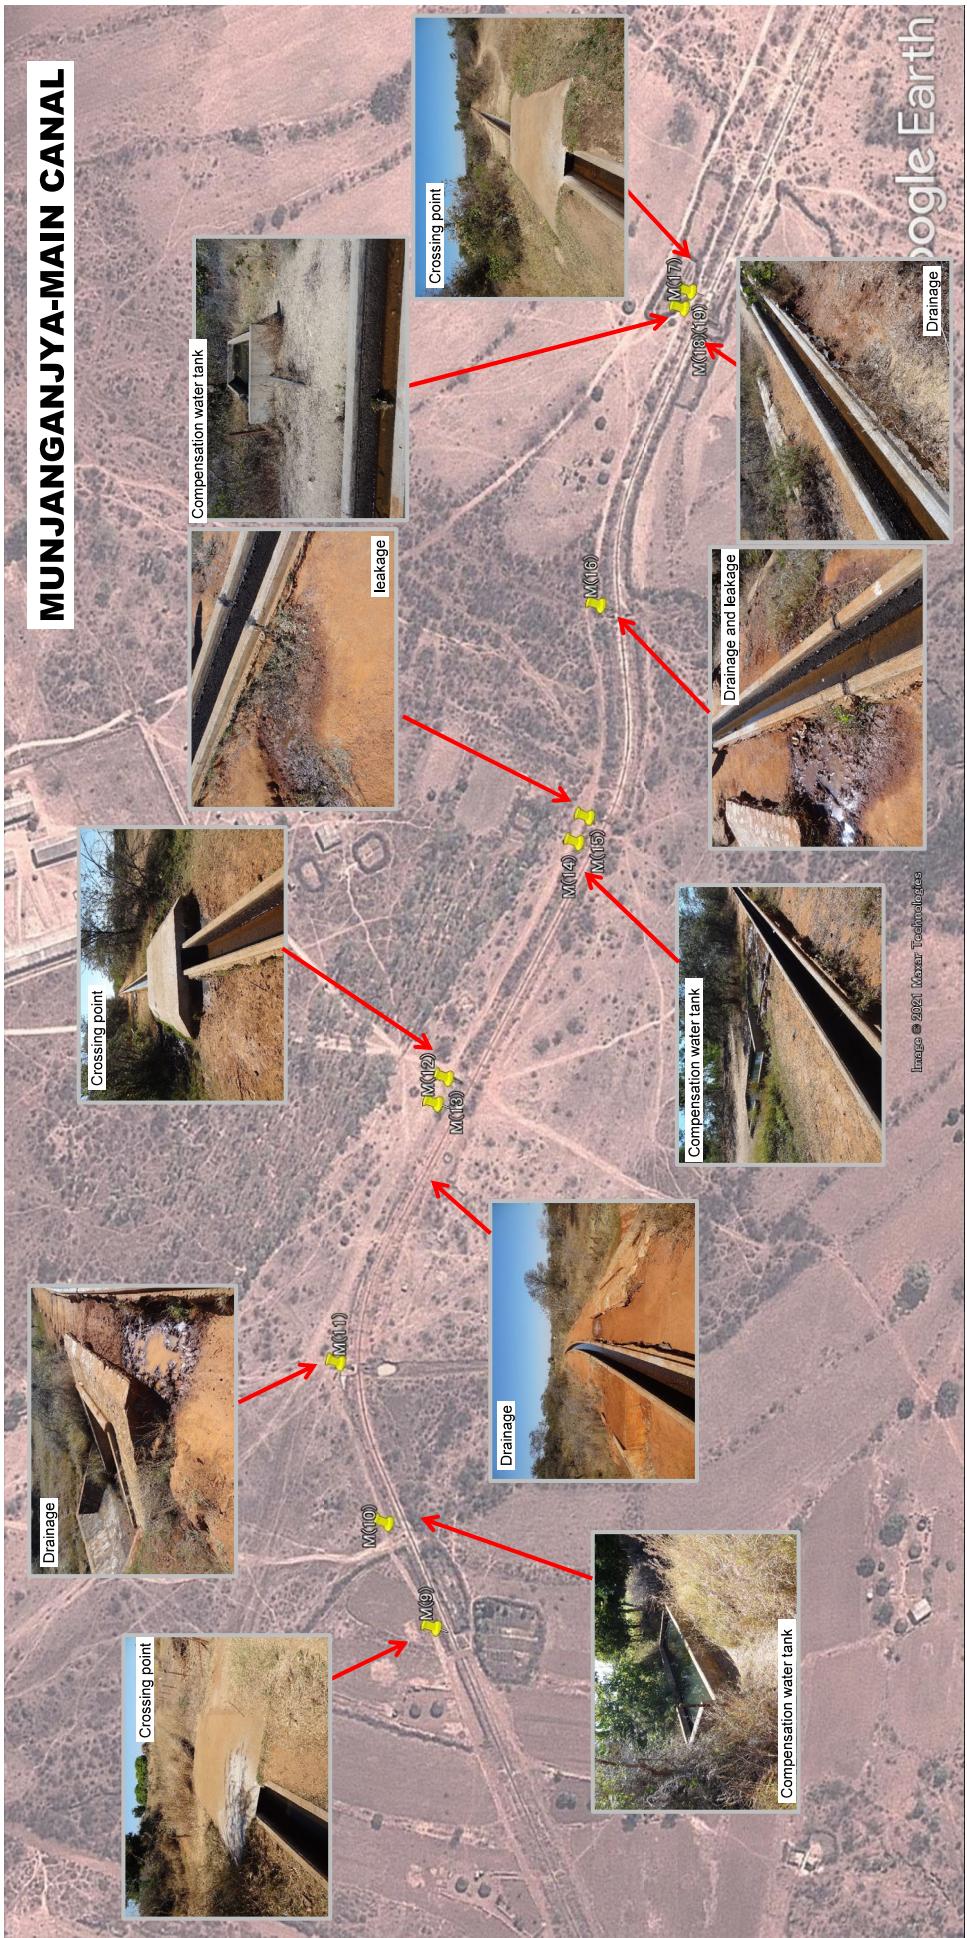

O(1) Others: No damage is observed at the entry road downstream of the river.
