FOREWORD

A symposium on the theme of "Weeds and the Environment in the Tropics" took place during the 10th Conference of the Asian-Pacific Weed Science Society (APWSS) held on November 24th to 30th, 1985, in Chiang Mai, Thailand. This symposium was a highlight of the conference. In keeping with this theme, we have strived to relate the content of all sessions and the field-trips to this subject area. Environment and weed ecology have been much published topics in recent decades and will, no doubt, assume even greater importance in the future.

Thailand, is observed to suffer from pollutive weeds throughout the country. In particular, *Mimosa pigra*, known as giant mimosa, is a prevalent pollutive weed around Chiang Mai Province, causing problems on access roads, blocking streams, filling lakes and encroaching on arable lands. Originally, *Mimosa pigra* was imported and planted for the purpose of combating soil erosion on deforested hills, serving as a fire break, and/or fencing out cattle from gardens; however, it has since become a serious problem of increasing magnitude. Besides this weed, we have other serious weeds such as *Eichhornia crassipes* in water areas and *Pennisetum* spp. in terrestrial locations.

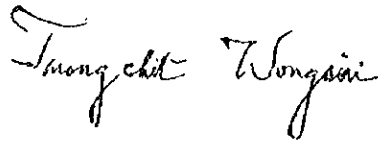

The problems of weeds and the environment are urgent and important not only in Thailand but also other countries in the tropics. It is very useful for us to meet at the symposium to pool our knowledge and exchange ideas and to learn ways of solving these problems. Based on the above considerations, the theme of this symposium was established.

Finally, concerning the holding of the symposium, I would sincerely like to acknowledge the contributions of the speakers; Dr. H. Shibayama, Dr. M. Soerjani, Dr. S.K. De Datta, Dr. L.E. Bendixen, Dr. T. Smitinand, Dr. Y.L. Chen and Dr. J. Harada, as well as of Dr. K. Noda,

ii

Dr. B.L. Mercado and Dr. K.U. Kim who served as chairmen in the symposium.

Further, I would add our sincere thanks to the Japan International Cooperation Agency who provided partial financial assistance to facilitate the success of this symposium.

PREFACE AND INTRODUCTION

A symposium entitled "Weeds and the Environment in the Tropics" was held on November 29th, 1985, for one day during the 10th Conference of the Asian-Pacific Weed Science Society (APWSS) from November 24th to 30th, 1985, at Chiang Mai, Thailand. Why was this theme determined by the Planning Committee of the 10th Conference of APWSS?

Recently, environment problems have generated much awareness among the public in not only developed countries but also developing countries, probably due to the concern about how to effectively utilize the limited area of the earth with respect to the population explosion in relation to advanced technologies in human life as well as shifting methods of agricultural production of foods and materials. When we consider the impact of weeds on the environment, two aspects can be generally taken into consideration, these are weeds themselves and advanced weed control technologies. They have already provided several environmental problems or potential problems. For instance, Thailand is now suffering from serious infestation of three pollutive weed species, *Mimosa pigra*, *Eichhornia crassipes* and *Pennisetum* spp.

(1) The impact of serious weeds themselves directly and/or indirectly on the environment. Typical, direct impacts are found with *Mimosa pigra*, *Eichhornia crassipes* and *Pennisetum* spp. already described. *Mimosa pigra* was first brought from Indonesia to serve as fire break and to fence out cattle from gardens in Chiang Mai around 30 years ago and promptly spread to the North, Northeast, and South of Thailand in water reservoirs, river banks and/or canals, as well as in wet fields of terrestrial areas. It obstructs water flow, impedes navigation, builds up sediment in water reservoirs and reduces the capacity of water resources and utilization. Much effort has been concentrated on the control and

utilization of this weed.

Eichhornia crassipes, a floating weed called water hyacinth, was also imported from Indonesia as an ornamental plant around a couple of decades ago, and is distributing throughout Thailand. Chao Phya River, Thailand's largest, is sometimes clogged by this weed, impeding navigation. Furthermore, it is considered that recent disastrous flooding in Bangkok was incidentally caused by the reduction of drainage capacity due to the remarkable prolificacy of this weed in rivers and canals on the outskirts of Bangkok. Ineffective efforts at control and utilization have been conducted not only in Thailand but also world-wide.

Further, three species of *Pennisetum*, called communist grasses, have spread all over the country due to the prolific abundance of seeds and their easy distribution by the wind. It is not only a menace in croplands but also often causes traffic accidents because of its height of as much as three meters.

Another aspect of weeds in the environment indirectly affects the environmental situation resulting in disasters associated with the human environment. For instance, weeds which may principally harbor microorganisms and insects, may play a role in their dynamic behavior, and may consequently adversely affect agricultural production of crops as well as the well-being of the people.

(2) Another aspect concerning advanced weed control technologies is exemplified by certain herbicides. Excessive application of herbicides induces environmental problems as seen in countries with heavy use such as Japan, the EC countries and the United States. Even in Thailand, increased imports of pesticides including herbicides have aroused the awareness of many persons. Professor An Nimnanbemintr, a member of the Society for the Conservation of National Treasures and Environment, notes that Thailand spent nearly 1,500 million Baht (equivalent to 60 million dollars) on pesticide imports in 1983, and that misuse of these chemicals has caused thousands of injuries and deaths each year, and has said "The government and authorities concerned should try more to keep a good balance between the use of natural predators and of chemicals to control and eradicate weeds".

Recently, in a return to a natural ecosystem, modern technologies based on the development of the chemical industry, such as chemical fertilizers and pesticides including herbicides are tending to be

abandoned in agricultural production. However, the use of the limited area of the earth for the achievement of a satisfactory and sufficient supply of foods and materials to meet the world population explosion should be the most important and urgent world concern because it is expected by Dr. I. Yamamoto in Japan, that the world's population may reach about eight thousand million in forty years.

According to the introduction by William Inman, of UPI in Dallas, even Dr. Norman Borlaug, the famous Nobel Prize Winner who bred dwarf wheat and high yield crops, criticizes the anti-pesticide movement. He said the movement to ban chemicals is disgraceful. This problem has been grossly exaggerated. Pressing nations to restrict harmful but beneficial chemicals, he says, is like banning the car because of traffic hazards. Ecology activists reacted incredulously.

Another aspect of advanced weed technology, particularly the use of herbicides, is the impact on the socio-economic situation of farming enterprises. Input into advanced technologies and profits brought by the reduction of labour costs as well as by increased production of crops should be evaluated economically.

In this symposium, seven papers were invited from related professional fields. We do not think, however, that they satisfactorily cover all current aspects of symposium theme. For instance, the relation of weed plants to virus, bacteria, fungus and/or pest insects in the environment is of important significance, and should be given a multidisciplinary approach.

It is very gratifying and significant that a proper recognition and scientific understanding of the situation through the discussions in the symposium will indicate directions towards the solution of the complex environmental problems brought about by weeds themselves and their control technology.

Further, there is a current concept in which the control and utilization of weeds are moving in opposite directions. Dr. K. Ueki said at the water hyacinth meeting in Japan, "Specific biological characteristics of serious weeds such as vigorous growing habits, high adaptability against environmental conditions, high reproductive ability, and strong competitive power cause a weed problem in croplands as well as non-croplands; but these characteristics indicate the future potential of weedy plants for utilization as a biomass. A future strategy for weeds should comprise control and utilization". He also emphasized the

growing recognition of the co-existence of humankind and natural resources in the limited area of the globe.

Meanwhile, the symposium is appropriate as one of the objectives of the *National Weed Science Research Institute Project* of the Japan International Cooperation Agency (JICA), that has been implemented under the auspices of the Department of Agriculture, Ministry of Agriculture and Cooperatives, Thailand, since 1980. I would express our great thanks to JICA for partially sponsoring this symposium.

Finally, the contributions of seven speakers; Dr. H. Shibayama, Dr. M. Soerjani, Dr. S.K. De Datta, Dr. L.E. Bendixen, Dr. T. Smitinand, Dr. J. Harada and Dr. Y.L. Chen, who presented their own papers as well as of Dr. B.L. Mercado and Dr. K.U. Kim who shared the chairmanship of symposium with me are all acknowledged with sincere thanks.

Further, the Symposium Committee Members who cooperated in preparing the symposium, and Mrs. Yupin Kittipong and Miss. Lawan Chaiwiratnukul who helped in processing the editorial work of publication would be also thanked very much.

WEEDS AND THE ENVIRONMENT IN THE TROPICS
(Eds. K. NODA & B.L. MERCADO), pp. 5-31, 1986

BIOLOGY AND CONTROL OF *MIMOSA PIGRA* L.

H. SHIBAYAMA and P. KITTIPONG

*Chugoku National Agricultural Experiment Station, MAFF, Hiroshima, Japan,
and Botany and Weed Science Division, Department of Agriculture, MOAC,
Bangkok, Thailand.*

Abstract. *Mimosa pigra* L. has become a serious problem in not only Thailand but also other tropical countries. Regarding habitat, this weed is found at marginal and water-logged places in aquatic areas, abandoned fields, roadsides, etc.

Biological studies on the germination and establishment of this species were conducted in order to learn the causes of serious infestation. *M. pigra* seeds could germinate and establish only under upland conditions, but the seedlings already established became very tolerant against water-flooding, forming spongy tissues on stems and roots.

Low or alternating temperatures, burning by flame, scrubbing by sand and chemical treatments effectively induced seed germination. Scanning electron microscopic observations indicated that the strophiole of seeds might be an important point for water absorption in seed germination after breaking dormancy. Some growth regulators and herbicides were effective in inhibiting seed germination.

Aerial applications of herbicides for controlling *M. pigra* were conducted in northern Thailand. Results from the 1981 experiment indicated that glyphosate gave the best control of the species. Results from the 1982 experiment suggested that glyphosate, picloram, triclopyr and dicamba provided good control. Regrowth from the lower part of plants was found from 120 days after treatments when applied at low spray volumes. Deep flooding at the end of the rainy season provided complete control of regrowth.

INTRODUCTION

Mimosa pigra L. is a thorny and sensitive leguminous shrub species, which recently became one of the most serious weeds, especially in aquatic areas, of certain tropical countries. Although commonly referred to as "giant

mimosa", some scientists do not accept this name because there are several other local names such as "catclaw", "giant sensitive plant", "mai yarap yak" in Thai, etc. (Miller *et al.*, 1981; Ooi, 1982; Robert, 1982; Royal Irrigation Dept., 1982; Thammasara and Simagri., 1979). *M. pigra* was introduced to Thailand from Indonesia as a green manure crop in 1952 (Kittipong, 1980). Because of its high adaptability to Thai conditions, this plant has become a noxious weed along rivers, streams and swamp areas in the northern part of Thailand. The presence of *M. pigra* in aquatic areas has caused serious concern because of the disturbance of water flow in rivers and dam reservoirs and the decrease in the volume of reserved water. Further, *M. pigra* plants have invaded waste fields or roadsides along aquatic areas and have formed thick vegetation there. Owing to the shrubby, thorny characters of all stems, branches and petioles, *M. pigra* has made these lands useless.

Control measures involving both mechanical and hand methods have given poor results (Kittipong, 1980; Royal Irrigation Dept., 1982). Chemical control was first introduced in 1975 in an effort to improve efficiency. Foliar applications of several systemic and nonsystemic herbicides on *M. pigra* were evaluated under field conditions in Chiang Mai and Lamphun provinces. Systemic herbicides such as 2,4-D and 2,4,5-TP showed a higher efficacy in controlling *M. pigra* and other woody species than contact herbicides such as paraquat (Morton, 1966; Kittipong, 1980).

This paper deals with the investigation of certain biological characteristics of *M. pigra* (Shibayama *et al.*, 1983) as well as evaluation tests on promising herbicides in large scale aerial application.

DISTRIBUTION, HABITAT AND GROWTH

Distribution and Habitat

The distribution of *M. pigra* was investigated world-wide by Habeck, Harley and others, and was reported to include Texas, Central and South America, Central Africa, Southeast Asia, Northern Australia and other countries (Habeck, 1982; Harley, 1982; Miller *et al.*, 1981; Robert, 1982; Wiroatmodjo, 1982). Among these areas, Central and South America were considered to be the origin of this species. However, the countries most seriously infested with *M. pigra* are currently Thailand and Australia.

With regard to the distribution of *M. pigra* in Thailand, Royal Irrigation Dept. (1982), Nopompeth (1982), Robert (1982) and others have collected interesting information from local people and reported the distribution mainly on a provincial basis. The authors made visual surveys of distribution and habitat in northern Thailand from 1981 to 1983 (Fig. 1), because *M. pigra* became one of the most serious weeds,

Fig. 1. Distribution of *Mimosa pigra* in northern Thailand (black area).

especially in aquatic areas of northern Thailand, in recent years. With regard to habitat, the plants grow mainly in marginal areas along banks of canals, rivers and lakes, and also inhabit water-logged areas as seen

in Kiu Lom Dam and Doi Tao area of Bhumipol Dam Reservoirs (Plate 1). From greenhouse experiments mentioned in another chapter, it is certain that *M. pigra* can germinate from the soil even under upland conditions, where water levels are low during the dry season. As an example, the water level of Kiu Lom Dam Reservoir fluctuated about seven meters during one year in 1980, according to the data of the dam control office. After germination, however, young plants of *M. pigra* were able to grow up in flooded conditions, as water levels rose up month by month (plate 2).

M. pigra has infested many abandoned paddy fields and roadsides, especially in Chiang Mai province. This species shows high adaptability to upland conditions, though its infestation is not so great in other provinces. Abandoned fields were once inundated by water from the *Mimosa*-infested Ping River several years ago when there was heavy flooding around the city. As much of the river basin sand and soil from *Mimosa*-infested areas was widely used for road construction, *Mimosa* seeds were spread along these new roads. The wheels of cars running over roads also carried *Mimosa* seeds elsewhere along roads. Therefore, major *Mimosa* vegetation should be considered to be aquatic or aquatic-originated (Allen *et al.*, 1980). Vegetation under upland conditions as in road-sides, however, does not seem to be vigorous, because the authors could not find any dense *Mimosa* vegetation in upland fields or in mountain areas along these roads, except in wet places like ponds or streams in valleys. *Mimosa* plants do not seem to have the ability to invade in mountains and establish wide vegetation.

In farming areas, *Mimosa* plants usually grow densely only in and along aquatic places like streams, rivers or lakes, and they do not seem to establish in wet paddy fields. If farmers cultivate their arable lands and make weeding thoroughly, *M. pigra* plants do not seem to invade agricultural areas. In aquatic areas, it is interesting to observe that *M. pigra* could not infest deep water areas in rivers, lakes or reservoirs, and it is found only in shallow water river basins along banks and upstream areas in reservoirs. Only a few plants can be found near dam areas. These observations and our experiments show that *Mimosa* plants cannot germinate in deep, permanently water-logged areas. *Mimosa* seeds can germinate only in soils under upland conditions during the dry season as mentioned above. Even *M. pigra* vegetation already established is sometimes killed by deep flooding as seen at the Doi Tao area of Bhumipol Dam Reservoir.

A computer-analyzed colour picture of "Landsat" data on Kiu Lom Dam Reservoir area shows the usefulness of this method in surveying future changes of *M. pigra* vegetation by satellite. This survey and greenhouse experiments suggest the *M. pigra* has the potential to infest many other water areas of Thailand and other tropical countries in the future. However, this species cannot grow in aquatic areas where land is flooded throughout the year. Therefore, it is certain that *M. pigra* plants cannot infest downstream of the Chao Phraya River to Bangkok or the Mekong River to Vietnam, where the rivers are covered by deep water throughout the year.

Growth in Water-flooded Conditions

The growth and development of *Mimosa pigra*, including flowering and seed production, were extensively studied by Wanichanantakul *et al.*, (1979), Wara-Aswapati (1981), and others. However, its growth adaptability to flooded conditions has been barely investigated. Therefore, the anatomical structure of *M. pigra* roots from seedlings grown under upland and water-flooded conditions were investigated in order to discover the adaptability of *Mimosa* plants to both conditions.

Water-flooding provides the formation of spongy tissue from the periderm of *Mimosa* roots. As primary tissues, the epidermis and cortex are usually crushed by the secondary growth of the stele in seedlings from upland soil, but still exist at early stages of secondary growth in those from flooded conditions. Cork cell layers were found in the roots under flooded conditions, but were peeled off under upland conditions (Plates 3 and 4). Morphological differences of roots in both conditions may show physiological differences in adaptation of *Mimosa* roots to aquatic and upland conditions, though the mechanism of adaptation is not yet clear.

SEED GERMINATION AND ESTABLISHMENT

Effect of Soil Conditions

Mimosa pigra seeds could germinate well in all kinds of tested upland and paddy soils as seen in Table 1, although there were slight differences among them.

In sowing depth experiments, the hard seeds of *M. pigra* could swell by imbibing water, and germinate even in 20 cm depths of soil under

Table 1. Effects of soils* collected from different locations of Thailand on seed germination of *Mimosa pigra*.

upland conditions, though emerging up to the soil surface was possible only from 7 cm depth or less (Table 2). When seeds were placed deeper than 7 cm in the soil, they could germinate and grow, but the cotyledons could not reach the soil surface owing to the cessation of elongation and all of these underground seedlings died and later decayed. On the other hand, in water-flooded conditions seeds scarified with boiling hot water could swell by imbibing water when buried below the soil surface, but could not germinate at all, probably due to seed dormancy induced again by the anaerobic soil conditions. These swollen seeds, black in color, could germinate when dug out of flooded soil and put into the aerobic conditions.

These results, similar to Bhanthumnavin's (1977), show that *M. pigra* plants can probably grow on any kind of soil, but cannot emerge to the soil surface if seeds are placed deeper than 7 cm by cultivation or other practices.

Effect of Water Flooding

Flooding at depths of 0 to 20 cm over soil surface after *M. pigra* seeds were sown, allowed imbibition of water and consequently germination. Radicles and cotyledons developed to some extent. Cotyledons were green under flooded conditions and then seemed to be normal. Germinated seedlings, however, could not establish on the bottom of soil under flooded conditions, and their radicles could not elongate into the soil, curved upwards or wound in the water without anchoring to the soil. These seedlings were detached from the swollen seed coats, usually floated up to the water surface and finally died. In our observations, *M. pigra* plants which germinated under flooded water could not establish in the soil, even if they were marginally attached to the soil surface after floating up. Only a few seedlings survived in 0 cm flooding in this experiment, and their growth was very limited. As the results of three tests were almost identical, only the results of the first are shown in Fig. 2.

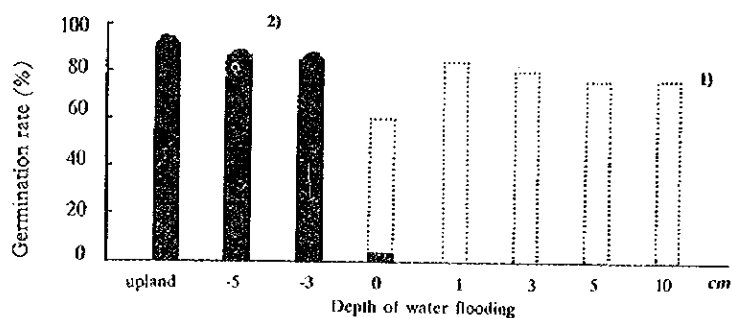

Fig. 2. Effects of water levels on seed germination of *Mimosa pigra*.

- 1) In a flooded condition (water level 0-10 cm), the majority of seeds decayed (0 cm) or floated up on the water surface and could not grow at all (1-10 cm) (dotted line), though some seeds could germinate.
- 2) Levels of -5 and -3 show the water level of 5 and 3 cm below the soil surface, respectively.

Fig. 3. Levels of water flooding for the seedling of *Mimosa pigra*.

- a: under cotyledon, d: under 3rd leaf,
- b: under 1st leaf, e: all leaves (complete flooding)
- c: under 2nd leaf,

The effects of water flooding on the growth and establishment of *M. pigra* seedlings are shown in Fig. 3 and Table 3. Complete flooding (all leaves, in Table 3) of *M. pigra* seedlings for 2 weeks (flooded at

cotyledon stage), 3 weeks (flooded at 1st leaf stage), 4 weeks (flooded at 2nd leaf stage), and 5 weeks (flooded at 3rd leaf stage) killed all plants in treated pots, but flooding for 2 weeks at 2nd leaf stage and for 1 and 3 weeks at 3rd leaf stage did not kill any seedlings, and regrowth began quickly when plants were returned to upland conditions. On the other hand, flooding for 3 months was found to kill even large vegetation in Doi Tao area of Bhumipol Dam Reservoir in 1981. In this experiment, tap water which is clearer than natural river or canal water, was used as the flooding water. Natural water contains many soil particles which reduce the light intensity in water. Therefore, completely submerged plants in this experiment could probably survive more days than plants flooded by river water in natural conditions. Flooding below the cotyledon or flooding below other leaves did not kill *Mimosa* seedlings, although root development was considerably inhibited in these seedlings as shown in a top-root ratio of below 4.7 in the untreated control plants (Table 3).

Table 3. Effect of water-flooding on growth of seedlings of *Mimosa pigra*.

Leaf stage of <i>Mimosa</i> at flooding	Depth of flooding*	Number of survived plants	Fresh weight per plant	Top-root ratio (T = 1)
		%	%	
Cotyledon	All leaves (2 weeks)	0	0	0
	Under cotyledon	85	76	3.6
1st leaf	All leaves (3 weeks)	0	0	0
	Under 1st leaf	31	60	2.6
	Under cotyledon	98	39	3.0
2nd leaf	All leaves (4 weeks)	0	0	0
	All leaves (2 weeks)	86	66	3.5
	Under 2nd leaf	88	42	2.2
	Under 1st leaf	92	57	2.9
	Under cotyledon	89	48	3.8
3rd leaf	All leaves (5 weeks)	0	0	0
	All leaves (3 weeks)	46	20	1.9
	All leaves (1 week)	95	107	3.9
	Under 3rd leaf	80	29	1.7
	Under 2nd leaf	86	75	3.1
	Under 1st leaf	96	67	4.0
Untreated Control		100	100	4.7

Remark: * Shown in Fig. 3

From these experiments, it can be concluded that, although non-dormant *M. pigra* seeds can germinate even in water-flooded conditions, they cannot grow and establish because germinated seedlings will float up to the water surface without anchoring to the soil and will later die. *M. pigra* seedlings, which germinate on the soil where water is below saturation, can establish and withstand water-flooding provided upper leaves remain above the water surface. Even complete flooding in the rainy season will take a few weeks to kill the submerged seedlings of *M. pigra*.

Effects of Temperature and Light

With regard to constant temperature experiments, hot water was effective for breaking the dormancy of *Mimosa* seeds (Premasthira, 1981) by 1 sec to 1 week treatments and the germination rate increased as temperatures were raised to 98°C (Figs. 4 and 5).

In each temperature, the germination rates were tended to increase and then decrease as the treatment time became longer (Fig. 4).

Fig. 4. Effect of periods of constant temperature treatment by hot water bath on germination of old seeds of *Mimosa pigra*.

Experiment was conducted in August to October, 1982. Seeds were moved to room temperature after treatment. Old seeds were collected in 1981.

s : second, m : minute, h : hour, d : day, w : week

Fig. 5. Effects of constant temperatures on maximum germination rate of old seeds of *Mimosa pigra*. Experiment was conducted in August to October, 1982. Seeds were moved to room temperature after treatment. Old seeds were collected in 1981.

One week treatment of low temperatures of 5 and 10°C was very effective in breaking the dormancy of old seeds collected in 1981, but as temperatures were raised the germination rate decreased (Fig. 5). With regard to alternating temperature experiments, 10 to 20°C differences between day and night temperatures for 1 or 2 weeks gave the high rates of breaking dormancy. At day temperatures of 30 or 35°C, a 15°C difference was necessary to get high germination rates, but at day temperatures of 25°C or less, even 10°C difference was enough to get high germination rates. Moreover, in the test of 1982, old seeds collected in 1981 showed higher germination rates than new seeds collected in 1982 (Fig. 6).

Fig. 6. Effects of alternating temperatures on germination of old and new seeds of *Mimosa pigra*.

Experiment was conducted in August to October, 1982. Temperatures were treated one or two weeks (day temperature 25°C only), and then seeds were moved to room temperature. Old and new seeds were collected in 1981 and 1982, respectively. Day (light) : 6.00 a.m. - 6.00 p.m., Night (dark) : 6.00 p.m. - 6.00 a.m. RT : room temperature.

Under natural conditions, seeds of *M. pigra* seem to germinate more as they become the older. In our experiments, old seeds which had been stored for more than one year after collecting showed better germination rates than new seeds. Bhanthumnavin (1977) got better germination rates than ours when she used four or five years old *Mimosa* seeds, and reported that 64% of such seeds germinated when incubated at 32°C room temperature for 10 days. These results suggest that the germination rate of *M. pigra* seeds increases year by year after ripening and shedding in the soil surface or at the bottom of water in aquatic areas.

Seed germination of *M. pigra* was enhanced strikingly when low temperatures such as 5 to 20°C were used in constant or alternating temperatures. According to the data of the Meteorological Department, Thailand (1981), mean maximum and minimum temperatures during the winter season in Chiang Mai are around 29 and 15°C, respectively. Therefore, one of the reasons for *Mimosa*'s serious invasion in northern Thailand is considered to be the low temperatures in this region.

Light-dark (day-night) and continuous dark conditions did not show any differences in seed germination (Fig. 7). Seeds stored in water germinated more than those in an air dry condition under alternating or constant temperatures.

Fig. 7. Effects of light and storage conditions on seed germination of *Mimosa pigra*.

Experiment was conducted in September to October, 1982, at alternating temperatures of 30-20 or 30-15 C. Old and new seeds were collected in 1981 and 1982, respectively.

Light: day time (6.00 a.m. - 6.00 p.m.) only and night time was dark.

Dark: whole day dark

Wet: stored in water

Dry: stored in an air-dry condition

Effects of Other Factors

Seeds collected in 1982 were subjected to burning by flame and scrubbing with sand paper to confirm that *Mimosa* seeds germinate in large numbers after vegetation along roadsides is burned or after river sand containing numerous *Mimosa* seeds is used for road construction.

Burning was effective for breaking the dormancy of new seeds of *M. pigra* (Fig. 8), but flaming of more than 10 or 20 seconds was usually too long because almost all burned seeds were popped and did not germinate at all. Scrubbing seeds with sand paper was also effective for

Fig. 8. Effects of burning by flame, scrubbing by sand paper, conc. H₂SO₄ and conc. HCl on germination of new seeds of *Mimosa pigra*.

Experiment was conducted in 1982. New seeds were collected in the same year.

germination (Fig. 8). However, when seeds were mixed with sand in a small bag and scrubbed strongly by hand or beaten several times on the ground, germination was not enhanced at all. Burning *M. pigra* plants and agitating sand or soil mixed with seeds were largely confirmed experimentally to induce the awakening of *M. pigra* seeds from dormancy, although the mixing of seeds with sand for scrubbing by hand or beating on the ground did not give any effect.

To break the dormancy of new seeds, treatments with conc. H₂SO₄ and conc. HCl for 0.5 to 10 min and with organic chemicals such as acetone (99.5% and 98%), ethyl alcohol (100%, 99.8% and 70%), ethyl ether (99% and 95%), benzene (100%), xylene (96%), toluene (97.5%) and chloroform (99%) for 10 min, 1 hr and 1 day were made. A conc. H₂SO₄ treatment for 0.5 to 10 min was very effective, but

conc. HCl did not break seed dormancy (Fig. 8). Among the organic solvents, only 99.5% acetone (Analytical grade) was effective in awakening dormant *Mimosa* seeds, no other treatments showing any effect (Fig. 9).

Fig. 9. Effects of organic chemicals on seed germination of *Mimosa pigra*.

Experiments were conducted three times in November (I), December(II), of 1982 and February(III) of 1983. New seeds collected in 1982 were used.

(A) were "analytical grade", others were "extra pure grade"

Scanning Electron Microscopic Observations on Seed Coats

Regarding environmental or artificial factors which affect the seed germination of *M. pigra*, it was considered that seed coat dormancy was broken by these factors (Bhantumnavin, 1977). On the other hand, changes of water permeability of the strophiole or hilum area of the seed (Fig. 10) was found to be important for water imbibition and then for dormancy breaking of some leguminous seeds, and most parts of the seed coat were found not to be the primary site of water entry (Egley, 1979).

Fig. 10. Effect of vaseline coating on seed germination of *Mimosa pigra*.

New seeds collected in 1981 were used for treatments except "alternating temperature" in which old seeds collected in 1981 were used. Vaseline was coated at black portions of the above-figured seed. Left end of seed was the top and right one was the base in the above figure. Experiment was conducted in 1982.

This work was conducted to investigate what part of *Mimosa pigra* seeds would be affected by dormancy breaking factors to result in an increase of seed coat permeability. The seed coat of *M. pigra* was affected with various treatments for breaking dormancy as mentioned previously, and many of seeds began to imbibe, swell and germinate. However, when the top, middle and base ends of each seed (Fig. 10) were coated with vaseline after treatments, these coated seeds revealed differences in water absorption and germination.

As seen in Fig. 10, seeds treated with boiling hot water, alternating temperatures, flame burning and acetone had little or no germination when the base end was coated with vaseline, but those in which the middle or top ends were coated, germinated very well as did uncoated seeds. Seeds treated with conc. H₂SO₄ and sand scrubbing could germinate at about the same or half the rate of uncoated seeds, even when the base ends of the seeds were coated with vaseline. The

strophiole, hilum and micropyle tissues are at the base end of seed in this experiment. Boiling hot water, alternating temperatures, flame burning and acetone, which induced water imbibition through the base end of the seed, would be mainly effective in changing the water permeability of these tissues (Egley, 1979). However, these treatments seemed to be ineffective in enhancing water imbibition through other parts of the seed coat. On the other hand, conc. H_2SO_4 and sand scrubbing treatments seemed to change water permeability in all parts of the seed coat (Fig. 10).

Thus, scanning electron microscopic observations on seed coats of *Mimosa pigra* were made. Boiling and low temperature treatments produced little change at the top and middle parts of *Mimosa* seeds compared with untreated seeds (Plate 5). However, the strophioles at the base end which seemed to be site of water entry to break dormancy (Plate 6, 7) were frequently swollen and cracked after these treatments. No. external morphological change was found at the hilum or micropyle. On the other hand, a conc. H_2SO_4 treatment caused severe damage to the outer layer of the seed coat (Plate 8) in addition to swelling and cracks in the strophioles. This damage would be the reason for the differences in water imbibition after various dormancy breaking treatments and vaseline coating.

In natural conditions, it seems that the dormancy of *M. pigra* seeds will be broken mainly by factors which produce swelling and cracks in the strophiole, although Egley (1979) reported that the hilum was the main site of water permeability for other leguminous species.

CHEMICAL CONTROL BY AERIAL SPRAYING

Materials and Methods

The test site of chemical control by aerial spraying (Plate 9) was located in Kiu Lom Reservoir, Lampang province 642 kilometers north of Bangkok whose elevation is 241 meters above sea level. Average annual rainfall within the area is 1,079 mm. The maximum and minimum temperatures are approximately 32.6°C and 20.2°C respectively. Sunshine averages approximately 8.0 hours per day.

Water depth in the test area reaches a maximum of 3.5-4.0 meters in December or January but the reservoir is completely dry in May and

remains in this state for about 4 months before the monsoon flooding begins.

Herbicides used in 1981 were glyphosate 41% [N-(phosphonomethyl) glycine] at 12.5 and 25.0 liters (product)/ha and fosamine 42% [ethyl hydrogen (aminocarbonyl) phosphonate] at 18.75 and 31.25 liters (product)/ha with 125, 250 and 375 liters of spray solution/ha. In 1982, test herbicides included glyphosate, picloram 49.8% (4-amino-3,5,6-trichloropicolinic acid) and triclopyr 48% [(3,5,6-trichloro-2-pyridinyl) oxy] acetic acid at 6.25 and 12.5 liters (product)/ha and dicamba 40.6% (3,6-dichloro-o-anisic acid) at 12.5 and 25.0 liters (product)/ha in 62.5 and 125 liters/ha of spray volume.

Age of the natural growth of *M. pigra* within the test area was estimated to be 4-5 years old with heights ranging mostly from 4.0-4.5 meters.

Spraying was conducted with a "Miller 305" helicopter travelling at 20 knots equipped with a 160 liter spray tank and 59 nozzles on a 9.7 meter spray boom which covered 10 meters each swath. All applications were made near plant-top level. Time of application was between 8 A.M. to 4 P.M. in 1981 and between 8.00-11.00 A.M. in 1982.

A randomized block design with two replications was used in this test. Plot size measured 20 x 320 meters or 6,400 square meters. Data were collected from the middle of each plot. Visual observations were made at 30 day intervals using a 0-10 point scale throughout the 12 months study.

Results and Discussion

Data collected in the 1981 wet season are summarized in Table 4. Results show that within the first month after application of fosamine and glyphosate on a natural growth of mimosa in Kiu Lom reservoir more than 90 percent of the giant mimosa was defoliated. Glyphosate showed more effect than fosamine.

At the end of the first 30 days after treatment, glyphosate at 12.5, 25.0 liters (product)/ha in 125, 250 and 375 liters of spray solution provided approximately 90-100 percent defoliation when compared with fosamine at 18.75 and 31.25 liters (product)/ha in the same amount of spraying volume which resulted in 70 to 90 percent defoliation.

Table 4. Performance of glyphosate and fosamine for *Mimosa pigra* control by aerial application at Kiu Lom reservoir, Lampang, Thailand, 1981.

Treatments	Rate Lts (mat)/ha	Spray Vol. Lts/ha	Performance (d.a.t.)					
			30	100	120	180	240	365
fosamine	18.75	375	7.0	4.0	2.0	0	0	0
fosamine	31.25	375	9.0	6.0	5.0	3.0	0	0
glyphosate	12.5	375	10.0	9.5	10.0	10.0	10.0	10.0
glyphosate	25.0	375	10.0	10.0	10.0	10.0	10.0	10.0
glyphosate	12.5	125	10.0	9.5	9.5	9.5	9.0	9.0
glyphosate	25.0	125	10.0	10.0	10.0	10.0	10.0	10.0
fosamine	18.75	125	7.0	4.0	3.0	0	0	0
fosamine	31.25	125	8.0	6.0	4.0	3.0	2.0	0
fosamine	18.75	250	7.0	4.0	2.0	0	0	0
fosamine	31.25	250	8.0	6.0	5.0	3.0	0	0
glyphosate	12.5	250	9.0	9.5	7.5	5.0	4.0	4.0
glyphosate	25.0	250	10.0	10.0	8.0	7.0	4.0	4.0

Remarks: Figures are from visual observation using a 0 to 10 scale with 10 being 100% defoliation

d.a.t. = days after treatment

At 100 days after treatment, the killing action of glyphosate appeared to be at a satisfactory level with complete defoliation noted on plants treated at both rates at all three levels of spraying solutions. The killing action of fosamine declined with time.

Regrowth from stems was observed on plants treated with fosamine. The chemical apparently was not mobile within the plants because the tops of the plants were defoliated but the lower branches remained green. Similar results were observed at 120 days following application of fosamine.

At 180 days following treatment continued regrowth was found on fosamine treatments with the lower rate showing almost complete regrowth.

Application of glyphosate at both low and high rates with 125 and 375 liters of water/ha provided satisfactory results but application of the same concentrations in 250 liters of water showed approximately 50 and 30 percent regrowth. Similar results were recorded at 240 days after treatment.

At the final checking, or at 365 days after chemical application, results showed that glyphosate at 12.5 and 25.0 liters (product)/ha in 125 and 375 liters of spray volume gave 90-100 percent control of *Mimosa* plants but application of the same rates in 250 liter/ha of spraying solution resulted in 60 percent regrowth. All spray treatments with fosamine showed complete regrowth one year after spraying was done.

Results from the 1982 dry season are listed in Table 5. Data indicate that herbicides such as dicamba, glyphosate, picloram and triclopyr showed fast top killing action within 30 days after application under the dry condition of Kiu Lom area. Complete defoliation of the leaves and complete killing of the top plant parts were noted 60 days after treatment. Visual observations indicated no differences among treatments during the 60 days after spraying.

Table 5. Performance of dicamba, glyphosate, picloram and triclopyr for *Mimosa pigra* control by aerial application at Kiu Lom reservoir, Lampang, Thailand, 1982.

Treatments	Rate Lts (mat)/Rai	Spray Vol. Lts/ha	Performance (d.a.t.)				
			60	120	180	240	365
dicamba	12.5	62.5	10.0	9.5	8.0	10.0	10.0
dicamba	12.5	125.0	10.0	10.0	10.0	10.0	10.0

triclopyr	12.5	62.5	10.0	9.5	7.5	10.0	10.0
triclopyr	12.5	125.0	10.0	9.5	8.5	10.0	10.0

Remarks: see Table 4

Records at 120 days after application showed slight differences in the degree of efficacy for all four tested compounds compared to 60 days following spraying.

Observations made at 180 days after application indicated that dicamba at 12.5 and 25.0 liters (product)/ha and glyphosate at 6.25 and 12.5 liters (product)/ha in 125 liters of spraying volume gave complete control similar to the first 30 day checking but application of both herbicides at the same rates using 62.5 liters spray volume gave less control with time and regrowth was observed on the lower parts of the stems. Regrowth was also recorded from plots treated with picloram and triclopyr at 6.25 and 12.5 liters (product)/ha in 62.5 and 125 liters of spraying solution.

A better degree of control was detected from all treatments at 240 days after application and absolute control was obtained after 240 days and up to 360 days after application due to the increasing water level in the reservoir at the end of the rainy season.

Visible toxicity to near-by vegetation indicated that glyphosate was highly selective on many broadleaf species other than grasses. Dicamba on the other hand showed high selectivity for grasses while the rest of the tested compounds did not show any selectivity for grasses or broadleaf plants.

Fosamine and glyphosate showed similar defoliation action on natural growth of *Mimosa* plants at 30 days after application, but the effectiveness of glyphosate increased with time and a high water level in the Kiu Lom reservoir. This suggests that high moisture conditions speeded up glyphosate activities (Jordan, 1977). The increase in glyphosate action might relate to its classification as an ambimobile rather than a specific phloem-mobile herbicide (Dewey and Appleby, 1983).

The visible toxicity obtained from application of fosamine indicated that it did not translocate within the plant and its activities decreased with time. Good coverage of all the leaves and green plant parts is important for effectiveness of fosamine. A spray volume less than 200 liters/ha is not sufficient for fosamine to control plants taller than 1.5 m in height (Nichuss, 1974).

Time of application is also critical for aerial control of *M. pigra*. Treatments applied in the morning allowed plants to absorb more chemical than when applied later in the afternoon of the same day.

Data collected from the dry season experiment indicated that foliar application under dry conditions stimulated absorption and translocation of all four tested compounds. Deep penetration through both apoplast and symplast portions of the plants by dicamba and glyphosate resulted in better control of *M. pigra* when compared with picloram and triclopyr in the first 6 months. The minimum spraying volume for aerial control of natural growth plants is 125 liters/ha or more (Niehuss, 1974). Suitable spraying time for best control is from morning up until noon.

The results suggest that *Mimosa pigra* can be controlled if the proper herbicides, spray volume and timing are used (plates 10, 11, 12, 13 and 14). Economics of using the aerial spray procedure have not yet been worked out.

CONCLUSION

With regard to the *Mimosa pigra* problem in not only Thailand but also other countries, there is the danger of future spreading to many other aquatic areas of tropical countries because of the prolific ability of *M. pigra*. This species, however, may be incapable of infesting the main streams of large rivers such as the Chao Phraya river and the Mekong river because *M. pigra* seeds cannot germinate and establish at heavily water-logged places. Further, this species cannot infest natural forest areas in mountains as well as agricultural lands under cultivation.

The management program of *Mimosa pigra* in aquatic areas and their surroundings should be designed based on the following ideas.

1) Application of herbicides such as glyphosate, dicamba, triclopyr and picloram is certainly effective, but the complete eradication of this weed from specific areas by herbicide application alone is not preferable because it would require a large amount of chemicals with the potential of producing adverse effects on the environment.

2) Mechanical and/or manual procedures for eradicating this species are very tedious and expensive because of its stout growth with many acute spines on main and branched stems.

3) This program should not be terminated in a short time, because *Mimosa pigra* is likely to create regrowth and reinfestation through seeds buried in the soil even when the major part of the vegetation is

controlled. Further, it will take a long time to practice biological control by insects and/or plant pathogens in the future.

4) Integrated control of *Mimosa pigra* should be practised by means of combining chemical control, mechanical control, hand weeding, water level management, biological control, and so on.

5) The utilization of *Mimosa pigra* should be very significant for its long term management. Success, however, depends on various multiple, longterm studies in the future.

WEEDS AND THE ENVIRONMENT IN THE TROPICS
(Eds. K. NODA & B.L. MERCADO), pp. 33-49, 1986

ENVIRONMENTAL CONSIDERATIONS IN THE NOVEL APPROACH OF AQUATIC VEGETATION MANAGEMENT

Mohamad SOERJANI

*Centre for Studies of Human Resources and the Environment, University of Indonesia,
Jakarta, Indonesia*

Abstract. The growing environmental awareness since the 1960's refers among others to the improvement of measurement techniques, and the rapid increase of the knowledge of dose-response relations. There is also an increasing concern of the fact related to our finite world, the increasing pressure of the human population and the continuous changes of life-style on the limited resources on earth. This creates various problems due to the increasing production of wastes and the increasing disorders in the system in which we live. One of the important impacts of the increased activities of man on aquatic system is the unwanted growth of aquatic vegetation. Under certain tropical conditions this may facilitate an increasing complexity of problems in a proper water resources management. Therefore, an appropriate approach should be developed for an environmentally sound aquatic vegetation management, so that side effects and negative impacts can be mitigated, while the problems are viewed from an optimistic dimension, and considered as opportunities.

Some of the common practices in aquatic vegetation management and some of the shortcomings will be presented and the novel approaches of aquatic vegetation management with environmental considerations will be discussed. These among others considering aquatic vegetation as a potential resource, in which utilization of its biomass will have twofold benefits, namely to get a pay-off from getting rid of the aquatic biomass. There are various opportunities to utilize aquatic vegetation for the direct and indirect benefits for men. In the biological control method of aquatic vegetation the use of herbivorous fauna ending it up beneficially for men, e.g. fish, or competing it with other more beneficial vegetation, e.g. *Ipomoea aquatica* and other hydroponic plant species. This is better than ending in the trophic pyramids with a top level fauna unknown in its

function in the system. Another novel approach is the use of slow-released formulations of herbicides with polyvinyls, alginates, rubbers, etc. to minimize the potential drift which may pollute the aquatic system. There are, of course, other environmental risks in the development of these methods, among others the potential development of resistance, which will be discussed as potential risks to be considered. It is hoped that with an appropriate environmental consideration the aquatic vegetation management could be implemented properly, that we may achieve a better quality of life in a better and healthy environment.

INTRODUCTION

Since 1960's there have been a growing awareness that the biosphere is anticipating environmental crises. This culminated in 1972 when the Stockholm Declaration on the Human Environment was declared, which gave an impetus to the development of "modern" environmental studies and management. The growing awareness refers also among others to the improvement of measurement techniques, in which *e.g.* trace elements or pollutants can be accurately measured or detected. This has been accompanied with the rapid increase of our knowledge in dose-response relations. Any component in our system is related, interacted, and dependent with other components.

There is only one world, while due to its rapid increase, the human population creates pressures not only by number, but also by the changes in human life-styles. Consequently the study of the human environment must be a complicated one. One aspect of study in environmental science is that often there is no simple answer to any given problem. There is always controversy as an integral part of the study. Therefore, environmental consideration in any effort to manage a system will result in something compromistic in nature, with only optimal results, never something maximal for one and risks for the rests.

This paper is an overview of man's activities that may create impacts on the aquatic environment, particularly in the abundant growth of aquatic vegetation. This vegetation may be considered as an aquatic weed that creates nuisance to the optimal function of an aquatic resource. Finally, the paper will deal with efforts to manage the problem appropriately, with sound environmental consideration, and with an optimal result for all concerned.

AN INCREASING ACTIVITY WITH AN INCREASING RISK

With an increasing number of population and the increasing trend of needs due to continuous changes in life style, humans tend to get more from the limited resources. This is made possible with the continuous development of technology, which may facilitate more products for human beings, but in turn, may create more wastes and more pollutants. Therefore, there is always an increasing disorder and increasing risk in human life (Fig. 1).

Since generally speaking there is always a decreasing quality of our environment, there is a decreasing quality of life. Therefore, there is a need to manage our environment appropriately as shown in Fig. 2, in order to maintain the quality of the environment, by which to maintain the quality of life.

AQUATIC RESOURCE AND AQUATIC VEGETATION

Water is one of the most vital resources to sustain life and the activities of

Fig. 1. The increasing activities of man (through technology) will produce product(P) to consume(C) which create waste(W), industrial waste (W_i) and consumption waste (W_c). These create direct(di) and indirect(idi) (through physical and biotic components) impacts to man.

Fig. 2. A. As product(P) increases the quality of life(QOL) is decreasing, therefore: B. Environmental management(M) is needed, that P is still increasing while QOL is maintained (modified from Beale, 1980)

man as well as other living organisms. It dissolves and transports nutrient from the soil into the bodies of plants and animals, dissolves and dilutes many of the wastes, serves as a raw material in all phases of metabolisms, and is major factor in the world climate and weather system (Miller Jr. 1979). Water is not only vital but also unusual because of its physical and chemical characteristics. In the ecosystem, water has a unique hydrological system and with a complicated energy relations in its various stages and phases of existence.

The aquatic system includes distinct parts of the environment such as rivers, streams, lakes, estuaries, and coastal and deep ocean waters (Duke, 1977). It is clear that, by definition, man's interactions with water will cover a vast and complicated area, in addition, these systems represent almost all groups of life-forms. However, man's use of water is dominated by only a small fraction of water called fresh water or sweet water (approximately 3% out of the total water volume of $135.10^{10} m^3$). Therefore, man's impact on water is mainly accumulated in fresh water system, *c.g.* rivers, streams, ponds, and lakes. The human needs of water is shown in Table 1.

Those usages of water for irrigation, industry, and domestic purposes determine the impact of man's activities on the water quality, namely the kind and amount of wastes and pollutants dumped into the water. This creates pollution and eutrophication that in turn changes the life-forms in the aquatic habitat.

The first to change is the aquatic flora, the macrophytes as well as the microphytes, which will become abundant in a eutrophied system. Under a large majority of lake conditions, the most important factors causing the abundant growth of aquatic macrophytes are phosphorous and nitrogen. The community will be occupied mainly by dominant species or mixtures of several species. The most important ten aquatic weed species in the world are shown in Table 2.

It has to be noted, however, that with the increasing activities of man, there is a considerable change in the composition of aquatic vegetation throughout the world from time to time. In most cases, such as in the case of water hyacinth (*Eichhornia crassipes*) and molesting salvinia (*Salvinia molesta*), aquatic weed problems arises from exotic species. The aliens seem to reproduce faster and spread more vigorously than in their native ranges, particularly if in their new habitat, resources are not fully utilized by native species (Ikusima, 1983), also if natural enemies in the new area have not yet established in their full balance.

It has to be noted that luxuriant submerged and floating vegetation is not very productive when compared to the marginal or emergent vegetation. The dry weight per unit area of submerged and floating vegetation is low compared with that to communities such as marsh or reed swamps (Sculthorpe in Gaudet, 1974). This is also due to the fact that plants under water will have less availability of oxygen and carbon dioxide from the atmosphere (Sastroutomo, 1985). In a shallow region to a depth of about one meter, there will be a potentially high

productivity of emergent macrophytes that utilize resources from the aqueous sediment and the aquatic habitats.

THE ROLE OF AQUATIC VEGETATION

Aquatic vegetation is a primary producer that sustains other groups of living organisms. It provides direct food for herbivorous organisms and detritus for detritivorous and sapotrophic organisms. It may serve as the habitat for organisms living in the phyllosphere, or provide shelter, hiding and breeding place for other living organisms. Some other role of aquatic macrophytes in the system are : as soil stabilizers; in nutrient cycling, as nutrient pump from the soil, and in water purifications; as a source of food for terrestrial organisms, e.g. bird and man. Sastroutomo (1985) listed 20 aquatic plant species that are eaten, partly or wholly, by birds, among others those considered as important weed species, e.g. *Ceratophyllum* spp., *Myriophyllum* spp., *Polygonum* spp., *Sagittaria* spp., and *Scirpus* spp.

Further on the list of aquatic plants edible to men is as shown in Table 3.

Table 3. Aquatic plants edible to man (Sastroutomo, 1985).

No.	Species	Part(s) used	Use
1.	<i>Acorus calamus</i>	Under ground parts	Medicinal
2.	<i>Butomus umbellatus</i>	Under ground parts	Medicinal
3.	<i>Glyceria fluitans</i>	Seeds	Food
4.	<i>Phragmites communis</i>	Under ground parts	Food
5.	<i>Rorippa nasturtium-aquaticum</i>	Shoots	Food
6.	<i>Sagittaria sagittifolia</i>	Under ground parts	Food
7.	<i>Typha</i> spp.	Pollen, under ground parts	Food
8.	<i>Zizania latifolia</i>	Under ground parts, leaves	Medicinal
9.	<i>Nelumbo nucifera</i>	Under ground parts, seeds	Food
10.	<i>Ipomoea aquatica</i>	Leaves	Food
11.	<i>Brasenia</i> spp.	Young leaves	Food
12.	<i>Limncharis flava</i>	Leaves	Food
13.	<i>Eichhornia crassipes</i>	Young leaves, flower buds	Food

For other purposes aquatic plant species may also have other functions, e.g. as cattle feed, mulch, green manure, pulp, handicraft, religious and traditional ceremonies, and various source of chemicals. It also serves as ornamentals and add to the beauty and serenity of an aquatic landscape.

The role in causing nuisance to man or decreasing the value of a system is normally due to its abundant growth, so that the plant is in excessive population. This may include loss of water storage, as agricultural and public hazards, as habitat for disease agents and their vectors, etc.

The role of aquatic plants is very much determined by the activities of man affecting the aquatic system as shown in Fig. 3.

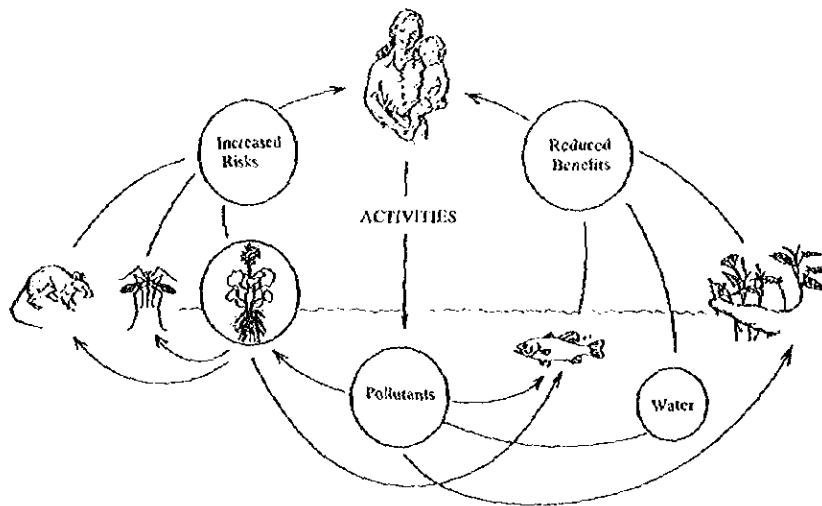

Fig. 3. The activities of man that affect an aquatic system.

The pollutant may enrich water that stimulates excessive growth of aquatic weeds. It may also contain hazardous pollutant that may enter the biotic components, e.g. vegetable, or fish that may finally end up to human beings.

AQUATIC VEGETATION MANAGEMENT WITH ENVIRONMENTAL CONSIDERATIONS

The above chapters give a general idea of the place and role of aquatic plants in the holistic system of life and nature, in particular in the aquatic system. Those are the general basis in the development of control measures if environmental quality is taken into serious consideration.

Aquatic weed management is part of aquatic vegetation management which is again part of the whole aquatic resource management, which must be aimed at the development of an amenity fresh water system. This refers to the social and environmental function of a water resource. The system must be developed based on social and environmental agreeableness, social pleasures, or as agreeable pursuits in general. The amenity fresh water system should be defined as a water system with harmonious environmental, economic, recreational, spiritual, and aesthetic values. Priority of the criteria must be in the first instance referred to the social and environmental function of a water body. There are benefits from a water body which are easy to value, e.g. fish production, drinking water supplies, rice field irrigation, or industrial water supplies. In other cases, however, valuation is not easily accomplished, especially for non-marketable items, such as the environmental quality, visual attractiveness, and other spiritual values. Therefore, in general, the strategy must develop a low cost and low maintenance system, relevant to the present day escalating cost of living.

The common model to develop an amenity fresh water system is shown in Fig. 4 (Soerjani 1983).

The following are steps to be considered as a general approach in an appropriate and environmentally sound aquatic weed management.

5.1 Terrestrial and Marginal Plant Gallery

As shown in Fig. 4 the activities of man will produce wastes (W_1) which may be recycled, reutilized, or screened by gallery of plants in the marginal or on the bank of a water body. By so doing a resource R_1 , e.g. timber, vegetable, flower, and fruits can be harvested. It has only to be taken into consideration that the waste may contain hazardous chemicals that may also pollute or contaminate the products edible to animals or man.

Fig. 4. A model of man's activities(A) that create wastes(W) which can be converted through appropriate management to become useful resources(R) in an amenity fresh water system(Soerjani, 1983).

5.2 Hydroponic or Aquaculture Plants

To compete for space, and therefore also to compete for nutrient and probably also light, hydroponic or aquaculture plants can be planted in a bamboo raft or something similar to it. The plants selected must have some beneficial values to humans, e.g. floating rice or edible *Ipomoea*. However, again it has to be taken into consideration if there are certain hazardous chemicals contaminating the products.

5.3 Fish Management

Fish management may control or utilize the weed biomass, by the introduction of an appropriate fish, particularly grass carp (*Ctenopharyngodon idella* Val.) which will directly consume the macrophytes. The fish is edible and serves as a good source of protein (R3).

In the fresh water food web, some other fish can also be cultured (Fig. 5). The introduction of silver carp (*Hypophthalmichthys molitrix* Val.) which will consume plankton is one of the appropriate combinations with grass carp. Grass carp will digest only part of the macrophytes

Fig. 5. Primary production as a direct source of fish production or through a food chain in a fresh water system (after Stengel, 1976).

- (1) silver carp = *Hypophthalmichthys molitrix* Val.
- (2) tilapia = *Sarotherodon mossambicus* (Peters)
- (3) tambakan = *Helostoma temminckii* C.V.

- (6) grass carp = *Ctenophryngodon idella* Val.

consumed, and the release of the partly digested food will stimulate the growth of plankton, which in turn will be consumed by silver carp.

The use of herbivorous fish to manage weed population has another positive aspect, namely to provide man with certain beneficial resource. The use of fish can also be classified as an appropriate biological control method, since the addition of a component in the trophic level has ended up to something clear in its function in the food web or in the entire web of life. Fig. 6 shows that biological control method of water hyacinth using insect, e.g. water hyacinth weevil (*Neochetina eichhorniae* Warner) will end up at something unknown to our present knowledge (A). Our experience in Indonesia with the weevil showed that the insect has two

other hosts, namely the edible canna (*Canna edulis*) and ginger (*Zingiber* spp.) both are secondary economic crops in Indonesia, while the introduction of grass carp *Ctenopharyngodon idella* Val.) may end up beneficially to man (B). It has to be noted, however that the top component in the trophic structure does not necessarily benefit man, but something, for sure, compatible in the entire good and healthy quality of our environment.

Fig. 6. Schematic situation of the trophic structure in a biological control of water hyacinth. (Soerjani, 1985).

A. With the weevil; B. With grass carp

5.4 Utilization of the Aquatic Weeds

A further option is to harvest the weed biomass and utilize it as a resource (R4) for various purposes (Soerjani, 1982; 1983; Wolverton and McDonald, 1979a). Most fresh water weeds can be directly consumed by pigs and ducks, or other livestock, e.g. cattle (Kashem *et al.*, 1983), chicken and rabbit after certain processes. It can be utilized as supplementary feed for the pen culture of carp and tilapia (Edward, 1980; Hiranwat, 1983). Other uses of fresh water weeds are for biogas production, fuel, fertilizer, soil additives or mulch, mushroom culture, paints (Vedanayagam *et al.*, 1983) the reduction of water pollutants from pulp/paper mills, tanneries (Haider *et al.*, 1983), rubber and oil palm industries (John, 1983) and human waste (Wolverton and McDonald, 1979 b). Water hyacinth and some other aquatic plants are harvested to

produce handicrafts, e.g. shoes, bags, trays, carpets, vase, ropes, decorations, and picture frames. The most promising use of water hyacinth and *S. grossus* is for pulp, carton and paper production. In various parts of South and South-east Asia cartons from water hyacinth manufactured in some rural areas by an appropriately simple technology have become a promising marketable product. Efforts are still continuing to produce particle boards and cement boards from water hyacinth biomass.

5.5 The Use of Herbicides

In special cases when all the efforts do not work well due to certain constraints, the plant population or community may temporarily have to be suppressed by known control methods, i.e. mechanically or chemically (11).

The use of an appropriate chemical (herbicides H) with an appropriate dose may convert the noxious plant biomass into certain beneficial components, e.g. detritus (D) for detritivorous animals or fish, or the dead mass will be converted into nutrient to stimulate the growth of phytoplankton and zooplankton (P) for planktonivorous animals or fish.

The use of herbicides can also be implemented to reduce the extremely abundant growth of the weed that utilization can not cope with.

Furthermore, the safe use of herbicides can be improved through various recent methods developed, e.g. the use of a slow-released herbicide. This started in 1970 with several forms of 2,4-D and silvex were formulated in polyvinyl acetate, polyvinyl chloride and polyamide plastics and evaluated against watermilfoil (*Myriophyllum demersum*) with reasonable results (Cardarelli & Cardarelli, 1982). A number of aquatic herbicidal materials utilizing a thermoplastic binder with a porous additive and one of several agents were developed in 1980. Herbicides evaluated were diuron, simazine, diquat, fenac, bromacil, atrazine, dichlobenil, and several forms of 2,4-D. Recently alginate, crumb rubber, and latex have been used to formulate slow-released herbicides with considerable success.

5.6 Combination

It is to be noted that no single method will guarantee the success of any effort in aquatic weed management. It has to be evaluated carefully in a limited scale if a novel method is to be introduced as an alternative for the

less effective conventional method. In general it can be concluded that a combination of several appropriate methods is in many cases recommended.

The integration of compatible efforts is hopefully the most appropriate answer to the question of how to manage fresh water vegetation optimally for all forms of life including mankind.

CONCLUSIONS

It is concluded that aquatic weed problems has to be viewed as an opportunity, which means that the structure and function of the species concerned in the environment have to be appropriately taken into consideration before any control measure is implemented.

The ultimate results of any cultural method and any potential side effect or risk have to be studied carefully if energy is not to be wasted and potential resource is not to be converted into detrimental wastes or pollutants.

The use of herbicide and any other conventional control method is not excluded in an environmentally sound aquatic vegetation management.

As in any other effort, detrimental impact has to be eliminated at least mitigated, while the residual impact is to be compensated with other beneficial pay-offs. In the use of herbicide some of the recently known impact to be taken into consideration are among others the development of resistance of plant species after being repeatedly treated with the same herbicide.

It is obvious that to be able to exist happily in a healthy environment, men must understand their appropriate niche in the ecosystem, and able to maintain their interrelationship and interdependency with other components in it. They have to know and understand the other companions in the system. Since aquatic weeds or aquatic vegetation is part of their companion, knowing and understanding the biology of aquatic weed flora is part of knowing and understanding their own niche. This will be part of men's effort to be able to develop aquatic vegetation management appropriately for the benefit of all.

Since men are part of nature, as Ernest Partridge (1984) said, human beings have a genetic need for natural environments. They also have a fundamental need to care for things outside themselves, and human life

will be enriched by a transcending concern and responsibility for the wellbeing of natural species, habitats, and ecosystem. By so doing, men enrich the quality of moral life. Persons with genuine reverence and respect for a healthy environment have to control and reduce their demands, but hopefully they will enjoy greater fulfilment in their own lives and be better companions to each other.

WEEDS AND THE ENVIRONMENT IN THE TROPICS
(Eds. K. NODA & B.L. MERCADO), pp. 51-74, 1986

TECHNOLOGY AND ECONOMICS OF WEED CONTROL IN BROADCAST-SEEDED FLOODED TROPICAL RICE

S.K. DE DATTA and J.C. FLINN

The International Rice Research Institute, Los Baños (P.O. Box 933, Manila), Philippines.

Abstract. Increases in labor cost, irrigated area, the development of modern early-maturing varieties, and improved weed management techniques have encouraged many farmers in Thailand, Malaysia, and the Philippines to switch from transplanted to direct-seeded flooded rice culture.

Based on research at IRRI during the late sixties, butachlor and thiobencarb are now marketed in 22 and 56 rice-growing countries, respectively, in the world. Farm-level constraints research demonstrates that the benefit cost ratio from using chemical weed control technology is high in irrigated rice culture.

Alternative weed control technology is being developed for direct-seeded flooded rice to reduce cost, minimize herbicide toxicity, and increase grain yield and income. The use of these alternative technologies, however, will depend largely on the weed situation, and the relationships between labor and herbicide prices.

INTRODUCTION

Direct seeding of rice is extensively practiced in temperate rice-growing countries such as the United States, Australia, Italy, and Portugal (De Datta, 1981). However, in most tropical Asian countries, direct seeding was not widely practiced before the late seventies due to difficulties in weed control, extensive rat and bird damage, snail infestations, and poor irrigation water control (Mabbayad and Obordo, 1971). Direct seeding of rice in tropical Asia is performed either by broadcasting or drilling seed onto puddled wet (wet seeding) or dry soil (dry seeding). Wet seeding

requires 2-3 labor days per hectare. This practice is labor saving and cost-reducing compared to the 15 or more days necessary to transplant a hectare of rice seedlings.

Historically, the weed problem was a dominant constraint to the widespread adoption of broadcast-seeding. It is for this reason that this paper focuses on advances in weed control technology in broadcast-seeded rice; a necessary condition for the current, rapid adoption of this practice in Asia.

Research conducted by IRRI in the early seventies showed that shallow (less than 2.5 cm) continuous flooding contributed to weed growth and so increased weeding costs. Under shallow but continuous flooding, there were more sedges and broadleaf weeds and grasses, while with 15 cm of standing water, grasses and sedges were practically suppressed (De Datta *et al.*, 1973). According to a recent survey, about 34 species in 18 genera under 14 families are important weeds in the Muda rice-growing area of Malaysia where broadcast seeding is extensively practiced (Ho, 1984). *Monochoria vaginalis* (Burm. f.) Presl was the dominant weed species followed by *Fimbristylis miliacea* (L.) Vahl, *Leersia hexandra* Sw., *Jussiaea repens* L., *Scirpus grossus* L.f., *Isachne globosa* (Thunb.) O.K., and *Scirpus juncooides* Roxb. These together with *Cyperus haspan* L. and *Marsilea crenata* Presl infested not less than 75% of the rice-growing areas in Muda area (Ho, 1984). With the recent increase in mechanization in Muda, weed seed contamination in the rice fields has led to widespread emergence of *Echinochloa crus-galli* (L.) Beauv. ssp. *hispidula* (Retz.) Honda, *Echinochloa glabrescens* Munro ex Hook.f., and *Leptochloa chinensis* (L.) Nees.

In Thailand, weeds in broadcast-seeded flooded rice areas are similar to transplanted rice areas except the infestation is more severe with pre-germinated rice (Vongsaroj, 1985). The major weeds in broadcast-seeded flooded rice are: *E. crus-galli* ssp. *hispidula*, *L. chinensis*, *Echinochloa colona* (L.) Link, *Sphenoclea zeylanica* Gaertn., *Mimulus orbicularis* Benth, *M. vaginalis*, *Cyperus difformis* L., *F. miliacea*, *Eleocharis dulcis* (Burm.f.) Henschel, *M. crenata*, *Chara zeylanica* KL. ex. Wild.

In the Philippines, the principal weed species are *E. glabrescens*, *E. crus-galli* ssp. *hispidula*, *C. difformis*, *M. vaginalis*, and *S. zeylanica*.

REVIEW OF LITERATURE

Chemical weed control combined with other cultural practices is now a practical way to reduce weed competition, crop losses, and labor costs. In most instances, the use of herbicides is a practical, effective, and economical means of reducing weed competition and production losses.

The recent expansion in broadcast-seeded flooded rice culture in Malaysia, Thailand, and the Philippines resulted from a combination of technical and economic factors. Technical changes included a) the release of modern rice varieties with high seedling vigor and tillering capacity which increased the crop's competitiveness with weeds, b) improved water control, and c) the availability of selective herbicides such as butachlor and thiobencarb which effectively control weeds in wet-seeded rice (De Datta, 1981; Moody and Cordova, 1985). Long-term trends in the Asian rice farmer's economic environment which facilitated direct seeding included a) falling real prices of rice and herbicides and b) increasing labor costs for transplanting and weeding. Thus, the adoption of wet seeding is a rational response by rice farmers to a cost-price squeeze in rice production (Flinn and Mandac, 1985).

Wet seeding has become an increasingly important method of rice crop establishment in South-East Asia since the late seventies. In Central Luzon -- the "rice bowl" of the Philippines where most of the rice crop is irrigated -- the percentage of farmers adopting wet-seeded rice increased from less than 2% in 1979 to possibly over 80% by 1984 (Coxhead, 1984; Moody and Cordova, 1985). Also the adoption of wet seeding has been similarly spectacular in both favorable and unfavorable rainfed rice environments of the Philippines; it has contributed to early first-crop establishment and increased rice crop intensification (De Datta, 1981; Mandac *et al.*, 1982). The most widely used herbicides in broadcast-seeded flooded rice in the Philippines are now butachlor and thiobencarb.

In Thailand, at least 0.8 million ha was planted to broadcast-seeded rice in 1985, in Malaysia the area under direct seeding possibly exceeds 40,000 ha (De Datta, 1985). Some commonly used herbicides in broadcast-seeded flooded rice in Thailand are butachlor, thiobencarb, oxadiazon, and piperophos + dimethymetryn (Vongsaroj,

1985). Nearly 40% of the Muda rice area alone was direct-seeded by 1983 (De Datta, 1985). Practically all farmers used herbicides in direct-seeded rice in the Muda area (Ho, 1984). The most common herbicide was 2, 4-D butyl ester applied 25-30 days after seeding (DAS) which controls only annual broadleaved weeds and sedges. Other herbicides currently being tested are trifluralin, piperophos, pyrazolate, molinate, fluazifop-butyl, butachlor, thiobencarb, and oxadiazon.

IRRI results show that several herbicides were effective in controlling weeds and increasing grain yield of broadcast-seeded flooded rice. In 1968, IRRI began herbicide testing with national programs. The results of IRRI research and with cooperating countries encouraged broad usage of butachlor (22 countries) selected at IRRI in 1968 (IRRI, 1969), and thiobencarb (56 countries) selected in 1969 (IRRI, 1970). Butachlor and thiobencarb, earlier reported as highly selective on broadcast-seeded flooded rice (De Datta and Bernasor, 1971, 1973; De Datta, 1981; De Datta and Herdt, 1983), were occasionally moderately toxic to rice when combined with 2, 4-D. This symptom occurred most frequently when plants had too much water or when the herbicides were applied during cold weather. However, rice plants often recovered from this herbicide injury.

Other cultural practices that minimize weed competition in broadcast-seeded flooded rice are the degree of puddling and land leveling, fertilizer and water management (Bernasor and De Datta, 1983; Vongsaroj, 1985).

MATERIALS AND METHODS

Preliminary Herbicide Screening

Three screening trials were conducted at IRRI during the 1982 dry and wet seasons and the 1984 wet season to identify herbicides that would complement other weed control methods in direct-seeded flooded rice. Each experiment was laid out in a randomized complete block design replicated three times. Most of the herbicides were applied at early postemergence of weeds (2-3 leaf stage).

Advanced Herbicide Screening

Advanced screening trials were conducted at IRRI, and at Maligaya and

Bicol Rice Research Stations during the dry season, and at these sites and the Visayas Rice Research Station during the wet season. The experiments at each site were laid out in a randomized complete block design replicated four times. The herbicides were applied 6-8 DAS. *E. crus-galli* ssp. *hispidula*, *E. glabrescens*, *M. vaginalis*, and *C. difformis* were common at all sites.

Time of Herbicide Application

The effect of application time and rate of three postemergence herbicides on weed control and on direct-seeded flooded IR36 yield was studied at IRRI during the 1983 dry season. Propanil at 1.5 and 3.0 kg/ha, bentazon at 1.0 and 2.0 kg/ha, and fluazifop-butyl at 0.05 and 0.10 kg/ha were applied at the 2-3 and 5-7 leaf stages, and at the tillering stage of the rice crop.

Chemical Control of Scirpus maritimus

Time of application. Effect of application time of bentazon and 2,4-D was examined at IRRI in the 1982 wet season. Bentazon at 1.0 kg/ha and 2,4-D at 0.75 kg/ha were applied 15 and 25 DAS in randomized complete block design. Each treatment was replicated four times. Butachlor at 1.0 kg/ha was applied to all plots 6 DAS to control annual weeds.

Single vs combined herbicide application. An experiment conducted during the 1983 dry season compared the effects of single and combined herbicide treatments on *S. maritimus* control in direct-seeded flooded IR36. Bentazon, propanil, and 2,4-D were applied singly and combined with each other as tank mixtures 25 DAS. The treatments were arranged in a randomized complete block design and replicated four times. Butachlor at 1.0 kg/ha was applied to all plots 6 DAS to control annual weeds.

Integrated Weed Control

The long-term effect of tillage, cultivar, and herbicides are being examined in an experiment initiated in the 1984 dry season. The experiment was laid out in a factorial randomized complete block design replicated three times on an area kept in weedy fallow for 3 months. Tillage levels were 1 harrowing, 2 harrowings, and 3 harrowings, each preceded by 1 plowing. The cultivars used were IR36, a semidwarf, and IR29723-143-3-2-1, an intermediate tall. The herbicide

treatments consisted of bensulfuron-methyl (0.05 kg a.i./ha) applied 10 DAS, propanil + 2,4-D (1.5 + 0.5 kg a.i./ha) applied tank-mixed 15 DAS, and an untreated check. There were 17 weed species present before the start of the trial.

Farm-level Constraints Trial

During the 1984 dry season, experiments were conducted in farmers' fields in Nueva Ecija, Bulacan, and Camarines Sur provinces, Philippines to evaluate IRRI-developed weed control technology against farmers' current weed control practices.

Farmer-application of Wet Seeding/Herbicide Technology

Farmer's use of wet seeding and herbicides were evaluated through farmer surveys in Central Luzon and the Bicol region of the Philippines. These two sites were chosen as contrasts in wetland rice culture as Central Luzon is the highest yielding region of the Philippines and Bicol among the lowest. Yet wet seeding is widely used by farmers in both regions, in the former case with irrigation, in the latter case under irrigated and shallow rainfed conditions.

RESULTS AND DISCUSSION

Preliminary Herbicide Screening

The major weeds present during the preliminary herbicide screening were *E. crus-galli* ssp. *hispidula*, *E. glabrescens*, *M. vaginalis*, *C. difformis*, and *S. maritimus*.

In the 1982 dry season trial, the molinate/R-24216, molinate/2,4-D EPTC/2,4-D treatments, and the butachlor check gave similar yields which were significantly higher than the yield in the untreated control (Table 1). Yield in other treatments did not differ from the untreated check.

In the wet season, all herbicide treatments gave significantly higher yields than the untreated check (Table 2). The granular formulation of a new herbicide, bensulfuron-methyl, applied at 0.05 kg/ha 6 DAS, provided excellent control of broadleaf and grassy weeds and very good control of the perennial sedge *S. maritimus* without affecting the rice crop. Oxyfluorfen and thiobencarb/2,4-D also provided excellent

control of the annual weeds but did not control *S. maritimus*. These herbicides were slightly toxic to rice.

Five herbicides and herbicide combinations gave significantly higher yields than those in the untreated control in the 1984 wet season trial (Table 3). Quinchlorac controlled weeds effectively, caused only slight crop injury, and produced significantly higher yields than did the thiobencarb/2,4-D check and other herbicide treatments. Naproanilide/butachlor, SC-0254, and the pyridate compounds were highly toxic to rice.

In the advanced herbicide screening trials conducted during the dry and wet seasons, the average yield over 3 years and 3/4 sites with all the herbicide treatments were significantly higher than the untreated check (Table 4). Plots treated with naproanilide/thiobencarb yielded significantly higher than plots treated with pendimethalin, butachlor, and butachlor + 2,4-D. Butachlor with or without 2,4-D was occasionally toxic to rice in some sites. Pendimethalin poorly controlled *C. difformis* and *Cyperus iria* L.

Time of Herbicide Application

In the study of herbicide application time, most herbicides applied at 2-3 leaf stage controlled weeds (predominantly *S. maritimus* and *C. iria*) but not as effectively as three hand weedings (Table 5). Bentazon (1.0) and propanil (3.0) applied at 5-7 leaf stage were as effective; they significantly reduced weed biomass when sprayed at tillering stage at both rates. They were more effective when applied toward the tillering stage when weeds were older and had more top growth. Fluazifop-butyl was consistently poor in controlling weeds regardless of application time. Bentazon at both rates and propanil at a higher rate yielded significantly higher than the untreated check. The highest average yield of 1.7 t/ha obtained from bentazon-treated (1.0) plots was comparable with those of other treatments except with fluazifop-butyl at 0.1 kg/ha which was significantly lower.

Chemical Control of Scirpus maritimus

In the study of chemical control of *S. maritimus*, bentazon and 2,4-D were superior in controlling weeds when applied at 25 DAS (Table 6). Bentazon controlled *S. maritimus* better than 2,4-D because it gave significantly less weed biomass than the untreated check applied 15 DAS, which was comparable with 2,4-D applied 25 DAS. Weed biomass with 2,4-D applied 15 DAS and the untreated were similar. However, both herbicides were safe on rice and gave significantly higher yields than the untreated control regardless of application time.

Integrated Weed Control

In the integrated weed control experiment, the cultivars did not affect weed stand in the first crop (DS) (Fig. 1). Approximately the same number of *P. distichum*, *S. maritimus*, and annual weeds was observed in the short IR36 and tall IR29723. However, there was a slight decrease in *P. distichum* and an increase in *S. maritimus* and annual weeds when tillage was increased from 1 to 3 harrowings. *S. maritimus* and the annual weeds were controlled only with bensulfuron-methyl and propanil +2,4-D application (Fig. 1) resulting in significant yield increases in IR36 plots that received 1 and 3 harrowings and in IR29723 plots the received 2 and 3 harrowings (Table 8).

In the second crop (WS), 3 harrowings gave the lowest *P. distichum* stand, but again did not minimize *S. maritimus* and annual weed

Fig. 1. Weed population in the first crop as affected by cultivar (C₁ = IR35, C₂ = IR29723-143-3-2-1), tillage (T₁ = 1 harrowing, T₂ = 2 harrowings, T₃ = 3 harrowings), and herbicide (H₁ = bensulfuron-methyl, H₂ = propanil+2,4-D, H₃ = untreated) in broadcast-seeded flooded rice, IRRI, 1984 DS.

infestations better than with either 1 or 2 harrowings (Fig. 2). The IR29723 plots were only slightly less weedy than the IR36 plots. Herbicide-treated plots had substantially less *S. maritimus* and annual weeds regardless of tillage level. Yields with both herbicide treatments were significantly higher than in untreated IR36 plots harrowed once and thrice and in IR29723 plots harrowed twice and thrice (Table 9).

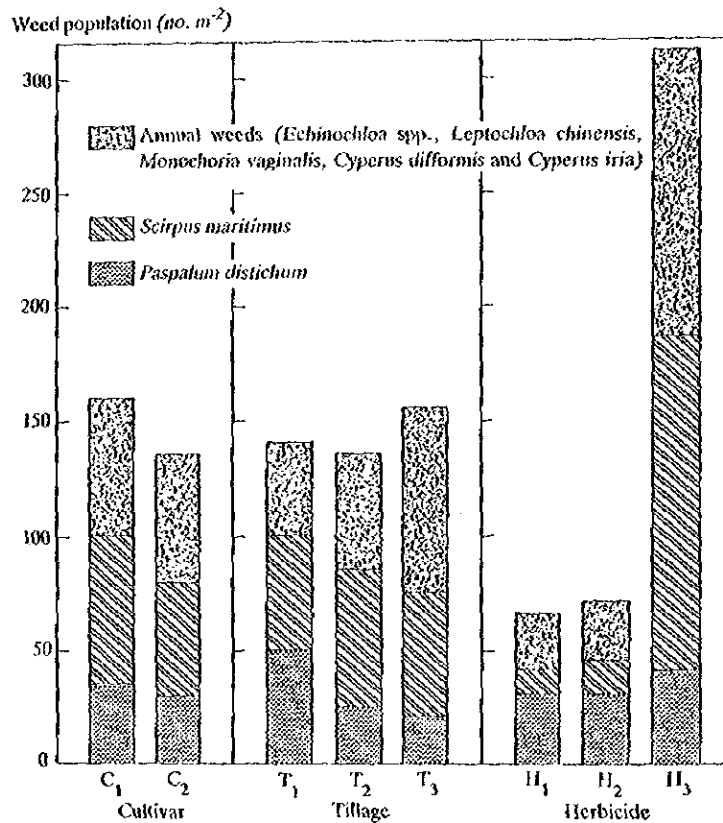

Fig. 2. Weed population in the second crop as affected by cultivar (C₁ = IR36, C₂ = IR29723-143-3-2-1), tillage (T₁ = 1 harrowing, T₂ = 2 harrowings, T₃ = 3 harrowings), and herbicide (H₁ = bensulfuron-methyl, H₂ = propanil+2,4-D, H₃ = untreated) in broadcast-seeded rice. IRRI, 1984 WS.

Results from both crops indicate that cultivar type had no effect in minimizing weed competition. However, a slight decrease in *P. distichum* was observed with an increase in tillage level. Bensulfuron-methyl and propanil + 2,4-D application effectively controlled *S. maritimus* and the annual weeds which consequently resulted to higher yields.

Farm-level Constraints Trial

On-farm experiments showed that herbicides in combination were not necessary to control single weed vegetation for optimum rice yields. IRRI constraints research data show that the contribution of improved herbicide weed control accounted, on average, for about 30% of the yield gap over farmers' weed control practices, but that actual contributions varied enormously across sites and over years (Fig. 3). The benefit to cost ratio of the researcher's weed control, when compared to farmer's practices, were extremely high in the dry season, and on average, exceeding 20 : 1, except for Bulacan in 1985.

Farmer Management of Broadcast-Seeding

Farmer's rice yields in Central Luzon are essentially double that recorded in the Bicol region (Table 10). In the irrigated sites in Central Luzon, mean rice yields, over 4 t/ha, did not differ between methods of crop establishment. However, in the rainfed rice systems in Bicol, yields were significantly higher in the transplanted (2.4 t/ha) than the wet-seeded (1.9 t/ha) sites. The yield difference in Bicol was ascribed in part to differences in fertilizer use and, while not reported, in the higher incidence of weed infestation and moisture stress in wet-seeded parcels (Mandac *et al.*, 1982).

Farmers in both Central Luzon and Bicol who direct-seeded used significantly higher seed rates than those who transplanted their rice. Seeding rates were well in excess of those recommended for transplanted (40 kg/ha) or for wet-seeded (60-90 kg/ha) rice in the Philippines. Farmer's high seeding rates with direct seeding are in effect a substitute for herbicides and hand weeding. High seeding rates also compensate for uneven seed distribution and stand loss due for example to birds, rats or uneven land preparation. The Central Luzon farmers on average applied almost twice as much herbicide to direct-seeded compared to transplanted rice. However, in Bicol, the opposite was the

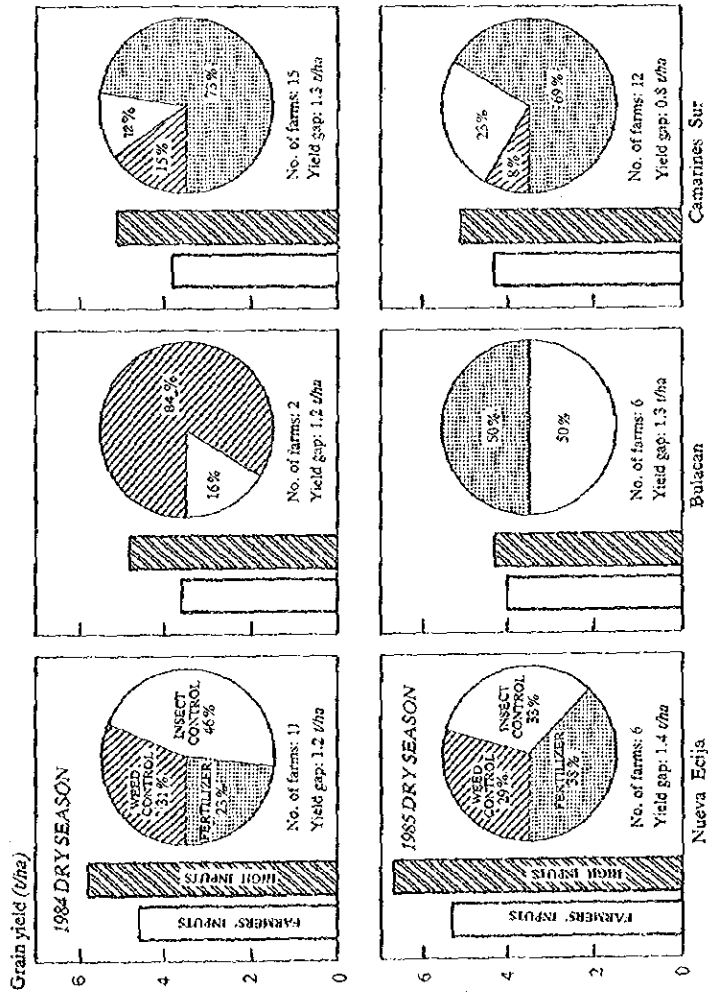

Fig. 3. Average yields with farmers and high inputs and relative contributions of fertilizer, weed control, and insect control toward improvement of rice yields on broadcast-seeded irrigated farms in 3 provinces in the Philippines, 1984 and 1985 dry seasons.

case, partly a reflection of the fact that the most resource-poor farmers adopted wet seeding most widely in an attempt to reduce production costs (Flinn and Mandac, 1985).

The greatest saving from wet seeding is reduced labor inputs which saved farmers 20 labor days/ha or more, or over ₱400/ha (US\$22/ha) mainly for transplanting. This saving, even after the cost of higher seed rates and possibly herbicides are allowed for, substantially reduces rice production costs and so helped sustain the profitability of rice production.

DISCUSSION

Innovations in weed management based on judicious use of recently identified herbicides have resulted in wet seeding emerging as a viable alternative to transplanting in areas with reasonable water control during crop establishment. Important technical issues which may influence the sustainability of this technique include whether yields are maintained and whether herbicides continue to control weed species which may become dominant as wet seeding is adopted on a sustained basis. Another is

whether water control at seeding time will constrain expanded use of this technology. Future economic circumstances will also determine the expanded use of this technology.

The emerging Asian rice scenario seems to be that rice supplies are increasing at a more rapid rate than is effective demand, and as a result, real rice prices are tending to fall (IRRI 1985). Yet the real cost of inputs has not decreased in a similar manner. Thus, the Asian rice farmer is facing a cost-price squeeze -- and so seeks alternative practices which will enable him to maintain productivity and profitability in rice production. Among these strategies are direct seeding and herbicide use, which helped reduce production costs by reducing labor inputs for crop establishment and for weeding.

The adoption of wet seeding in the Philippines was facilitated as herbicides have become cheaper compared to labor (Fig. 4). Whether this incentive for broadcast-seeding continues will in part depend on government policies with respect to trade controls and monetary and exchange rate policies which will help determine herbicide prices as most Southeast Asian countries now import the active ingredients of herbicides. This, together with the level of market competition, will in aggregate help determine the market prices of herbicides, and the competitiveness of herbicides and labor. A second determinant of the

Fig. 4. Long-term trends in real prices of herbicides in the Philippines, 1975-1983.

long-term profitability of broadcast-seeding is the trend in real wages (Fig. 5). In Malaysia, North Sumatra, and the Central Plain of Thailand where real wages are rising, direct-seeding is likely to expand more rapidly than for example in Central Java or South Sulawesi where real wages are comparatively low. Indonesia, however, provides an interesting contrast. In Central Java there appears to be little incentive to shift towards broadcast seeding, yet in North Sumatra, the financial incentive appears high. In Thailand, mechanization is rapidly taking place in land preparation and community threshing. Broadcast-seeding and herbicide usage are steadily increasing to decrease cost of production and labor usage. Alternatively, stagnation in real wages may act as a deterrent to the current rapid rate of adoption of this practice in the Philippines.

Fig. 5. Long-term trends in real agricultural wages in Indonesia, Malaysia, the Philippines, and Thailand. Real wage derived at wage rate per day divided by the price per kg of milled rice.

DISCUSSION OF THE PAPERS OF H. SHIBAYAMA,
M. SOERJANI AND S.K. DE DATTA
(Chaired by K. Noda)

Dr. M. Blacklow (Australia): Dr. Y.K. De Datta, your comparison of direct seeded and transplanted rice were based on single crops. Are there any differences in the conclusions when the comparisons are made on the basis of cropping systems?

Dr. S.K. De Datta (Philippines): The switch is much larger in the dry season than in the wet season. If we examine crop establishment technique on an annual basis, most of the farmers are using the broadcast seeding in the dry season than growing a transplanted crop in the wet season.

In the rainfed rice areas, depending on the initial rainfall, farmers would decide to grow either transplanted crop or broadcast seeding into dry or moist soils. The switch to broadcast seeding is greater where a rice-rice system is used. The switch to broadcast seeding is more in irrigated rice on puddled fields and is less in rainfed rice.

Dr. S.K. Mukhopadhyay (India): No doubt the direct seeded flooded rice system has the distinct advantage of saving considerable labor cost, yet there are many people who have problems on toxicity-injury of herbicides in direct-seeded flooded rice crop as compared to transplanted rice crop. When herbicides are applied, transplanted seedlings being older are less prone to herbicide injury.

Dr. S.K. De Datta: No herbicides would be recommended when the toxicity is consistent and also persistent. Our recent results suggested that when the herbicide application is made before seeding, the toxicity is considerably reduced. At the time of herbicide application if the seedlings of broadcast-seeded rice are mostly submerged under water, then the

herbicide injury will be high. Therefore, proper water control at the time of herbicide application is important to minimize seedling injury and maximize weed control.

Mrs. Rajanee Virabalin (Thailand): Dr. M. Soerjani, is it possible that by choosing an appropriate technology to use aquatic weeds as a raw material, the aquatic weeds will be changed to be economic crops?

Dr. M. Soerjani (Indonesia): Yes, it might be. A typical example is wild rice. Some of the species of wild rice now become cultivated crops, while the rest (e.g. *Oryza perennis* and *O. rufipogon*) still have status as weeds.

Dr. M. Blacklow (Australia): Dr. M. Soerjani, you seemed to be advocating constraints with the expansion of the biological control of aquatic weeds and concluded that control with herbicides is localised and would, therefore, allow any advantages of aquatic weeds to be exploited. Would you care to emphasize this advice?

Dr. M. Soerjani : I have no objection to the implementation of conventional biological control. However, I am questioning: when you add a component in the trophic structure, namely by releasing an insect as a biological control agent to control a weed, you have to know what will be the end of the trophic pyramid. If you don't know what will happen with the insect or what will be the top component of the new trophic pyramid, there will be an unknown risk.

In most biological control efforts with insect for instance, the other role of an insect except as a phytophagous agent is mostly unknown. Since actually the insect may also serve as pollinators of crops or other economic plants. This is a beneficial side effect of a control agent.

The use of herbicides in aquatic weed control may offer a broader opportunity by converting the biomass into others, e.g. detritus, phytoplanktons and zooplanktons, that can be utilized by a variety of fish in a more proper way. Furthermore, if aquatic weed utilization is not feasible because of the small amount of the biomass, preventive control measure might be more appropriate by using herbicides.

Dr. Lee Soo Ann (Malaysia): Dr. M. Soerjani, you mentioned that aquatic weeds harbour mosquito larvae, which may spread malaria. I

have heard of reports of strains of malaria parasites resistant to the usual doing in Sabah and perhaps Indonesia. Can you please comment on the aquatic weed species which specifically harbour this parasite and what are your views on their control?

Dr. M. Socijani: In general, water is a living place for mosquito larvae, and since they are high in the trophic level, they need certain support from the lower level of the trophic structure, including primary producers, e.g. aquatic plants.

Dr. K. Noda: We had many papers on *Mimosa pigra* in the concurrent session, and Dr. Onnop, Chiang Mai University have new, current information on it around these areas, I think. Please give us any comment.

Dr. Onnop Wara-Aswapati (Thailand): We had many papers and reviews on *Mimosa pigra* in the concurrent session including Dr. Shibayama's paper in this Symposium and observation on a field trip to infested areas. I think, there is no need to add any comment on current situations. But I would like to ask two points: 1) what is the best method of *Mimosa pigra*'s control and/or managements?, 2) what should be emphasized in future research for *Mimosa pigra*?

Dr. H. Shibayama (Japan): In a long term sense, biological control is useful, but in a short term one, combination of herbicides and manual methods is necessary, I would say. As for research programme, the utilization of landsat will be interested to know the change of *Mimosa pigra* vegetation. Biological works such as seed germination presented by Dr. W.H. Lonsdale in natural conditions are very important to know how it propagates and spreads to new other areas. Further, physiological analysis of how *Mimosa pigra* adapts to flooding conditions, and biological works to find weak points of *Mimosa pigra* for control are very important, I think.

WEEDS IN SHIFTING CULTIVATION IN THAILAND

Tem SMITINAND

The Forest Herbarium, Royal Forest Department, Bangkok 10900, Thailand

Abstract. Shifting cultivation under customary practice is undertaken into 2 forms: annual and rotary. Under both practices weeds are constantly encroached during and after cultivation.

The most noxious weeds in the annual cultivation, commonly practised by the hill tribes; i.e. Maco, Musoe and Yao are Saap ma, (*Ageratina adenophora* (Spreng.) R.M. King & M. Robins., Phak hai (*Artemisia dubia* Wall. ex DC.) and Thaan tawan nuu or Bua tong (*Tithonia diversifolia* Gray), which become gregarious all over the area after such cultivation.

The rotary shifting cultivation causes less noxious weeds, as the land was left to fallow for a period of 5-9 years: the most noxious weeds are Saap suea (*Chromolaena odorata* (Linn.) R.M. King & B. Robins) and Khaem (*Saccharum arundinaceum* Retz.).

However, Ya khaa (*Imperata cylindrica* Beauv.) is the noxious weed in both types of shifting cultivation.

INTRODUCTION

The First Tropical Weed Science Conference was held at Haad Yai, Songkhla, Thailand during 22-25 October 1984, of which many topics on weeds were discussed, especially in the lowland, with only a mere touch on the highland. It appears that among the ten top weeds, the Lallang grass (*Imperata cylindrica*), Purple nutsedge (*Cyperus rotundus*), and Saap suea (*Chromolaena odorata*) occur both in lowland and highland. The aim of this paper is to enumerate weeds in the shifting cultivation among the highland.

Weeds can be defined as plants out of place or unwanted plants, or

plants with a negative value, or plants which compete with man for the soil. They can be classified into 2 categories: obligate and facultative (SEN, 1981). The obligate weeds are occurring only in association with man and never in wild form, such as Ngon kai or Dok daai (*Celosia argentea*), Saap ma (*Ageratina adenophorum*), Saap suca (*Chromolaena odorata*), Maiyaraap ton (*Mimosa pigra*), Thaan tawan nuu (*Tithonia diversifolia*), etc. The facultative weeds are found both wild in primary habitats and with man in cultivated habitats, such as, Saap raeng saap ka (*Ageratum conyzoides*), Phaak hia (*Artemisia dubia*), Yaa khi thut (*Artemisia roxburghiana*), Khaem (*Saccharum arundinaceum*), Yaa tong kong (*Thysanolaena maxima*), etc.

Shifting cultivation practised in Thailand is undertaken into two forms: annual and rotary. The annual shifting cultivation is done by hill tribes in Northeastern Highland, namely Maeo or Hmong, Yao, Musoe or Lissu living at higher elevations from 1,000 m upwards, they are half nomads. These people grow their crops annually, such as corn for their staple food, and opium poppy as cash crop. Under their practice the land is properly cleared and continually cleaned to ensure the highest yield; thus except the crops cultivated, the land is almost without any other ground cover. During the time of cultivation the soil is exposed to the sun and rain, causing rather high evapotranspiration and water run off. After harvest the soil is totally barren, and subject to very high evapotranspiration and surface erosion, caused either by wind or water run-off.

Plant succession under this trying condition is subject to noxious weeds such as Saap ma (*Ageratina adenophora*), Phak hia (*Artemisia dubia*), and Yaa khi thut (*Artemisia roxburghiana*), gregariously occupying the open ridges and slopes; whereas along the rather humid valleys Thaan tawan nuu or Bua thong (*Tithonia diversifolia*) is preponderate. If such areas are continually subject to annual fire, the above mentioned weeds might be encroached by grasses such as : *Arundinaria setosa*, *Capillipedium assimile*, *C. parviflorum*, *Cymbopogon flexuosus*, *Heteropogon triticeus*, *Imperata cylindrica*, *Saccharum arundinaceum*, *Themeda arundinacea*, *T. triandra*, *Thysanolaena maxima*, etc.; the ferns, *Dicranopteris linearis* and *Pteridium aquilinum*, become widespread. The full list of species is given in Table 1.

The rotary shifting cultivation is practised by other hill tribes inhabiting lower elevations from 600m upwards, such as : Karen and Lawa

or Lua. These people are stationary and grow wet-rice for their staple food with additional shifting cultivation to supplement their income. The rotary system of shifting cultivation has a rotation from 5-9 years; after harvest the land is left to fallow between the rotation. Under this system the land is not properly cleaned, stumps are left around, which will coppice after the harvest. Plant succession in these areas is subject to hardy tree species lately coppiced, shrubs and other annual herbs such as Saap raeng saap ka (*Ageratum conyzoides*) Phak kaat chang (*Crassocephalum crepidioides*), and Yaa tom tok (*Physalis minima*), which later are superseded by the perennial herbs, Saap suea (*Chromolaena odorata*) (Nemoto & Pongsuk, 1985) and other perennials such as Yaa khai luang (*Arundinella hispida*), Yaa saeng kham (*Hyparrhenia rufa*), Yaa kha (*Imperata cylindrica*), Khaem *Saccharum arundinaceum*, and Yaa tong kong (*Thysanolaena maxima*). The full list of species is given in Table 2.

MAJOR WEEDS IN HIGHLAND SHIFTING CULTIVATION

The major weeds in highland shifting cultivation in Thailand belong to two groups of plants, i.e. Pteridophyta or vascular ferns and Spermatophyta or seed plants.

PTERIDOPHYTA.— Only two species of vascular ferns, Kut pit (*Dicranopteris linearis*) of the family Gleicheniaceae and Kut kin (*Pteridium aquilinum*) of the family Dennstaedtiaceae are recognized as noxious weeds.

Dicranopteris linearis (Burm.f.) Underw. is very widespread all over the country in old clearings, usually at edge of forests, in open or half-shaded places at low to medium altitudes.

Pteridium aquilinum (Linn.) Kuhn is found all over the country in open areas, upto 2,000 m alt. It is one of the acidiphilous plants, usually forms a big thicket at edge of forests, or recent clearings in sunny places, and frequent in the pine forests. The young fronds are cooked to substitute vegetable, and starch is available from rhizome.

SPERMATOPHYTA.— Quite a number of seed plants are identified as weeds, but the majority belongs to families Gramineae, Acanthaceae,

and Compositae.

Gramineae or the grass plant. Grasses are either annual or perennial. The annual species are not noxious weeds, only the perennials ones play an important role in weed science. Annual species such as Yaa khon kratai (*Aristida cumingiana*), Yaa yung (*Capillipedium assimile*, *C. parviflorum*), Yaa paak khwaai (*Digitaria violascens*), *Dimeria ornithopoda*, Yaa kon hep (*Eragrostis capensis*), Yaa khai puu (*Eragrostis unioloides*), Yaa khanaeng (*Rytidix granulata*), etc. are found after the harvest of crops, but later will be suppressed by the perennial ones. such as *Arundinella setosa*, *Cymbopogon flexuosus*, *Eulalia siamensis*, Yaa saeng kham (*Hyparrhenia rufa*), Khaem (*Neyraudia reynaudiana*), Khaem luang (*Themeda arundinacea*), and Yaa tong kong (*Thysanolaena maxima*).

Among these grasses *Imperata cylindrica* is well established becoming the most noxious weed difficult to eradicate. It is subject to fire and is a check against any pioneer species to establish. Even tall grasses such as *Arundinella setosa*, *Themeda arundinacea* and *Saccharum arundinacum* hardly exist.

Acanthaceae weeds, mostly annuals, namely *Rostrellularia chiang-maiensis*, *R. cradengensis*, *R. neglecta*, *Rungia maculata*, and *Barleria cristata* although established after harvesting of crops are superseded by *Imperata cylindrica* and other grasses, except *Barleria cristata* that exists scatteringly owing to its having fasciculate roots.

Compositae weeds, mostly annuals, i.e. *Anaphalis adnata*, *A. margaritaceum*, *Ageratum conyzoides*, *Bhunea fistulosa*, *B. lacera*, *Crassocephalum crepidioides*, etc. are also superseded by *Imperata cylindrica*, and other perennial tall grasses. Except in certain moister areas perennials such as *Artemisia dubia*, *Chromolaena odorata*, and *Tithonia diversifolia* become preponderate. The annual *Ageratina adenophylla* is also forming dense masses in moister localities. It is worthwhile to note that among these weeds the exotic species, i.e. *Ageratina adenophylla*, *Chromolaena odorata*, and *Tithonia diversifolia*, which belong to the family Compositae become widespread due to the gregarious flowering in suitable condition. Only the native *Imperata cylindrica* is forming dense stands owing to its matted underground rhizomes and gregarious flowering due to annual fire.

WEED HOSTS OF *MELOIDOGYNE*, THE ROOT-KNOT NEMATODES.

L.E. BENDIXEN .

*Department of Agronomy, The Ohio State University, 2021 Coffey Road, Columbus, Ohio
43210, U.S.A.*

Abstract. Weeds impact on crop production directly through interference and indirectly through hosting other crop pests. The root-knot nematodes are among the most serious pests hosted by weeds. A literature search produced over 2200 entries of weed hosts of root-knot nematodes. They are listed in tables representing 19 nematode species of the genus *Meloidogyne*. These weed hosts represent 113 plant families. The greatest numbers of weed host entries were from the families Leguminosae, Compositae, and Gramineae, followed by Solanaceae, Amaranthaceae, Labiatae, Cruciferae, Malvaceae, Polygonaceae, and Euphorbiaceae. *Solanum* was the genus with the greatest number of entries, followed by *Amaranthus*, *Trifolium*, *Nicotiana*, *Chenopodium*, *Euphorbia*, *Rumex*, *Hibiscus*, *Ipomoea*, and *Vicia*. Dicotyledons are better hosts than monocotyledons of most *Meloidogyne* species. *M. javanica* was hosted by the most weed species, followed by *M. hapla*, *M. acrita*, *M. incognita*, and *M. arenaria*. The objectives of the weed hosts as pest reservoirs activities are to emphasize the overall impact of weeds in crop production, to offer another criterion in defining the importance of weeds, and to promote effective control of weeds.

INTRODUCTION

Weeds are perceived variously. They may be ground cover for erosion control. They may be grazed or harvested for animal feed. They may be medicinal plants or a source of fiber. They may be admired and collected as wild flowers. They may be competitors with crops and reduce crop

yield. They may have no effect on the cosmetic value of crop products. Thus, for many reasons, the image of weeds may not be unfavorable. However, the impact of weeds may be great, yet difficult to judge unless carefully researched.

Several direct and indirect influences of weeds may be responsible for reductions in crop yield. One of the direct influences may result from interference. Competition for light, water, and mineral nutrients is one aspect of interference. Another aspect of interference is allelopathy, resulting from chemical exudations or degradation products which may restrict seed germination, plant establishment, or plant growth. It may be very difficult to distinguish between the effects of competition and allelopathy in crop yield reductions.

Competition from weeds results because of their trophic status, like crops, of being *primary producers*. They are thus involved in the flow of energy and matter. Therefore, they compete, and often vigorously, with crops and other plants for limited supplies of light, water, and mineral nutrients.

As primary producers, weeds may also provide energy, nutrients, and shelter for insects and mites, nematodes, pathogens, and vertebrates, which are primary or secondary consumers. In this relationship, weeds serve as hosts of these other organisms. As hosts, they may also serve as reservoirs by maintaining populations of those organisms. This is an example of an indirect influence of weeds on crop production. Whether the influence is positive or negative is determined by whether the species hosted is beneficial or a pest.

Microclimate modification may be an indirect influence of weed canopies on crops. Among other things, their physical stature and density might alter air movement and relative humidity. In modifying the microclimate, weeds may not only have a direct effect on crop growth, but also an indirect effect. This indirect effect may result from the responses of crop pests to those changes in the microclimate. Pest populations may thus be reduced or enhanced.

The integrated pest management (IPM) concept is usually interpreted as vertical integration for management of one pest species. Use is made of appropriate combinations of preventive, biological, physical-mechanical, and chemical methods or tools in crop cultural practices. In the IPM concept, one utilizes the interacting effects of climate, soil, and crop, in addition to the four tools listed above, in regulating pest populations. If

IPM is to achieve its ultimate goal, it must be perceived also as horizontal integration, integrating control of all classes of pests -- weeds, insects and mites, nematodes, pathogens, and vertebrates. The interrelationships of these five classes of pests might be illustrated as a "pest pentagon" (246). Biological control of pests and biological infection by pests are implicit in the concept of the horizontal integration of IPM and of the pest pentagon. Biological control of pests has been illustrated by many classical and non-classical examples. Biological infection may also be illustrated by many examples. It relates to the infection of one organism by another as a result of the activity of a third organism. One example is the infection of corn (*Zea mays* L.) with maize dwarf mosaic virus by aphids.

The "Weed Hosts as Pest Reservoirs" concept is one approach toward horizontal integration in pest management. The premise is that, if the weed hosts of specific pests -- insect, nematode, pathogen, or vertebrate -- are controlled, the populations of those pests will be reduced. Literature on weed hosts as pest reservoirs and the importance of weed hosts of pests in crop production has been reviewed (38,39,40,41,42,43,44,45,46,47,48,49,104,147,205,206,207,276,353). The difficulty of assigning the relative effects of the direct influence of competition and the indirect influence of pests hosted by weeds on crop yield is akin to the difficulty of distinguishing between competition and allelopathy on crop growth.

ROOT-KNOT NEMATODES

Among the plant-parasitic nematodes, the root-knot (*Meloidogyne*), cyst (*Heterodera*), and lesion (*Pratylenchus*) nematodes may be considered to be the most serious genera, in that order, affecting worldwide crop production. Over 54 species of the genus *Meloidogyne* have been described and named (143a). Of these, *M. incognita*, with four widespread races, *M. javanica*, with one race, *M. hapla*, with one race, and *M. arenaria*, with two races, in that order, were most widely distributed and caused the most crop damage. They very probably cause more damage to farm crops than all other *Meloidogyne* species combined (295).

The first report on *Meloidogyne* may have been that of Berkeley (49) in England in 1855. Subsequently, Jobert (165) reported on root galls of

diseased coffee trees in Brazil, which was researched further by Goeldi (121). The presence of the root-knot nematode in the United States was first reported by Atkinson (25) and Neal (243) in 1889.

M. hapla, a cool climate species often referred to as the northern root-knot nematode, has an optimum temperature range of 15° to 25°C (330). It can survive in frozen soils and regions where the average temperature of the coldest month is near or below 0°C. The upper limit of its tolerance range is about 27°C. It is found where these conditions are met in North and South America, Africa, and Australia. It is the most common *Meloidogyne* species found north of 35°N latitude.

M. incognita, *M. javanica*, and *M. arenaria* are tropical zone nematodes. *M. javanica* does not survive where the isotherm of the coldest month is below 7°C. The lower limit for *M. incognita* is about -1°C. The optimum temperature range for these three species is 25° to 30°C. They are found between 35°N and 35°S latitude and adapted to continuous existence in these warm areas of Africa, Asia, Australia, and the Americas. However, *M. javanica* is seldom found above 30°N latitude. Very little activity occurs in any of these species below 5°C or above 40°C.

Meloidogyne species are obligate plant parasites. Reproduction occurs only when second-stage infective larvae enter roots or other underground parts of suitable host plants, initiate giant cells on which to feed, and develop to egg-laying females (330). Females may continue to produce eggs for 2 to 3 months. Hatching is dependent on suitable soil temperature and soil moisture. The hatched larvae may survive from a few days to a few months. Their migrations in the soil are random until they come within a couple of cm of a root, when their movement is then directed toward the root. Each female may produce many eggs and several generations per year may develop, depending upon favorable temperature and moisture conditions. Infection causes various degrees of stunting, wilting, and malformation which may cause death of the host plant.

As a genus, the root-knot nematodes affect a wide range of vegetable, fruit, grain, forage, and tree crops. Crop losses in technologically developed countries may range from 5% to 10%, while crop losses for small farmers of less developed countries may range from 25% to 50% (330). Root-knot is considered to be one of the most widespread plant diseases of the world.

WEED HOSTS AS PEST RESERVOIRS

The purpose of research on the weed hosts as pest reservoirs concept is to emphasize the role of weeds and the importance of weed control in crop production. The use of weeds for erosion control or for animal feed may be counter productive if those weeds maintain populations of crop-destroying pests. The weed hosts as pest reservoirs concept offers another criterion, in addition to interference by competition or allelopathy, in defining the significance of weeds in crop production (47).

The following section contains over 2200 entries of weeds reported to host specific *Meloidogyne* species. These weed hosts are distributed non-uniformly among 113 plant families. They host one or more of the 19 *Meloidogyne* species included. The publication by Goodey *et al.* (130) was used as a chief source of plant host information to 1965. The weed survey by Holm *et al.* (146) was used to identify which host plants to classify as weeds. For this reason, plants considered by others to be weeds may have been omitted. Only the earliest available report of a plant as a host is included in the tables.

There are 20 weed hosts tables, arranged alphabetically by *Meloidogyne* species hosted. Within each table, the weed hosts are listed alphabetically by plant family, which are also arranged alphabetically. Since uncertainty seemed to exist in the literature in identifying some nematode species, those species identified as *M. incognita acrita* or *M. incognita* and/or *acrita* were arbitrarily listed with *M. acrita* in Table 1. Those species identified as *M. javanica bauruensis* were listed with *M. bauruensis* in Table 5, and those identified as *M. arenaria thamesi* were listed with *M. thamesi* in Table 19.

On the basis of these groupings, there were considerably more weed host entries listed for *M. javanica* than any other nematode species (Table 14). Furthermore, those entries represented more plant families, genera, and species listed as weed hosts of *M. javanica* than for any of the other nematode species. *M. hapla* (Table 11) is in second place, *M. acrita* (Table 1) in third, *M. incognita* (Table 12) in fourth, and *M. arenaria* (Table 3) in fifth place in number of weed host entries, number of species, and number of genera. The order for the number of plant families represented differs in that *M. incognita* is second, *M. acrita* is third, *M. arenaria* is fourth, and *M. hapla* is fifth. In the remaining 14 nematode species, the number of entries in these four categories is appreciably less

than in the five species named.

Turning to a consideration of the weed hosts of the nematodes, the total numbers of host species entries were greatest for the families Leguminosae, with 308; Compositae, with 267; and Gramineae, with 248. Solanaceae ranked fourth, with 155. Then Amaranthaceae, with 89; Labiatae, with 73; Cruciferae, with 62; Malvaceae, with 61; Polygonaceae, with 54; and Euphorbiaceae, with 52 host entries, completes the list of the ten worst host families from the 113 plant families included in this review. These data are a summation from entries in all 20 tables.

The genus *Solanum* had more entries, with 61, than any other, *Amaranthus*, 40; *Trifolium*, 36; *Nicotiana*, 30; *Chenopodium*, 28; *Euphorbia*, 28; *Rumex*, 25; *Hibiscus*, 23; *Ipomoea*, 22; and *Vicia*, 21, completes the list of ten genera with the greatest number of host species entries. These data are also a summation from entries in all 20 tables.

Since plants differ in acceptability as hosts of nematodes, hosts of each of the five species of root-knot nematode previously identified as having the most hosts will be discussed separately. Within each of these sets of entries, there is no duplication of species as occurred in the two previous summations of entries from all 20 tables.

There are 394 species entries of weed hosts of *M. javanica* (Table 14). They are distributed non-uniformly among 227 genera in 64 plant families. The genus *Solanum* had the most host species entries, with 13; *Nicotiana* ranked second, with 8 entries. *Trifolium* and *Amaranthus* each had 7 entries. *Chenopodium*, *Hibiscus*, *Cassia*, *Indigofera*, and *Setaria* each had 6 entries. Note a two-fold spread in number of entries between the first and last named genera.

M. hapla has the second most species entries of weed hosts, with 305 (Table 11). They are also distributed non-uniformly among 173 genera in 48 plant families. In this case, *Rumex* is in first place, with 8 host entries. *Nicotiana* retains second place, with 7 entries. *Solanum* and *Chenopodium* each have 6 species entries. *Trifolium* and *Ipomoea* each have 4 entries. A two-fold spread in number of entries is also noted here between the first and last named genera.

The third most numerous weed host species was for *M. acrita*, with 283 entries in 181 genera and 54 plant families (Table 1). There are 12 host entries for *Trifolium* and 11 for *Solanum*. There are 7 entries for *Amaranthus*, 6 for *Polygonum*, and 5 each for *Hibiscus* and *Eragrostis*.

A spread greater than two-fold is found in this set.

M. incognita, the root-knot nematode species identified as being most widely distributed and causing the most damage to crops worldwide (330), ranks fourth in the number of weed host species (Table 12). There are 252 entries among 164 genera in 59 families. *Amaranthus* heads the list of host genera with 9 species. *Solanum* and *Nicotiana* each have 7 entries. There are 5 entries for each of *Chenopodium* and *Rumex*.

The number of entries for fifth ranking *M. arenaria* is only about 40% of the number of entries for first-ranking *M. javanica* and less than 70% of the number of entries for fourth-ranking *M. incognita*. There are 170 weed host entries in 130 genera of 51 families (Table 3). There are over twice as many entries for the first-ranking genus *Solanum*, with 7, as for the next group. *Amaranthus*, *Nicotiana*, *Hibiscus*, *Ipomoea*, *Indigofera*, and *Digitaria*, each have 3 weed species entries.

It may be deduced from the data presented that many genera, and also families, are represented by only one or two weed host entries. Furthermore, it may be noted that, although the Gramineae ranked third among the plant families in the number of weed host entries, only 3 of the 33 genera identified as being the most frequent hosts were Gramineae. Those three genera were *Eragrostis*, *Digitaria*, and *Setaria*. They ranked lowest in their respective lists. Among the 10 genera identified previously as having the most entries of host species, none were Gramineae. All were dicotyledons. This relates to the fact that dicotyledons are better hosts to most species of *Meloidogyne*. However, differences exist among *Meloidogyne* species. For example, 68% of the host entries for *M. naasi* (Table 17), 57% of the host entries for *M. acronca* (Table 2), 46% of the host entries for *M. microtyla* (Table 16), and all of the few entries for *M. graminicola* (Table 9), *M. graminis* (Table 10), and *M. kikuyensis* (Table 15) are monocotyledons. Similar differences also exist among nematode genera. While dicotyledons are the preferred hosts of *Meloidogyne*, monocotyledons are the preferred hosts of the lesion nematode *Pratylenchus* and some other genera.

A long-standing means of nematode control is crop rotation from susceptible to non-host crops. Nematode populations decrease during the periods of non-host crop culture in the rotation. Length of the intervals between culture of susceptible crops is determined by the time required for nematode populations to diminish below the economic threshold level.

The practice of crop rotation for nematode control is functional if, during the intervals between culture of susceptible crops, weed hosts are not permitted to grow and maintain nematode populations. When weed hosts are permitted to grow, they serve as reservoirs for nematode populations, obviously available to infect susceptible crops whenever they are planted. This negates that purpose of crop rotation.

If used, the weed hosts as pest reservoirs concept might achieve several worthwhile objectives. It might facilitate multidisciplinary research in pest management. This a team would be approach to solution of crop production problems. It might improve the economic aspect of crop production if, by controlling weeds, other pest populations were reduced. This has a multiple advantage in that competition from weeds is reduced concurrent with reduction in populations of the pests they host. It might increase the options among alternative crops which might be grown. The weed hosts as pest reservoirs concept is an example of horizontal integration in pest management.

It seems that much research has been done throughout the world which has not been made accessible to the worldwide scientific community. Much of it has been published only for local use. If a worldwide collaborative network on the weed hosts as pest reservoirs concept were created, it may be possible to disseminate more of this useful information (41). This might be done through regional and multinational conferences, with the proceedings being published. Conference and planning sessions might be used to correlate research as well as to exchange information. Weed scientists and weed science organizations might take a more active leadership role in this multidisciplinary activity. Global and local increases in crop yields and production might be achieved by such a cooperative effort.

The objectives of the weed hosts as pest reservoirs activities are: 1) to emphasize the overall impact of weeds in crop production; 2) to offer another criterion in defining the significance of weeds; and 3) to promote effective control of weeds, thereby reducing their interference with crops and hosting other pests.

This report has presented information on weed hosts of but one significant group of pests -- the root-knot nematodes.

DISCUSSION OF THE PAPERS OF TEM SMITINAND AND L.E. BENDIXEN

(Chaired by K.U. Kim)

Mr. Teoh Cheng Hai (Malaysia): Two questions for Dr. L.E. Bendixen. 1) When assessing the status of weeds as potential reservoirs of nematodes, I find it would be more appropriate to consider the susceptibility of weeds to *Meloidogyne* as well as *Pratylenchus* as both are ubiquitous. 2) If we have a weed and a crop plant of the same genus growing together, which is more likely to be susceptible to nematode infestation?

Dr. L.E. Bendixen (U.S.A.): We have done a rather limited literature search on weed hosts of *Pratylenchus*, the lesion nematodes. Dr. Juliana S. Manuel at the University of the Philippines, Los Banos, is senior author of that publication. We also share authorship of a publication on one of the species of *Heterodera* -- *Heterodera glycines*, the soybean cyst nematode. As I indicated earlier, the three nematode genera of greatest agricultural significance are *Meloidogyne*, *Pratylenchus*, and *Heterodera*, in that order. Because of the magnitude of the literature, I decided to discuss the weed hosts of but one genus.

I choose the root-knot nematodes for several reasons. On a worldwide agricultural basis, they are the most significant. Another impelling reason is that Dr. Joseph N. Sasser at North Carolina State University organized and has directed the International *Meloidogyne* Project for several years. It is a worldwide collaborative network on root-knot nematode biology and control. I felt it would be desirable to review the literature and identify the specific weed hosts of this most important genus of nematodes to facilitate collaborative research between weed scientists and nematologists. Such collaborative research would be desirable because of the expected increase in effectiveness of crop rotations as a means of depleting nematode populations when weed hosts are

controlled concurrently.

The next question is that, if we have host weeds and crops growing together, which one will be the better host. Plants differ in their acceptability as hosts of nematodes. As an example, Dr. R.M. Riedel, nematologist at the Ohio State University, went to Columbia to consult on problems of dry bean (*Phaseolus* sp.) production. The beans used were the best nematode tolerant varieties available. The bean fields were infested with high populations of *Bidens pilosa* which is a better host than *Phaseolus* of the root-knot nematodes. He pulled bean plants out of the ground and drew attention to the nodules of the nitrogen-fixing Rhizobium and galls of the root-knot nematodes. The massive nematode populations procuded on *Bidens pilosa* had overcome the tolerance capacity of the beans. His recommendation was that *Bidens pilosa* must be controlled. The beans would then be able to overcome the nematode problem. To repeat the generalization, plants differ in their acceptability as hosts of nematodes. Whether a crop or a weed is the better host is dependent upon the species being compared.

Dr. J. Harada (Thailand) : To Dr. T. Smitinand. Which types of weeds are more serious in shifting cultivation areas. Naturalized or native species?

Dr. T. Smitinand (Thailand) : I think, the most serious weed is naturalised species.

Dr. M. Nemoto (Japan) : To Dr. T. Smitinand. I would like to ask a question about the difinition of the term, shifting cultivation. It is important to survey the areas in shifting cultivation because I also investigate weed species in shifting cultivation in Thailand.

Dr. T. Smitinand : I guess, shifting cultivation is not permanent. It has been underpractised after cleared the lands or forests of the primary or the secondary ones and then grows crops; after the harvest, moving to another areas, leaving the area to fallow, becoming secondary growth. I say, in Thailand We have two types of shifting cultivation, one is annual being under practised in the highland by the hill tribes. Then rotary one has been under practised by another tribes in the lower elevation.

Dr. K.U. Kim: Dr. T. Smitinand, what is the means used in the shifting cultivation; by hand or rotary? The meaning of shift cultivation is strange to us. First of all, it may be necessary to define the term of shifting cultivation. Then it should be explained what the factors are to induce the shift and why it should happen. Otherwise, it would be difficult to meet the requirement of title.

Dr. T. Smitinand: Shifting cultivation mostly has been done by hand annually, and leaving the land after harvest, but they will return after five or ten years. That makes a rotation.

Dr. M. Blacklow (Australia) : A question for Dr. Bendixen. You provided us with an impressive catalogue of weed-hosts for nematodes. However, if we are to proceed to the horizontal integration of pest management that you advocate, then weed scientists will need to know the nematode density/weed density relationships and the longevity of nematodes in the soil following a given level of weed control in a crop. Can you tell us if such information is available?

Dr. L.E. Bendixen: Your comment is most important. It relates to the time required for a nematode population to decrease below the economic threshold level. There are biological differences among the genera of nematodes. The time will vary from one nematode genus to another. Probably 2 or 3 years may be sufficient for some species of root-knot nematode, while it may take 4 to 6 years for cyst nematodes. However, if the land is not kept free of weed hosts during the non-host cropping time, that is, if a weed population is allowed to exist, the nematode population will be maintained. The time required for nematode populations to diminish below the economic threshold level presupposes a genuine host-free rotation.

Dr. M. Blacklow: Currently our efforts at weed control are determined by the relationships between crop yield and weed density. However, this may not be adequate for the control of nematodes hosted by the weeds. For example, we may be satisfied with a weed density of ten plants per square metre for crop yield but the density of nematodes may not be decreased unless there are less than two weeds per square metre. Have there been any investigations of the relationships between nematode densities and weed densities.

Dr. L.E. Bendixen: My literature search related to the weed hosts of species of root-knot nematodes. It did not include the important question you have raised on the relationship of weed host density and consequent nematode density on crop yield. Therefore, I do not have any literature addressing your question directly. I have indicated that the movement of nematodes is rather random until they come within a couple of centimeters of a root, when their movement becomes directed. The effect of nematodes on crops depends very much on level of infestation. The weed population which might be tolerable as related to competition may not be acceptable as related to hosting nematodes. The example I used of the impact on nematode tolerant beans of the massive populations of nematodes maintained by *Bidens pilosa* gives some clues. Dr. Riedel's conclusion was that if the weed were controlled the nematode tolerance of the beans would be adequate. But there was no indication of an acceptable level of weed population in maintaining nematode populations below a threshold level.

WEEDS AND THE ENVIRONMENT IN THE TROPICS
(Eds. K. NODA & B.L. MERCADO), pp. 173-200, 1986

ALLELOPATHY AND FISH-TOXICITY OF WEEDS

Jiro HARADA

*National Weed Science Research Institute Project, Botany and Weed Science
Division, Department of Agriculture, Bangkok, Bangkok 10900, Thailand*

Abstract. Some plants contain toxic substances, release them into the environment and affect the growth of other plants. This phenomenon is known as an allelopathy. Many allelochemicals have been isolated from various plant species and are reviewed in this paper. Moreover, two researches dealing with *Polygonaceae* weeds and *Oenanthe javanica* are introduced in detail. Some problems on allelopathy in the tropics are also discussed.

Piscicidal plants have been widely used in the world by native tribes or in old times to catch fish. Various types of piscicidal substances have been isolated from these plants and are reviewed in this paper. It was found recently that some aquatic weeds contained piscicidal substances which might affect the aquatic environment. Research on the identification of the piscicidal substance from *Ammannia baccifera*, an aquatic weed is introduced here in detail.

INTRODUCTION

Chemical substances contained in weeds often play an important role as one of the environmental factors which affect the growth of other weeds or crops.

It was found recently that some aquatic weeds contained piscicidal substances which might affect the aquatic environment.

These biologically active substances contained in weeds will be discussed in this paper, mainly based on our own research works.

ALLELOPATHY

Historical Review

Allelopathy as first proposed by Molish in 1937 with higher plants is the production and release of some toxic substances by plants into the environment. As a result, the growth of other plants is affected. Since then, many workers reported this phenomenon with various plants and now allelopathy is extensively used not only in the relations among higher plants but also between higher plants and microorganisms or even among microorganisms (Table 1).

Table 1. Relation between producer of chemicals and sufferer in allelopathy. (Koshimizu, 1978).

Producer	Sufferer	General name
Higher plant	→ Higher plant	kolinc phytotoxin
Higher plant	→ Microorganism	phytoncide phytoalexin
Microorganism	→ Higher plant	marasminc pathotoxin phytotoxin
Microorganism	→ Microorganism	antibiotic

Allelopathy has attracted the interest of not only ecologists but also chemists. Moreover, the rapid development of analytical equipment has made it easier to characterize chemically the substances involved in allelopathy. With such reasons, many allelochemicals have been isolated and identified from various plant species (chemical structures are listed in Fig. 1 with numbers). Volatile monoterpenoids such as camphor (1) and cineole (2) were identified by Muller in 1964 from *Salvia leucophylla* which invades the grassland in California. Crow *et al.* (1971) isolated sesquiterpenes (3, 4, 5) from *Eucalyptus grandis*. Norditerpenelactones such as nagilactone A (6), inumakilactone A (7), ponilactone (8) and podolactone A (9) were isolated from *Podocarpus* spp. These substances are believed to be related to the pure forest formation of *Podocarpus* spp. Bode clarified in 1958 that

1,4,5-trihydroxy naphthalene contained in *Juglans nigera* is oxidized into juglone (10), then inhibits the growth of other plants. 3-acetyl-6-methoxybenzaldehyde (11) was isolated from *Encelia forinosa* (Gray and Bonner, 1948). *Parthenium argentatum* contained *t*-cinnamic acid (12) which was believed to be related to "fairy ring" formation in the community of this plant (Bonner and Galston, 1944). Polyacetylene compound, *cis*-dehydromatricaria ester (13) was isolated from *Solidago altissima*, which possesses a high competitive ability against other weeds and quickly infested all over the non-agricultural area in Japan (Kawazu *et al.*, 1969). Another polyacetylene compounds, matricaria ester (14), lachnophyllum ester (15) and 2-*trans*, 8-*cis*-matricaria ester (16) were isolated from *Erigeron annuus* (Kobayashi *et al.*, 1974). Barley (*Hordeum sativum*) is known as a "smoother crop", which releases toxic substances and inhibits the emergence of weeds. Hordenine (17) and gramin (18) were isolated from barley plants (Overland, 1966). They are believed to be involved in this phenomenon. It is well known that if upland rice plants are cultivated in the same field continuously, the yield decreases year by year. Munakata *et al.* (1959) revealed that the *p*-hydroxycinnamic acid (19) was released from rice plants, accumulated in the soil and reduced rice yield. But in the case of lowland paddy field, irrigation water washes away such substance hence no problem occurs (Above-mentioned example reviewed by Koshimizu, 1978). Red clover (*Trifolium pratense*) is known to cause "clover sickness"; that is, the second crops did not grow well in the field where red clover was cultivated (Tamura *et al.*, 1969). Chang *et al.* (1969) isolated many kinds of isoflavonoids (20-27) from this plant. These substances decompose into phenolcarboxylic acid which causes "clover sickness".

In the old days when shifting cultivation was widely practiced in Japan, farmers cultivated *Perilla frutescense* var. *japonica* for the purpose of reducing the emergence of weeds in the field (Sugawara, 1982). The same species but different variety, *P. frutescense* var. *crispa* is also known to show strong allelopathy. Two plant growth inhibiting substances, perilla ketone (28) and perilla aldehyde (29) were identified from these plants, respectively (Harada, 1984).

Witchweed (*Striga lutea*) is an angiospermous root-parasitic weed indigenous to several tropical and subtropical agricultural areas in the world. Seeds of this plant remain dormant until germination is

stimulated by a chemical produced by the host plant or by certain other plant species. Cook *et al.* (1966, 1972) isolated strigol (30), the stimulant from cotton root exudates and determined its complete structure by X-ray crystallographic analysis of a single crystal. Strigol causes germination of *S. lutea* at concentrations less than 10^{-5} ppm. This substance which shows a promoting effect seems to be very peculiar from the point that most allelochemicals show a plant growth inhibitory activity.

Thus, various types of allelochemicals have been isolated and reported with many plant species. From them, two researches which were carried out by the author's group and published already (Harada and Yano, 1983; Harada, 1986) will be introduced in detail hereafter.

Plant Growth Inhibiting Substance Contained in Polygonaceae Weeds (Example 1)

Family *Polygonaceae* includes important weed species in Japan, such as *Polygonum hydropiper*, *P. japonicum*, *P. conspicuum*, *P. thunbergii*, *P. nipponense*, *P. sagittatum* var. *sieboldii*, etc. in lowlands and *P. longisetum*, *P. lapathifolium* subsp. *japonicus*, *Rumex obtusifolius*, etc. in upland fields (Numata *et al.*, 1975).

These weed species often form a pure community and severely cause weed damage to crops. From such observation, we presumed that these *Polygonaceae* weeds might contain allelochemicals which inhibit the growth of other weeds or crops. These experiments deal with some *Polygonaceae* weed species in Japan and showed the possible existence of plant growth inhibiting substance in these plants.

Plant growth inhibiting activity of the methanolic extracts from 22 *Polygonaceae* weed species was examined by rice seedling bioassay. The results are shown in Fig. 2. Root growth in rice seedlings was strongly inhibited by the extracts from most weeds, while the growth of the second leaf sheath was inhibited by the extracts from some species in higher concentration only. These results clearly showed the existence of plant growth inhibiting substance(s) in *Polygonaceae* weeds.

To identify the substance(s), further experiments were conducted using *P. hydropiper* plants which possess both piscicidal and plant growth inhibiting activities (Harada and Yano, 1983). Preliminary experiments revealed that this substance was extractable with hot

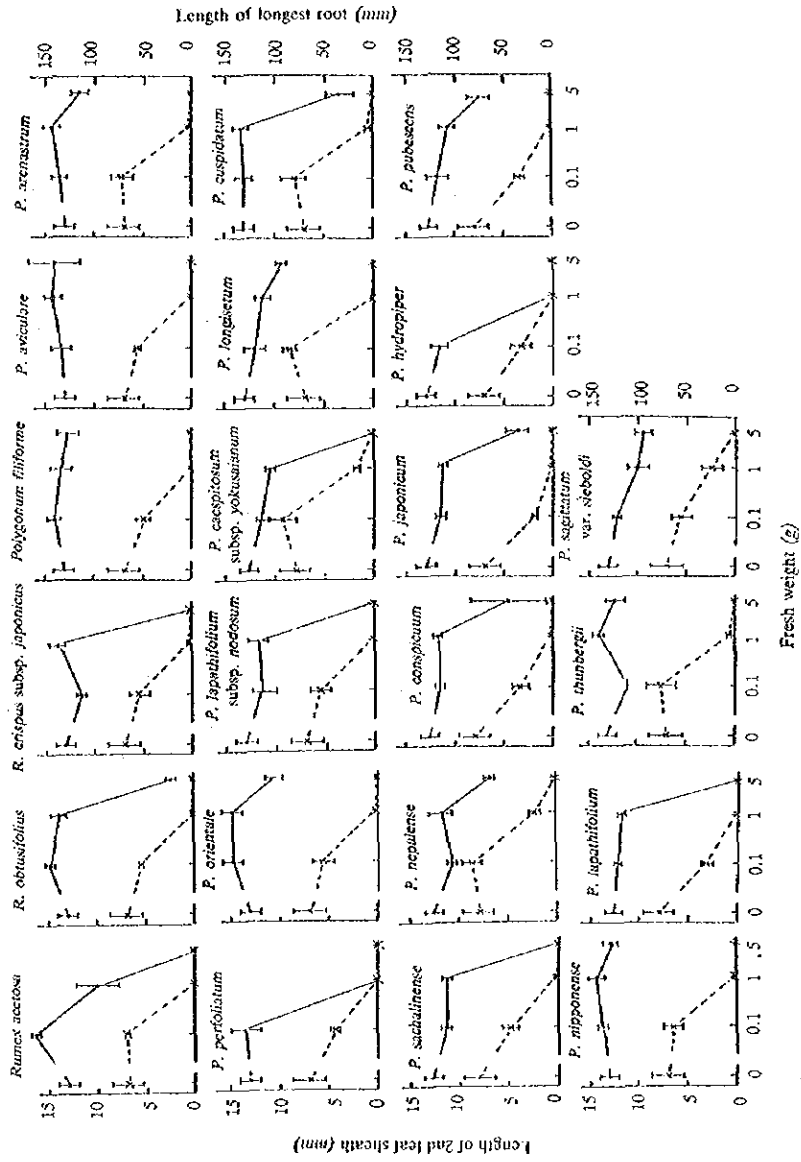

Fig. 2. Effect of the methanolic extracts from 0.1, 1 and 5 g fresh weight of Polygonaceae weeds on the growth of rice seedling cv. Tan-ginbozu (Harada and Yano, 1985).

water, methanol, acetone, ethylacetate, ether, chloroform, benzene or *n*-hexane (Table 2), and easily partitioned from aqueous solution into organic solvent at both pH 3 and 8 (Table 3). From these data, the substance was considered neutral. Methanolic extract was purified by charcoal-celite column chromatography with water/acetone step elution system. Both activities were mainly shown in the same 10/90 (v/v) eluate (Table 4), suggesting that a single substance might possess both biological activities. Biologically active eluate was concentrated in vacuo and further purified by TLC with benzene/ethylacetate (4/1, v/v) solvent system. A single spot at R_f 0.59 was detected as a dark color under UV light and deep yellow color with aldehyde reagent (0.5% 2,4-dinitrophenyl-hydrazine in 2N HCl) spray (Fig. 3). Spotted area was scraped off and eluted with methanol, then biological activity and UV, IR absorbing spectra were determined. It showed a very strong piscicidal and plant growth inhibiting activities and pungency. Also, its spectrum data were as follows: UV $\lambda_{\text{max}}^{\text{MeOH}}$ 228 nm (Fig. 4), IR $\nu_{\text{max}}^{\text{CCl}_4}$ 2700 (-CHO), 1715 (satur. C=O) 1975 (α, β -unsatur. C=O,) 1640 (conj. C=C), 825 ($>=<^{\text{H}}$) cm^{-1} (Fig. 5). From these data, biologically active substance contained in *P. hydropteris* was identified as polygodial (31), which was already reported in the same plant independently of the biological activity (Barnes and Loder, 1962).

To estimate the existence of polygodial in other *Polygonaceae* weeds, piscicidal activity of the methanolic extracts was examined. All the *Polygonaceae* plants showed the activity as shown in Fig. 6. These results suggest that plant growth inhibiting substance contained in *Polygonaceae* weeds is polygodial.

Although roles of polygodial in the growth and allelopathy of *Polygonaceae* weed species are not clarified yet, Sukul (1970) reported that the growth of wheat and the infestation of wheat gall nematode (*Anguina tritici*) were greatly inhibited when they were grown together with *P. hydropteris* and presumed that this inhibition was caused not only by competition for light, water and nutrients but also by toxic root diffusates. A polygodial might be responsible for this phenomenon.

Plant Growth Inhibiting Substance Contained in Oenanthe javanica (Blume) DC. (Example 2)

O. javanica which belongs to family *Umbelliferae* is a serious perennial paddy weed in Japan (Numata *et al.*, 1975). This weed often

forms a pure community in paddy field or paddy levee and severely causes weed damage to rice plants. It is often observed in direct-sown paddy field with heavy infestation of this weed that rice seedlings are extremely retarded in their growth and are not able to emerge from the soil surface. From such observation, we presumed that *O. javanica* plants might contain allelochemicals which inhibit the growth of other weeds or crops. This experiment was initiated to identify the plant growth inhibiting substance contained in *O. javanica* plants.

Effects of the original methanolic extract, n-hexane and aqueous phase of *O. javanica* plants on the growth of rice seedlings were examined and results are shown in Fig. 7. Methanolic extract inhibited sheath growth linearly but it inhibited root growth only at higher concentration. Sheath growth inhibitor(s) was partitioned from aqueous phase into n-hexane phase, however root growth inhibitor(s) remained in aqueous residue. Data indicate that the former substance(s) is less polar than the latter.

Methanolic extract was purified by charcoal-celite column chromatography with water/acetone/ethyl acetate step elution system. As a result (Table 5), root growth inhibiting activity was shown in the first eluate (water/acetone/ethyl acetate, 40/60/0, v/v/v) and sheath growth inhibiting activity was shown in the second and third eluates (20/80/0 and 0/100/0).

The sheath growth inhibitory eluates were combined, concentrated in vacuo, and further purified by TLC with n-hexane/ether (5/1, v/v) solvent system. As a result, four spots at Rf 0.14, 0.22, 0.36 and 0.51 were detected under UV light. Among them, only a substance which

Bioassay: rice seedling cv. Tan-ginbozu

Samples extracted from 1 and 5 g fresh materials were used.

appeared at Rf 0.51 showed a strong growth inhibiting activity (Fig. 8).

To identify the biologically active substance, UV absorption spectrum and GC-MS analysis were carried out. As a result, UV: $\lambda_{\text{max}}^{\text{MeOH}}$ 230, 280 nm (shown in Fig. 9) and fragment peaks of MS: m/e 222 M^+ , 207, 195, 191, 177, 149, 121, 106, 91, 77, 65 (shown in Fig. 10) were obtained respectively. From these data, sheath growth inhibitory substance contained in *O. javanica* was identified as an apiole, 1-allyl-2, 5-dimethoxy-3, 4-methylene dioxybenzene (32).

Recently the author isolated myristicin which possesses a similar chemical structure as apiole from parsley plants (Harada, 1984) and also both myristicin and apiole from parsley seed oil as plant growth regulators (Harada, 1984). By using this isolated apiole from parsley seed oil, effect on the growth of rice seedlings was examined. As shown in Fig. 11, apiole inhibited only leaf sheath growth at lower concentration although it inhibited both sheath and root growth at higher concentration. This characteristic seems to be desirable to consider the practical use of the chemical as a plant growth regulator in agriculture.

One of the plant growth inhibiting substances contained in *O. javanica* was identified as apiole although root growth inhibitory substance remained unknown. Apiole seems to be closely related to allelopathy of this weed species. Further study, however, is essential to clarify the phenomenon.

Problems in the Tropics

The author has described in this paper about two examples of allelopathy researches which were carried out in Japan, a temperate country. In the tropics, however, there are many kinds of weeds showing high competitive ability with other weeds or crops, some of which might be due to allelopathic effects besides the competition for light, water, nutrients, etc. From this point of view, the existence of plant growth inhibiting substances in certain tropical weed species was investigated and reported partially (Fig. 12; Premasthira *et al.*, 1986). Methanolic extracts of most weeds strongly inhibited the rice seedling growth and this clearly indicates the possible existence of plant growth inhibiting substances in the plants, although these substances are not always related to allelopathy. Further investigation and identification of these substances, however, will be a stepping stone to reveal allelopathy. Moreover, mechanical weed control is a popular method in agricultural area of most tropical countries. Generally after eradication weeds are always mixed in the soil as a green manure or

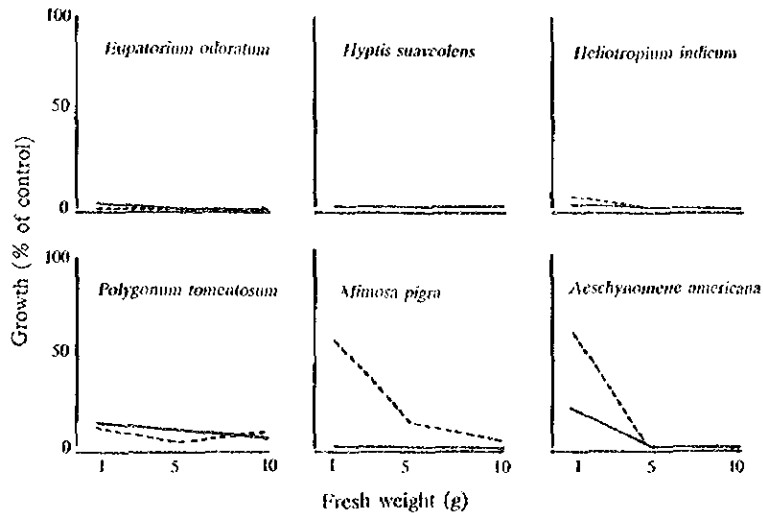

Fig. 12. Effect of the methanolic extracts from 1, 5, and 10 g fresh weight of some weed species on the growth of rice seedlings. (Premasthira *et al.*, 1986).

Broken line: 2nd leaf sheath, Solid line: root

sometimes weeds are dried and mixed in the soil during land preparation. Horowitz and Friedman (1971) revealed that fresh or dried plant material can produce toxic substance during their decomposition. From this point of view, we must avoid to incorporate weeds which contain strong plant growth inhibiting substances, into the soil.

Further researches are under way through the cooperation between Thai and Japanese researchers in the National Weed Science Research Institute Project.

FISH-TOXICITY OF WEEDS

Piscicidal Plants

Piscicidal plants have been widely used in the world to catch fish in old

times or by native tribes at present. From these plants, various types of piscicidal substances have been isolated and reported (Fig. 13 with numbers). Rotenone (33) was isolated from *Derris elliptica*, *D. montana* or *D. pubipetala* (belong to *Leguminosae*), root of which were widely used in Southeast Asia, juglone (5-hydroxynaphthoquinone) (34) from *Juglans mandshurica* (*Juglandaceae*), roots or fruits of which were used in Japan, justicidin A (35) and B (36) from *Justicia hayatai* var. *decumbens* (*Acanthaceae*), whole plants were used in Taiwan (Ohta *et al.*, 1969, 1971), Callicarpone (37) from *Callicarpa candicans* (*Verbenaceae*), leaves of which were used in Caroline and Philippine islands, maingayic acid (38) from *Callicarpa maingayi* (*Verbenaceae*) (Nishino *et al.*, 1971), huratoxin (39) from *Hura crepitans* (*Euphorbiaceae*), latex of which was used in South America (Sakata *et al.*, 1971), vibsanine A (40) from *Viburnum awabuki* (*Caprifoliaceae*), leaves of which were used in Okinawa, Japan (Kawazu and Mitsui, 1974), inophyllolide (41) from *Calophyllum inophyllum* (*Guttiferae*), leaves or seeds of which were used in Malay peninsula, ichthyothereol (42) from *Ichthyothere terminalis* (*Compositae*), leaves of which were used in the Amazon (Reports without citation: reviewed by Kawazu, 1972). The plants mentioned show a very strong piscicidal activity but seem to possess no possibility to pollute the aquatic environment because most of them grow far from the area.

Piscicidal Aquatic Weeds

Recently it was found and earlier mentioned in this paper that *P. hydropiper*, a weed in aquatic environment contained polygodial which shows a strong piscicidal activity (Harada and Yano, 1983). However, we were not aware of the importance of this fact, because aquatic environment such as rivers, lakes or paddy fields are well polluted in Japan with a large amount of agrochemicals and exhausts from factories or houses. In most Southeast Asian countries, aquatic environment is very important as a site of protein production. Farmers control aquatic weeds by plowing and flooding the land, where fish culture is commonly practiced. In addition, large number of fish often die with unknown cause in the area, although no agrochemical has been used at all.

From these facts, we considered that piscicidal substances contained in aquatic weeds might be related to the cause of fish killing. Hence, we examined the piscicidal activity of 54 weed species grown in tropical

Fig. 13. Chemical structures of piscicidal substances isolated from plants.

aquatic environment with guppy fish and found that twelve species among them showed the activity as shown in Table 6 (Zungsonthiporn *et al.*, unpublished).

Table 6. Piscicidal weeds grown in aquatic environment (Zungsonthiporn *et al.*, unpublished).

Weed Species	Family
<i>Ammannia baccifera</i>	<i>Lythraceae</i>
<i>Polygonum tomentosum</i>	<i>Polygonaceae</i>
<i>Dysophylla stellata</i>	<i>Labiatae</i>
<i>Sphenoclea zeylanica</i>	<i>Sphenocleaceae</i>
<i>Bacopa monnieri</i>	<i>Scrophulariaceae</i>
<i>Mimosa pigra</i>	<i>Mimosaceae</i>
<i>Neptunia natans</i>	<i>Mimosaceae</i>
<i>Sesbania javanica</i>	<i>Papilionaceae</i>
<i>Ipomoea aquatica</i>	<i>Convolvulaceae</i>
<i>Centrostachys aquatica</i>	<i>Amaranthaceae</i>
<i>Potamogeton malainus</i>	<i>Potamogetonaceae</i>
<i>Pistia stratiotes</i>	<i>Araceae</i>

Piscicidal substance(s) was extracted from shoots of *Ammannia baccifera* which showed the strongest activity with various solvents (Table 7). Most extracts except water showed strong activity. It is clearly understood that the active substance(s) is widely soluble in non-polar to polar organic solvents. Methanol extract, however, killed

Table 7. Piscicidal activity of various extracts from 0.1, 0.5 and 1.0 g fresh weight of *Ammannia baccifera* shoots (Zungsonthiporn *et al.*, 1986).

Solvent	Mortality (%)		
	0.1	0.5	1.0
Cold water	0	0	0
Hot water (80° C)	0	0	20
Methanol	100	100	100
Ethyl acetate	100	100	100
Benzene	100	100	100
n-Hexane	100	100	100

the fish earlier than the other extracts. Hence we used methanol for extraction thereafter.

Purification of the active substance(s) was carried out by a charcoal-celite column chromatography with water/acetone step elution system. As a result, the active substance(s) came out in 0/100 (water/acetone, v/v) fraction. One g (equivalent to fresh material) of the active fraction was developed on TLC plate with n-hexane/ethylacetate mixture (9/1, v/v). The dark violet band was found at Rf 0.65 under UV light as shown in Fig. 14. This zone was scraped off and eluted with methanol for piscicidal activity and further analysis. The substance(s) at Rf 0.65 apparently showed a strong piscicidal activity.

Fig. 14. Thin layer chromatogram of the active fraction from charcoal-celite column chromatography (Zungsonthiporn *et al.*, 1986).

Silica gel plate --- Whatman LK 6, 5×20 cm

Developing solvent -- n-Hexane : Ethyl acetate 9:1 (v/v)

UV-absorption spectrum of the active zone is shown in Fig. 15. λ max in methanol was 244 nm. The pattern resembled to that of α -naphthoquinone. GC and GC-MS analyses, however, were carried out for identification of the substance.

Fig. 15. UV-absorption spectrum of methanol solution of piscicidal substance isolated from *Ammannia baccifera* (Zungsonthiporn *et al.*, 1986).

GC pattern is shown in Fig. 16. The active zone gave three peaks, one major and two minor. Mass spectrogram of major substance (A) gave fragment peaks; $158M^+$, 130, 104, 102, 76 as shown in Fig. 17. Fragment peaks of the first (B) and the second (C) minor substances were $174M^+$, 158, 146, 130, 118, 105, 102, 89, 76, and $188M^+$, 174, 158, 130, 116, 102, 89, 76, respectively. From the results, major active substance contained in *A. baccifera* was identified as α -naphthoquinone (43). Two minor substances, however, still remain unknown.

To ascertain the activity, piscicidal effect of synthetic α -naphthoquinone was examined by using guppy. As a result (Fig. 18), TLM (24 h) was about 0.09 ppm. This value is just moderate compared with other piscicidal substances; *i.e.* huratoxin : 0.0014, justicidin A and B : 0.02 and 0.04, callicarpone : 0.04, vjbsanine : 0.1, cis-dehydromatricaria ester : 2, maingayic acid : 4.7 and inophyllolide : 5 ppm (reviewed by Kawazu, 1972).

Fig. 16 Gas-chromatogram of active fraction from TLC (Zungsonthiporn *et al.*, 1986).
 Column : 25 m L, 0.2 mm I.D.
 Temp : 100 - 280°C (6°C/min)
 Liquid phase : 5% phenylmethyl silicone
 Carrier Gas : He.
 Flow rate : 50 ml/min, column 0.5 ml/min
 Vent : 50 ml/min, split ratio : 1:100

Fig. 17. Mass spectrogram of piscicidal substance isolated from *Ammannia baccifera* (Zungsonthiporn *et al.*, 1986).

Fig. 18. Effect of synthetic α -naphthoquinone to the guppy fish (Zangsonthiporn *et al.*, 1986).

Quantitative analysis by using UV absorption spectrum revealed that 1.0 g fresh weight of *A. baccifera* shoots contained 78 μ g of α -naphthoquinone. From this point, an enough amount of pollutant can be found in aquatic environment all over the country.

Our field observation in Buri Ram, Surin and Si Sa Ket, Northeastern Thailand on December 11 to 13, 1984 revealed that heavy proliferation of piscicidal aquatic weeds as well as *A. baccifera* was found in the area where large number of fish died. Further studies, however, are essential to clarify the relation between piscicidal aquatic weeds and the cause of fish killing in natural condition.

CONCLUSION

Isolation and identification of allelochemicals or piscicidal substances from weeds seem to be very important not only to reveal allelopathy or environmental pollution but also to find new biologically active substances for future practical use. Such interest must be focused in the tropics where abundant plant resources exist.

HERBICIDES IN THE ENVIRONMENT

Y.L. CHIEN and H. NAKAYAMA

Department of Agricultural Chemistry, National Taiwan University, Taipei, Taiwan, Republic of China and The Institute of Physical and Chemical Research, Wako, Saitama, Japan

Abstract. Herbicides play a very important role in modern agriculture. In spite of some significant advantages in the use of herbicides, they also have several important disadvantages that must be considered carefully when these herbicides are applied in the fields. In this paper, fate and behavior of herbicides in the environment after their application are reviewed particularly with herbicides currently used in Taiwan and in Japan. Emphases are made on the herbicides used in paddy fields, because rice is a big crop ranking second to wheat in terms of area harvested, and is mainly cultivated in Asian countries by the method of transplanting in paddy fields. The flooded soil is characteristically different from non-flooded soil in its physical, chemical and microbiological properties. Therefore, the fate, dissipation and mechanism of degradation of herbicides applied to the paddy fields may differ from those in non-flooded soils. Many factors may affect the behavior and fate of herbicides after their application. Climatic conditions and soil properties seem to be critical.

The present review is primarily concerned with recent progress on the herbicides in the environments after their use. Studies with the rice paddy model ecosystem, which seemed to be very effective and useful for studying the fate of herbicides in the environment are also included.

HERBICIDES USED IN PADDY FIELDS

At present time, 89 kinds of herbicides with different chemical structures have been registered in Taiwan. Of these chemicals, 25 compounds were used in paddy fields either as a single component or as component(s) in the mixed herbicides (Table 1). Besides these herbicides, additional 14

Table 1. Herbicides registered for use in paddy fields in Taiwan and in Japan.

Common name	Chemical name	Year registered	
		Taiwan	Japan
Dichlobenil (DBN)	2,6-Dichlorobenzonitrile	1965	1963
Propanil (DCPA)	N-(3,4-Dichlorophenyl) propanamide	1966	1961
Molinate	S-Ethyl-N,N-hexamethylene thioicarbamate	1967	1972
MCPA*	2-Methyl-4-chlorophenoxyacetic acid	1970	1953
Chloritrofen (CNF)	2,4,6-Trichlorophenyl-4'-nitrophenylether	1970	1963
Benthiocarb (Thiobencarb)	S-(4-Chlorobenzyl)N,N-diethylthiocarbamate	1971	1969
Butachlor	N-(Butoxymethyl)-2-chloro-2',6'-diethylacetanilide	1971	1973
Credazine*	3-(2-Methylphenoxy) pyridazine	1971	1971
Chlomethoxymil	2,4-Dichlorophenyl 3-methoxy-4-nitrophenylether	1972	1973
Oxadiazon	2- <i>tert</i> -Butyl-4-(2,4-dichloro-5-isopropoxyphenyl)-2',1,3,4-oxadiazolin-5-one	1972	1972
Phenopylate	2,4-Dichlorophenyl-1-pyrrolidinedecarboxylate	1973	1977***
Piperophos*	S-(2-Methyl-1-piperidylcarboxymethyl)-O,O-di-n-propylphosphorodithioate	1974	1976
Dimethametryn*	2-(1-2-Dimethylpropylamino-4-ethyl-amino-6-methyl-thio-s-triazine	1974	1976
Methoxyphenone	3,3'-Dimethyl-4-methoxybenzophenone	1976	1976
Bensulide (SAP)*	S-(O,O-Diisopropyl phosphorothioate) ester of N-(2-mercaptoethyl) benzene sulfonamide	1976	1982
Bifenox	Methyl 5-(2,4-dichlorophenoxy)-2-nitrobenzoate	1976	1982
Trifluralin*	α, α, α -Trifluoro-2,6-dinitro-N,N-dipropyl-p-toluidine	1976	1970

Table 1. (continued)

Common name	Chemical name	Year registered	
		Taiwan	Japan
Bentazone	3-Isopropyl-1H-2,1,3-benzothiazin-4(3H)-one 2,2-dioxide	1976	1975
Pendimethalin	N-(1-Ethylpropyl)-3,4-dimethyl-2,6-dinitrobenzenamine	1976	—**
Napronamide*	α -(β -Naphthoxy) propionanilide	1976	1980
Fluothuron (Thiochloromethyl)	3-(4-Difluorochloromethylmercapto-3-chlorophenyl)-1,1-dimethylurea	1977	1979***
Dymron*	1-(α , α -Dimethylbenzyl)-3-(4-methylphenyl) urea	1979	1975
Oxyflufen*	2-Chloro-1-(3-ethoxy-4-nitrophenoxy)-4-(trifluoromethyl) benzene	1980	—**
Trichlopyr*	[(3,5,6-Trichloro-2-pyridinyl)oxy] acetic acid	1982	—**
Bromobutide*	N-(α , α -Dimethylbenzyl)- α -bromo-tert-butyl acetanilide	1983	—**

* Used as a component of mixed herbicide only.

** Not registered for use in paddy fields in Japan.

*** In the year registration was withdrawn in Japan.

different chemicals have been also registered as herbicides for use in paddy fields in Japan (Table 2).

Although the method of cultivation of rice in paddy fields is pretty close between Taiwan and Japan, owing to the quite different climatic conditions and cultivation system, herbicides used for the control of weeds in paddy fields are not always be quite the same. For example, Taiwan located in the tropical and subtropical zones, but Japan in temperate zones. Moreover, rice is cultivated once a year in Japan but it is two crops in Taiwan. Soil properties and weed flora are also different somewhat in detail. From these reasons, some herbicides such as simetryn and several phenoxy-type compounds which are very popular in Japan, could not be used in Taiwan because these herbicides are very sensitive to temperature. Simetryn alone or combined with other herbicides such as benthocarb, MCPB, molinate, phenothiol, bentazone, bensulfide, ACN or methoxyphenone are officially registered in Japan for control of weeds in paddy fields. But serious injuries to rice were found even after the rate of simetryn was reduced to minimum amounts when these combined herbicides were tested in Taiwan. Other examples are the phenoxy-type herbicides such as 2,4-D, MCPA, MCPB and their salts or esters which were extensively used in Japan. Because of the unusual low temperature in early spring in southern part of Taiwan, occasional cases of injury to rice like onion-leaf phenomenon were observed in the first crops at the temperature of below 15°C when these herbicides alone or mixed herbicides containing these phenoxy-type compounds were used. Another case is benthocarb. Dwarfing of rice plants in the paddy field by the application of benthocarb, especially under the reductive soil conditions with a larger amount of organic substances such as raw straws, was widely reported everywhere in Japan since 1976. *S*-Benzyl *N*, *N*-diethylthiocarbamate, the dechlorination product of benthocarb, found to be associated with the phytotoxic action and believed to be the cause of the dwarfing of rice plants, was identified from the soil of paddy field by Ishikawa *et al.* (1980). Neither the dechlorination of benthocarb nor the degradation of dechlorinated benthocarb occurred in the sterilized soil, indicating that soil microbes were involved in this dechlorination reaction (Tatsuyama *et al.*, 1981). Properties and conditions of soils causing the dechlorination of benthocarb in flooded soils were carefully examined in the laboratory by Moon and Kuwatsuka (1984, 1985). But dwarfing of rice plants in

Table 2. Herbicides registered for use in paddy fields in Japan but not in Taiwan.

Common name	Chemical name	Year registered
2,4-D (Sodium salt) (2,4-PA)	Sodium (2,4-dichlorophenoxy) acetate	1950
2,4-D (Ethyl ester)	Ethyl (2,4-dichlorophenoxy) acetate	1957
PCP (Sodium salt)	Sodium pentachlorophenolate	1957
MCP (Ethyl ester)	Ethyl 2-methyl-4-chlorophenoxyacetate	1957
MCPB (Ethyl ester)	Ethyl 4(4-chloro-2-methylphenoxy) butylate	1959
Allyl MCP	Allyl 2-methyl-4-chlorophenoxyacetate	1961
Prometryn	2,4-Bis (isopropylamino)-6-(methylthio)-s-triazine	1963
Chlorthiamid (DCBN)	2,6-Dichlorothio benzamide	1964
Swep (MCC)	Methyl-N-(3,4-dichlorophenyl) carbamate	1966
2,4-D (Amine salt)	Dimethylamine salt of (2,4-dichlorophenoxy) acetic acid	1967
ACN	3-Chloro-2-amino-1,4-naphthoquinone	1968
Simetryn	2,4-Bis-(ethylamino)-6-methylthio-s-triazine	1969
Phenothiol*	S-Ethyl-4-chloro-2-methylphenoxythioacetate	1971
Pyrazolate	4-(2,4-Dichlorobenzoyl) 1, 3-dimethyl-5-pyrazolyl- <i>p</i> -toluene-sulphonate	1980

*Used as a component of mixed herbicide only.

the paddy fields, by the application of benthocarb, was never reported in Taiwan so far probably due to the different cultivating systems and difference in the climatic condition and soil properties.

Several review papers concerning the herbicides and the environment were published. Environmental problems related to herbicidal use in Japan were reviewed by Matsunaka and Kuwatsuka (1975). The fate and behavior of herbicides in the soil environment, with special emphasis on the fate of principal paddy herbicides in flooded soils in Japan were reviewed by Kuwatsuka and Niki (1976). Kuwatsuka (1983) also reviewed the fate of herbicides in flooded paddy soils. The effects of temperature, photodecomposition, microbial degradation, and soil properties on the herbicides used in paddy fields and effects of some herbicides on fish, mussel, seaweed, and *Chlorella* were reviewed by Chen (1983). Chen (1983) also reviewed the behavior and fate of pesticides in paddy ecosystems in which 17 herbicides used in paddy fields were included. Recently, residue problems of herbicides in paddy fields and aquatic environments were reviewed by Yamada (1985).

FACTORS AFFECTING DEGRADATION OF HERBICIDES

Many factors may affect the behavior and fate of herbicides after their application in the environment. Undoubtedly almost all of herbicides are applied to the soils. Even with a foliage spray, a great majority of the herbicides will fall to the soils eventually. Thus, interactions between herbicides and soils are indispensable. All herbicides decompose and metabolize in soils to a varying degree. The extent and nature of the degradation vary with environmental conditions and chemicals. Certain herbicides are metabolized or degraded completely in a matter of hours, but on the contrary, other chemicals require weeks or months. Moreover, some complex herbicides are readily metabolized by soil microbes, while some relatively simple ones are amazingly resistant to biodegradation. Of course, a great majority of degradation results from biotransformation by different enzymatic actions by soil microbes, but a minor degradation may also take place by normal chemical reactions.

Minor change of the chemical structure may change the nature and effect in the environment. For example, butachlor differs from alachlor only by butyl group instead of methyl group. Butachlor is one of the

most popular herbicides used in paddy fields, but alachlor is only used in the upland crops. Sodium salt of 2,4-D and esters of 2,4-D are quite different in their volatility. Thus, the effects of these compounds to the environment will be different too. The amount of herbicide residues that can accumulate in soils depends on factors such as the nature of the chemical, soil type and texture, moisture, soil microbes, cation exchange capacity, content and nature of organic matter and clay minerals, pH of the soil and so on. Photodecomposition is also an important phenomenon related to residue dissipation.

Some factors related to the degradation and dissipation of herbicides after application include temperature, photodecomposition, microbial degradation, and soil properties.

Temperature

Some herbicides such as simetryn and the phenoxy-type herbicides are very sensitive to temperature as they were already mentioned before.

In laboratory tests by Chen and Chen (1979), the volatilization of butachlor from aqueous solution and its adsorption in soils were significantly influenced by temperature. The loss of butachlor by volatilization from 0.05 M CaCl₂ solution was demonstrated to be 4.5% at 21.5°C (room temperature), and 30% at 40°C. Raising the temperature from 20 to 40°C resulted in decreased adsorption by soils.

In field experiments, some differences were observed between the first crop (March) and the second crop (August). Degradation and dissipation of butachlor were more rapid in the second crop (Table 3) (Chen and Chen, 1979).

Although simazine [2-chloro-4, 6-bis (ethylamino)-s-triazine] is not used in paddy fields, in the collaborative experiment on simazine persistence in soils initiated by the European Weed Research Society (EWRS) (Walker *et al.* 1983) the effects of soil temperature and soil moisture content on the rate of simazine degradation were measured in the laboratory in soils from 21 sites located in 11 countries. First-order half-lives under standard incubation conditions were significantly correlated with clay content, organic carbon content and soil pH in a multiple linear regression. The temperature dependence of degradation was similar in the different soils whereas the moisture dependence showed considerable variation between soils.

The field experiments performed in Taiwan by Chen *et al.* (1983) with

Taichung clay loam in different seasons and Taipei loam soils showed a significant difference between climate and degradation rate. Simazine had a half-life of 18 days in the summer which is relatively hot and wet, a half-life of 24 days in the cooler and dryer winter season of the Taichung area, but in the medium temperature and medium precipitation of the autumn season of the Taipei area, the half-life was found to be 14 days (Table 4).

These results indicate that climate was not the only factor affecting degradation of simazine, but soil properties may also be related to the degradation rate. Laboratory studies of degradation rates performed with 3 different temperatures at soil moisture content of 90% field capacity and 4 different soil moisture contents at 20°C on different types of soil texture showed a significant relationship between the temperature and the residues of simazine in soils, and also a positive tendency was observed between soil moisture content and degradation (Table 5) (Walker *et al.*, 1983)

Photodecomposition

Photodecomposition is an important route of degradation and dissipation of herbicides from crops and soils. Such studies are useful in establishing residue tolerance and residue levels considered to be negligible. These studies are also important in establishing non-effect levels and waiting periods for crops. Butachlor was photodecomposed rapidly under UV light as a thin film on glass. The half-life was found to be about 1.5 hr. At least 7 photodecomposition products were observed (Chen and Chen, 1978). Photodecomposition of butachlor in aqueous solution was very fast and more complicated than that as a thin film on a glass surface. The half-lives were demonstrated to be about 0.8 hr. under UV light and 5.4 hr. under sunlight irradiation, respectively. As many as 24 compounds were detected and the partial pathways involved in the photodecomposition in aqueous solution was proposed (Chen *et al.*, 1982).

Among the herbicides used in paddy fields, photodecomposition of many compounds were already investigated. These herbicides include PCP (Kawahara *et al.*, 1965, 1966, 1969), benthioecarb (Chen *et al.*, 1976, Ishikawa *et al.*, 1977, Ishikawa *et al.*, 1980), bifenox (Ohyama and Kuwatsuka, 1976), molinate (Soderquist *et al.*, 1977), credazine (Nakagawa and Tamari, 1974), propanil (Moilanen and Crosby, 1972), methoxyphenone (Fujii *et al.*, 1979), bentazone (Nilles and Zabik, 1975)

and bromobutide (Takahashi *et al.*, 1985).

Microbial Degradation

Soil microbes undoubtedly play a very important role in the degradation and dissipation of herbicides in soils. Microbial decomposition was proved to be the major avenue of dissipation of butachlor from soils (Beestman and Demming, 1974). Several soil microbes effectively degraded butachlor. Some of the metabolites by a soil microbe *Mucor sufui* NTU-358 were identified and the pathways involved in the degradation of butachlor were proposed (Chen and Wu, 1978). Degradation of butachlor by a soil fungus *Chaetomium globosum* was also studied. More than 10 metabolites were isolated and some of these were characterized (Lee, 1978). About 20 metabolites were detected from the degradation products of benthicarb by soil microbes (Ishikawa *et al.*, 1976).

Microbial degradation can be rapid and complete. For example, 2,4-D is degraded completely to CO₂, H₂O and chlorine, and has an average half-life in paddy field of only several weeks. Half-lives of the herbicides used in paddy fields in Japan are shown in Table 6 (Kuwatsuka, 1983).

Degradation of some herbicides in soils used in paddy fields were also reported. These herbicides included PCP (Kuwatsuka and Igarashi, 1975), bifenox (Ohya and Kuwatsuka, 1976, 1978, 1983), chlornitrofen (Niki and Kuwatsuka, 1976, Oyamada and Kuwatsuka, 1979, Yamada, 1983, Yamada and Suzuki, 1983), chlomethoxynil (Niki and Kuwatsuka, 1976), molinate (Inai and Kuwatsuka, 1982), naproanilide (Oyamada *et al.*, 1980), methoxyphenone (Izawa and Asaka, 1979, Izawa *et al.*, 1981, Kurozumi *et al.*, 1980), simetryn (Izawa *et al.*, 1981) and MCPB-ethyl (Asaka and Izawa, 1982, Izawa *et al.*, 1981).

Populations of fungi, actinomycetes and bacteria increased 1 week after the addition of butachlor to the soil. Higher doses of butachlor kept the population of soil microbes higher than that in the control up to 4 weeks after incubation (Chen *et al.*, 1981). The effect of PCP on bacterial flora in reductive layers of water-logged soil was studied. PCP was applied to the surface water of water-logged soil at the recommended rate and at 100 times the recommended rate. Changes in total numbers of aerobic bacteria were not clear. However, the effects on the changes

in numbers of PCP-tolerant bacteria and gram-negative bacteria were clear (Kato *et al.*, 1981).

Table 6. Half-lives(days) of paddy herbicides in flooded soils*.

Herbicide	In laboratory experiments**	In paddy fields***
2,4-D	30-40	35,48
2,4-D ethyl	< 1 hr	
MCPA	3, 4, 7, 7, 15, 20	7, 7
MCPA ethyl	7-14	
Phenothiol	< 1	< 5
PCP	5, 10-17, 12-70 (average 30), 60	3-4, 6-7, 10-17
Benthiocarb	7-100 (average 40)	3-8, 7, 8, 14, 62
Molinate	7, 15, 18, 30	< 1, < 5, < 5, < 5, < 9, 11
Swep	2-9, 10-14, 7-14	< 10
Propanil	< 1-1, 1, < 5	< 1-1
Naproanilide	5, 6	2, < 4, 4
Butachlor	9-30	6, 8
Credazin	90-150	22, 45
Trifluralin	9, 10, 22, 45	10, 45
Chlornitrofen	7-35 (average 15), 17, 35	7, 9, 12, 13, ca. 14
Chlormethoxynil	7-35 (average 15), 30	7-8
Bifenox	4, 4	4, 4
Oxadiazon	75, 93-98	
Bentazone	5, 33, 45	15, 15
Simetryn	< 37, 63	
Prometryn	100, 120	

* Data were collected from various sources.

** Each chemical was mixed with soil and incubated at 25-30°C in dark.

*** Persistence in soils in paddy fields in Japan. Most herbicides were applied in May or June.

STUDIES WITH RICE PADDY MODEL ECOSYSTEM

The rice paddy model ecosystem, replacing the original sorghum plant by rice seedling with other biota unchanges, was introduced by Lee *et al.*, (1976). The fate of three diphenyl ether-type herbicides, nitrofen, chlormethoxynil, and bifenox was studied by this system. Nitrofen was

found to be relatively stable under the model ecosystem. It was bioconcentrated and stored over a 33-day period in the tissues of alga, snail, mosquito larva, and fish. When the carbomethoxy group of bifenox was used as a degradophore, tissue storage of the parent compound was minimal. The methoxy group of chlomethoxynil was not an effective degradophore. This system was further modified by substituting the organisms involved in food chains to fit an actual rice paddy field condition in Taiwan. The environmental fate of benthicarb was studied with this system (Chen *et al.*, 1982). With their low ecological magnification values and high biodegradability indices, the use of benthicarb in paddy field was found to be very safe. This rice paddy model ecosystem seemed to be very effective and useful for studying the environmental fate of pesticides especially those to be used in rice paddy fields.

CONCLUSION

It is not the intention of the authors to review all of the literatures on the behavior of herbicides in the environment. Emphases are made on the herbicides used in paddy fields because rice is mainly cultivated in Asian countries by the method of transplanting in paddy fields. In fact, more than one half of the population in the world is consuming rice as their staple food. The consumption of herbicides is still increasing year by year. Although the herbicides currently used are relatively non-persistent, and with rather low mammalian toxicities in general, the effects of these chemicals, which has been produced only by man, on the environment should be carefully considered before their application. More attention should be paid on the environmental quality. It is our responsibility to prevent possible pollution from our environment which might be occurred by the misuse of these herbicides.

DISCUSSION OF THE PAPERS OF J. HARADA AND Y.L. CHEN

(Chaired by B.L. Mercado)

Dr. M. Blacklow (Australia) : To Dr. J. Harada, a question of terminology. You showed a classification of allelopathy that operated at the level of higher plants and below. However, you discussed plant chemicals that were piscicidal and you also showed chemicals extracted from red clovers (*T. pratense*) that are precursors of oestrogens that cause reproduction problems in sheep. Do you suggest that we expand allelopathy to include effects on higher organisms, even drugs used by man?

Dr. J. Harada (Thailand): I can't answer. I think it maybe changed year by year as situations change. The effect on fishes and animals should be called allelopathy in future.

Mr. David T.K. Wang (Taiwan, ROC): Dr. Y.L. Chen, regarding the herbicides, a herbicide is used in granular type. This granular type is anything reflected or effected by the soil of flooded rice or its physical and/or chemical properties of the soil?

Dr. B.L. Mercado: Is your question the relation of soil properties and herbicide degradation?

Dr. Y.L. Chen (Taiwan, ROC) : Of course, the soil properties affect herbicide degradation in the environment. But I think herbicides may not affect so much the soil properties.

Dr. Somchai Khomvilai (Thailand): Dr. Chen, why do you use % F.C. instead of moisture content? Because the moisture content of F.C. will change with soil texture, e.g. the clay soil will have high moisture

content at F.C. than the sandy soil.

Dr. Y.L. Chen: It is true. Because this collaborative work was designed by European Weed Research Society. We just follow their method. The detail of data will be shown in the proceeding of the Symposium.

Dr. M. Blacklow: Dr. J. Harada, you showed us an impressive range of chemical structures you extracted from a wide range of plants that were allelopathic in the rice seedling bioassay. However, to be of ecological significance those chemicals need to be released and persist in the environments. Do you consider all of the compounds you showed us are likely to be of ecological significance?

Dr. J. Harada : I don't have enough data at the laboratory level, but we can find such phenomena in the field. We can presume that some chemicals from roots, or dead plant materials, will appear in the soil, although I didn't examine this on all the substances. But we grew some plants in water culture mixed with active carbon. After some days, substances adsorbed by the active carbon were eluted and identified. We could find some inhibitory substances.

Dr. B.L. Mercado: Dr. Y.L. Chen, as for herbicides in rice, does either a granular type or any other type affect the properties of soils?

Dr. Y.L. Chen: I am sure that the soil property does not change so much by the use of different type of herbicides, but a granule type is popular. Different processing of granular preparation will give some different effects on the effectiveness because of being slowly or fastly released.

Dr. Lii-Sin Leu (Taiwan, ROC): Dr. Harada, I wonder if any chemicals secreted or produced by weeds are beneficial to the growth of crop plants.

Dr. M. Soerjani (Indonesia) : With regard to the question whether allelopathic substances are also released from the leaves, *Juglans nigra* releases hydroxyjuglone from the leaves and oxydised in the air to become juglone which has an inhibiting capacity to nearby plants. Recent work, e.g. of Eussen in Indonesia and others showed that *Imperata cylindrica* also releases allelopathic substances (the phenolic compounds)

from the leaves, both from the intact leaves as well as from dead leaves. There are also allelopathic substances released to stimulate the growth of other plants. For instance, the release of strigol by host plants of *Striga lutea* which stimulate the germination of striga seeds.

Dr. J. Harada : I think, corn, sorghum or any other host plants produce strigol. It was originally identified in cotton plants, and stimulates the seed germination of *Striga*. It is very rare case.

GENERAL DISCUSSION

(Chaired by B.L. Mercado)

Dr. S. Matsunaka (Japan) : I will talk about air pollution, another viewpoint of the symposium titled "Weeds and the Environment in the Tropics". Air pollution is an important environmental problem even in the developing countries. I felt some smell of ozone, a component of photochemical oxidants in Bangkok. In a highly crowded city you may face the air pollution problem soon. In the case of such pollution, herbicide researchers can contribute to manage this problem. One point is to estimate the injury of these pollutants to the crop plants. Another is the utilization of indicator plants to estimate how the states of air pollutions are with a lot of higher plants including weeds themselves. In this case the idea of selectivity mechanism of herbicides is very important. So, air pollution is one kind of environmental problems to which we, weed scientists, can contribute. I have published already two books related to the indicator plants for air pollution in Japan.

Another is related to the sleeping sickness. It is called Japanese encephalitis caused by virus which is mediated by mosquito born in the paddy fields. By the statistics the usage of diphenylether herbicides such as nitrofen or chloronitrofen in the paddy fields and the number of patients of this sickness in Japan have a close negative correlation each other. These diphenylether herbicides can kill mosquito larvae at the practical dosage even though these are useful for the safety to fish. These mosquito larvae killers were applied just after transplanting. At this time overwintered adult mosquitoes came to oviposit in paddy fields. Then hatched young mosquito larvae were killed timely by the application of the diphenylether herbicides. One time almost all of paddy fields in Japan were treated with such herbicides. Therefore, this is a possibility that these applications were so effective to decrease the patient number of Japanese encephalitis. This sickness is also very important in tropical countries. Also for the malaria control, this idea will be utilized.

Unfortunately nitrofen was over and chlornitrofen is not familiar. New diphenylether herbicides having a substituent next to nitro group have little activity to kill the mosquito larvae. However this information may be paid attention.

Dr. M. Soerjani (Indonesia) : A comment on Dr. Matsunaka's comment. There are some important species of plants that are used as biological indicators of air pollution, e.g. *Lichenes* and *Pinus* spp. to indicate pollution of SO₂. Are there more sensitive weed species to be used as bio-indicators for air pollution. In my opinion, it can be also very important to develop aquatic plants or terrestrial plants as bio-indicators for water or soil pollution.

Mr. Sener Buranapawang (Thailand) (via Dr. J.T. Swarbrick) : *Mimosa pigra* is a very important food source for honey bees in the Chiang Mai area in the wet season when few other major pollen sources are available. The Thai bee-keeper's industry current has about 30,000 hives producing honey for home consumption and for export. The other *Mimosa* species are probably also important honey sources, as is *Eupatorium odoratum*.

Dr. M. Blacklow (Australia) : The potential loss to beekeepers in northern Thailand if *Mimosa* spp. is controlled, is analogous to the concern by Australian beekeepers should *Echium* spp. be controlled by biological control agents.

There has been a long and, at times, emotional conflict between those who value *Echium* spp., the beekeepers and some pasturelists, and those who want biological control, producers of cereal crops and of livestock on improved pastures.

We now know it is necessary to identify and resolve any potential conflicts before costly research programs into biological control are undertaken. Therefore, we needed to established statutory law, through special legislation, so that biological control can proceed if it is seen to be in the national interest.

The Australian experience with *Echium* spp. is described in the recent issue of the Australian journal, Plant Protection Quarterly.

Dr. B.L. Mercado : It is very difficult to identify the final weeds. There is a lot of conflicts. We should have a workshop on this in the next conference.

CLOSING REMARKS

The topic, "Weeds and environment in the tropics", presents a very broad horizon to weed scientists in the Asian-Pacific region. The severity of weed population is determined largely by the biotic and abiotic environmental forces and the tropics provide an uninterrupted interaction between a weed and its environment. The papers presented created the impression that there are countless ways we can deal with weeds. We can utilize their potentials as useful plants; we can approach their control in more ways than one.

Utilization of weeds has been documented even in very early years. Hence, we have reports of particular weed species being utilized by certain groups of people for medicinal purposes. The use of water hyacinth for pulp and paper manufacture is well supported by the greeting card my family gets from Dr. Soerjani of Indonesia every special occasion. It represents ingenuity and resourcefulness put to good practice.

Allelopathy has been looked at many times in reference to plant interaction. Dr. Harada presented piscicidal activities from some aquatic weeds, an undesirable property that can be harnessed towards a desirable use. Now that the groundwork has been provided by the weed scientists, other biologists can pick it up for further application.

Weeds as alternate hosts of other pests has oftentimes been considered a minor undesirable effect of weeds. Dr. Bendixen, however, who has been working on the weed hosts of nematodes for some years already indicated that the "unseen" effect of weeds on nematode population particularly that of *Meloidogyne*, can contribute a considerable reduction in yield apart from direct competition for environmental resources.

Farming practices have influenced the quality and quantity of weed population. In many parts of Asia, shifting cultivation is a customary

practice in forested and hilly areas. Dr. Smitinand stressed the severity of perennial weed problems in this kind of agriculture where weeds are too difficult to control with the conventional methods. The practice itself presents a two-pronged problem that has been the subject of discussion during the 1983 conference in Manila. Shifting cultivation is an undesirable practice itself, bringing about socio-economic and agronomic problems.

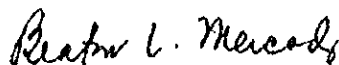

The agriculture of rice, the staple food of Asians, has undergone considerable changes since the introduction of the modern high yielding cultivars. Rice has become the guinea pig in technological changes in weed control. The shift from transplanted to broadcast-seeding in flooded rice promises an overall higher yield and less labor cost. As Dr. De Datta has put it, success is largely dependent on the efficacy and selectivity of the herbicide applied.

Interest on the increasing seriousness of introduced species like *Mimosa pigra* in Thailand generated information on its biology that revealed very interesting behavioral characteristics of the weed. Such information will help both in chemical and ecological approaches of control.

Aquatic weeds such as water hyacinth has been the subject of biological control studies for quite some time but the appropriate agent has been very elusive. Dr. Soerjani presented a novel approach to controlling aquatic weeds without depending largely on biological control and considering the total ecosystem.

We have looked at the soil often times as a "dumping ground" but the soil allows chemical and biological reactions that determine the behavior and fate of herbicides. Mother earth nurtures our food, clothing and shelter materials and Dr. Chen stressed the importance of soil-herbicide interaction particularly in rice agriculture.

The papers presented problems and possible solutions in some cases. In anyway we look at the weeds and the environment, there is always that mystery that needs to be unravelled for a better and economical control of weeds.

Beatriz L. MERCADO
Chairman/Editor

**PROGRAMME OF SYMPOSIUM:
WEEDS AND THE ENVIRONMENT IN THE TROPICS**
in the 10th Conference of Asian-Pacific Weed Science Society

Date : November 29, 1985

Location : The Royal Orchid Ballroom, Chiang Mai
Orchid Hotel, Chaing Mai, Thailand

Chairman : K. Noda (Thailand)

| 11:45-12:00 a.m. | Discussion |
| 12:00- 1:30 p.m. | Lunch |

Chairman : B.L. Mercado (The Philippines)

1:30- 2:00 p.m.	Allelopathy and fish - toxicity of weeds - J. Harada (Thailand)
2:00- 2:30 p.m.	Herbicides in the environment - Y.L. Chen (Taiwan, R.O.C.) and H. Nakayama (Japan)
2:30- 2:45 p.m.	Discussion
2:45- 3:30 p.m.	General discussion
3:30 p.m.	Closed

CONTRIBUTORS

Dr. Tanongchit WONGSIRI : *Deputy Director-General, Department of Agriculture, Ministry of Agriculture and Cooperatives (MOAC), Bangkok, Bangkok 10900, Thailand*

Dr. Kenji NODA : *Project Leader, National Weed Science Research Institute Project between Thailand and Japan, c/o Department of Agriculture, MOAC, Bangkok, Bangkok 10900, Thailand*

Dr. Hidejiro SHIBAYAMA : *Chief of Rice Cultivation Laboratory, Chugoku National Agricultural Experiment Station, MAFF, Fukuyama-shi, Hiroshima-Ken, Japan*

Dr. Paitoon KITTIPONG : *Chief, Weed Science Branch, Botany and Weed Science Division, Department of Agriculture, MOAC, Bangkok, Bangkok 10900, Thailand*

Dr. Mohamad SOERJANI : *Director, Centre for Studies of the Environment and Human Resources, The University of Indonesia, Jalan Salemba 4, Jakarta, Indonesia*

Dr. Surajit K. DE DATTA : *Principal Scientist and Head, Department of Agronomy, The International Rice Research Institute (IRRI), Los Baños (P.O.Box 933, Manila), Philippines*

Dr. John C. FLINN : *Head and Agricultural Economist, Department of Agricultural Economics, IRRI, Los Baños, Philippines*

Dr. Kil Ung KIM : *Associate Professor, Department of Agronomy, College of Agriculture, Kyungpook National University, Taegu 635, Korea*

Dr. Leo E. BENDIXEN : *Professor, Department of Agronomy, The Ohio State University, 2021 Coffey Rd., Columbus, Ohio 43210, U.S.A.*

Dr. Tem SMITINAND : *The Herbarium, Royal Forest Department, Bangkok, Bangkok 10900, Thailand*

Dr. Beatriz L. MERCADO : *Professor, Weed Science Division, Bio-Science Building, C-220, College, Laguna 37210, Philippines*

Dr. Jiro HARADA : *Expert, National Weed Science Research Institute Project between Thailand and Japan, c/o Department of Agriculture, MOAC, Bangkok, Bangkok 10900, Thailand*

Dr. Yuh-Lin CHEN : *Professor, Department of Agricultural Chemistry, National Taiwan University, Taipei, Taiwan, Republic of China*

Dr. Haruhiko NAKAYAMA : *Senior Staff, The Institute of Physical and Chemical Research, Wako-shi, Saitama-Ken, Japan*

INDEX OF PLANT SPECIES
(Excluded the Appendix of page 134 to 167)

A		<i>Artemisia roxburghiana</i>	80
<i>Abutilon hirtum</i>	96	<i>Arundinaria setosa</i>	80,82,83,89
<i>Abutilon indicum</i>	96	<i>Arundinella hispida</i>	81,83,89
<i>Acalypha indica</i>	93	<i>Asystasia salicifolia</i>	92
<i>Acalypha kerrii</i>	86,93	<i>Atylosia scaravioides</i>	95
<i>Acalypha mairci</i>	93	<i>Atylosia siamensis</i>	95
<i>Acalypha siamensis</i>	93	B	
<i>Achyranthes aspera</i>	92	<i>Bacopa monnieri</i>	192,200
<i>Achyranthes bidentata</i>	92	<i>Baliospermum montanum</i>	93
<i>Achyrosperrum wullichianum</i>	86,94	<i>Barleria cristata</i>	82,84,92
<i>Acorus calamus</i>	39	<i>Barleria siamensis</i>	92
<i>Acrocephalus indicus</i>	86,94	<i>Blumea aurita</i>	85,92
<i>Acroceras tonkinense</i>	89	<i>Blumea balsamifera</i>	85,92
<i>Aerva sanguinolenta</i>	92	<i>Blumea fistulosa</i>	82,85,92
<i>Aeschynomene americana</i>	189,199	<i>Blumea lacera</i>	82,85,92
<i>Aeschynomene aspera</i>	95	<i>Blumea oxydonta</i>	85,93
<i>Ageratina adenophylla</i>	82,85	<i>Blumeopsis falcata</i>	85,93
<i>Ageratina adenophora</i>	79	<i>Boehavia diffusa</i>	96
<i>Ageratina adenophorum</i>	80	<i>Boehavia repanda</i>	96
<i>Ageratum conyzoides</i>	80,81,82,85,92	<i>Boehmeria chiangmatensis</i>	87,97
<i>Alectra arvensis</i>	97	<i>Boehmeria chidemoides</i>	97
<i>Amaranthus blitum</i>	92	<i>Boehmeria diffusa</i>	97
<i>Amaranthus spinosus</i>	92	<i>Boehmeria macrophylla</i>	87,97
<i>Ammannia baccifera</i>	173,192, 194,195,200	<i>Boehmeria malabarica</i>	97
<i>Anaphalis adnata</i>	82,85,92	<i>Boehmeria pilosiuscula</i>	97
<i>Anaphalis margaritaceum</i>	82,85	<i>Boehmeria platyphylla</i>	87,97
<i>Andrographis glomeriflora</i>	92	<i>Boehmeria pseudotomentosa</i>	98
<i>Andrographis laxiflora</i>	84,92	<i>Boehmeria thailandica</i>	98
<i>Andrographis paniculata</i>	84,92	<i>Boehmeria zollingeriana</i>	98
<i>Ancilema scaberrimum</i>	88	<i>Borreria stricta</i>	97
<i>Anguina tritici</i>	180	<i>Bothriochloa pertusa</i>	83,89
<i>Anisochilus pallidus</i>	86,94	<i>Botrychium lanugiosum</i>	87
<i>Anisochilus siamensis</i>	86,94	<i>Brasenia spp.</i>	39
<i>Anisometes candicans</i>	86,94	<i>Breynia angustifolia</i>	93
<i>Apocopsis paleacea</i>	89	<i>Breynia retusa</i>	93
<i>Apocopsis siamensis</i>	89	<i>Breynia vitis-idaea</i>	93
<i>Archidendron glomeriflorum</i>	86	<i>Buchnera cruciata</i>	97
<i>Aristida balansae</i>	89	<i>Buddleja asiatica</i>	96
<i>Aristida cumingiana</i>	82,83	<i>Butomus umbellatus</i>	39
<i>Artemisia dubia</i>	79,80,82	C	
		<i>Callicarpa candicans</i>	190
		<i>Callicarpa maingayi</i>	190

<i>Calophyllum inophyllum</i>	190	<i>Cyanotis axillaris</i>	83,88
<i>Canna edulis</i>	44	<i>Cyanotis cristata</i>	88
<i>Capillipedium assimile</i>	80,82,83,89	<i>Cyathocline purpurea</i>	85
<i>Capillipedium parviflorum</i>	80,82,83,89	<i>Cyathula prostata</i>	92
<i>Carex baccans</i>	88	<i>Cymbopogon flexuosus</i>	80,82,83,89
<i>Carex continua</i>	89	<i>Cyperus compactus</i>	89
<i>Carex cruciata</i>	88	<i>Cyperus cuspidatus</i>	89
<i>Carex indica</i>	83,89	<i>Cyperus cyperinus</i>	83
<i>Carex stramonita</i>	89	<i>Cyperus cyperoides</i>	89
<i>Carex tricephala</i>	83,89	<i>Cyperus difformis</i>	52,55,56,57
<i>Cardioperis quinqueloba</i>	92	<i>Cyperus haspan</i>	52
<i>Cassia hirsuta</i>	95	<i>Cyperus iria</i>	57,62,89
<i>Cassia mimosoides</i>	86,95	<i>Cyperus leucocephalus</i>	83,89
<i>Cassia occidentalis</i>	95	<i>Cyperus rotundus</i>	79,89
<i>Cassia pumila</i>	86,95	<i>Cyperus sesquiflorus</i>	89
<i>Cassia tora</i>	95	<i>Cyperus tenuiculmis</i>	89
<i>Celosia argentea</i>	80		
<i>Cenotheca lappacea</i>	83,89	D	
<i>Centrostachys aquatica</i>	192	<i>Derris elliptica</i>	190
<i>Ceratophyllum demersum</i>	38	<i>Derris montana</i>	190
<i>Ceratophyllum spp.</i>	39	<i>Derris pubipetala</i>	190
<i>Chara zeylanica</i>	52	<i>Desmodium gangeticum</i>	95
<i>Chromolaena odorata</i>	79,80,81,82,85,93	<i>Desmodium gyroides</i>	95
<i>Cleome viscosa</i>	92	<i>Desmodium oblongum</i>	95
<i>Cnesmone javanica</i>	86,93	<i>Desmodium renifolium var. oblatum</i>	95
<i>Cnesmone laotica</i>	86,93	<i>Desmodium velutinum</i>	95
<i>Commelina benghalensis</i>	83,88	<i>Dianella ensifolia</i>	91
<i>Commelina diffusa</i>	83,88	<i>Dicranopteris curranii</i>	87
<i>Cosmos caudatus</i>	85,93	<i>Dicranopteris linearis</i>	80,81,83,87
<i>Cosmos sulfureus</i>	85,93	<i>Digitaria adscendens</i>	84,89
<i>Crassocephalum crepiditoides</i>	81,82,85,93	<i>Digitaria sanguinalis</i>	84,89
<i>Crotalaria acicularis</i>	95	<i>Digitaria violascens</i>	82,84,90
<i>Crotalaria alata</i>	95	<i>Dimeria ornithopoda</i>	82,84,90
<i>Crotalaria albida</i>	95	<i>Dryopteris cochleata</i>	83,87
<i>Crotalaria assamica</i>	86	<i>Dryopteris mollis</i>	89
<i>Crotalaria bracteata</i>	95	<i>Dunbaria longerracemosa</i>	95
<i>Crotalaria calycina</i>	95	<i>Dunbaria podocarpa</i>	95
<i>Crotalaria chinensis</i>	86	<i>Dyschoriste depressa</i>	84,92
<i>Crotalaria montana</i>	86,95	<i>Dysophylla auriculata</i>	94
<i>Crotalaria sessiliflora</i>	95	<i>Dysophylla stellata</i>	192,200
<i>Crotalaria spectabilis</i>	95	E	
<i>Crotalaria verrucosa</i>	86,95	<i>Echinochloa colona</i>	52
<i>Croton cascarilloides</i>	93	<i>Echinochloa colonum</i>	38
<i>Croton crassifolius</i>	93	<i>Echinochloa crus-galli ssp. hispidula</i>	52,55,56,58
<i>Croton kerrii</i>	93		
<i>Croton kongensis</i>	93	<i>Echinochloa glabrescens</i>	52,55,56,58

<i>Echinochloa stagnina</i>	38	<i>Fimbristylis rigidula</i>	89
<i>Echium</i> spp.	223	<i>Fimbristylis savannicola</i>	89
<i>Egeria densa</i>	38	<i>Fimbristylis thomsonii</i>	89
<i>Eichhornia crassipes</i>	1,2,37,38,39	<i>Flemingia kerrii</i>	95
<i>Eleocharis dulcis</i>	52	<i>Flemingia macrophylla</i>	95
<i>Elephantopus scaber</i>	93	<i>Flemingia strobilifera</i>	95
<i>Eleusine indica</i>	90	G.	
<i>Elsholtzia blanda</i>	94	<i>Germainia balansae</i>	90
<i>Elsholtzia kachinensis</i>	94	<i>Germainia khasiana</i>	90
<i>Elsholtzia winitiana</i>	94	<i>Germainia lanipes</i>	90
<i>Encelia forinosa</i>	175	<i>Geniosporum coloratum</i>	94
<i>Epimeredi indica</i>	86	<i>Geniosporum siamense</i>	86,94
<i>Epimeredi indicus</i>	94	<i>Givardinia heterophylla</i>	98
<i>Eragrostis burmanica</i>	84,90	<i>Gleichenia longissima</i>	87
<i>Eragrostis capensis</i>	82,84,90	<i>Glyceria fluitans</i>	39
<i>Eragrostis japonica</i>	90	<i>Gnaphalium affine</i>	85,93
<i>Eragrostis nutans</i>	84,90	<i>Gnaphalium hypoleucum</i>	85,93
<i>Eragrostis uniolooides</i>	82,84,90	<i>Golfussia anfractuosa</i>	84
<i>Eragrostis zeylanica</i>	84,90	<i>Golfussia rex</i>	84
<i>Eranthemum ciliata</i>	92	II	
<i>Eremochloa bimaculata</i>	90	<i>Hedyotis capitellata</i>	97
<i>Eremochloa eriopoda</i>	90	<i>Hedyotis coronaria</i>	97
<i>Erigeron annuus</i>	175	<i>Hedyotis fulva</i>	97
<i>Eriostrobilus bombycinus</i>	84	<i>Hedyotis rosmarifolia</i>	97
<i>Eucalyptus grandis</i>	174	<i>Helicteres angustifolia</i>	97
<i>Eulalia bicornuta</i>	90	<i>Helicteres hirsuta</i>	97
<i>Eulalia birmanica</i>	90	<i>Helicteres isora</i>	97
<i>Eulalia phaeothrix</i>	90	<i>Helicteres obtusa</i>	97
<i>Eulalia siamensis</i>	82,90	<i>Helicteres viscida</i>	97
<i>Eulalia smitinandiana</i>	90	<i>Heliotropium indicum</i>	92,189,199
<i>Eupatorium cannabinum</i>	85	<i>Helminthostachys zeylanica</i>	87
<i>Eupatorium odoratum</i>	189,199,223	<i>Heracleum siamicum</i>	87
<i>Euphorbia capillaris</i>	86,94	<i>Heteropogon contortus</i>	90
<i>Euphorbia coudercii</i>	94	<i>Heteropogon triticeus</i>	80,90
<i>Euphorbia hirta</i>	94	<i>Hibiscus surattensis</i>	96
<i>Euphorbia hypericifolia</i>	86,94	<i>Histiopteris incisa</i>	87
<i>Euphorbia prolifera</i>	94	<i>Hura crepitans</i>	190
<i>Evolvulus alsinoides</i>	93	<i>Hydrilla verticillata</i>	38
F		<i>Hyparrhenia bracteata</i>	84,90
<i>Fimbristylis dichotoma</i>	83,89	<i>Hyparrhenia rufa</i>	81,82,84,90
<i>Fimbristylis eragrostis</i>	89	<i>Hypolepis punctata</i>	87
<i>Fimbristylis fusca</i>	89	<i>Hypptis suaveolens</i>	86,94,189,199
<i>Fimbristylis hookeriana</i>	89	I	
<i>Fimbristylis junciflorus</i>	89	<i>Ichthyothere terminalis</i>	190
<i>Fimbristylis miliacea</i>	52	<i>Imperata cylindrica</i>	79,80,81,82,84,220
<i>Fimbristylis monostachyos</i>	83,89	<i>Indigofera squalida</i>	86

<i>Indigofera sutepensis</i>	86	M	
<i>Inula cappa</i>	85,93	<i>Mallotus barbatus</i>	94
<i>Inula crassifolia</i>	85	<i>Mallotus garrettii</i>	94
<i>Inula eupatorioides</i>	85,93	<i>Mallotus khasianus</i>	94
<i>Inula indica</i>	93	<i>Mallotus repandus</i>	94
<i>Inula nervosa</i>	85	<i>Maoutia puya</i>	98
<i>Ipomoea aquatica</i>	33,39,192	<i>Marsilia crenata</i>	52
<i>Isachne globosa</i>	52	<i>Massia triseti</i>	90
<i>Ischaemum barbatum</i>	84,90	<i>Melastoma malabathricum</i>	96
<i>Ischaemum rugosum</i>	84,90	<i>Melastoma normale</i>	96
J		<i>Melochia corchorifolia</i>	97
<i>Juglans mandshurica</i>	190	<i>Merremia umbellata</i>	93
<i>Juglans nigra</i>	175	<i>Merremia vitifolia</i>	93
<i>Juncus effusus</i>	91	<i>Microleptia speluncae</i>	87
<i>Juncus prismatocarpus</i>	91	<i>Microstegium vagans</i>	84,90
<i>Jussiaea repens</i>	52	<i>Mimosa invisa</i>	86
<i>Justica hayatai</i> var. <i>decumbens</i>	190	<i>Mimosa pigra</i>	1,5,6,7,8,9,10,11,12,13, 14,15,16,17,18,19,20,21,22,23,24,25, 26,29,31,38,77,80,86,189,192,200,223,226
K		<i>Mimosa</i> spp.	223
<i>Knoxia corymbosa</i>	97	<i>Mimulus orbicularis</i>	52,
L		<i>Monochoria vaginalis</i>	38,52,55,56,58
<i>Laggera alata</i>	85,93	<i>Mucuna pruriens</i>	95
<i>Lantana camara</i>	98	<i>Murdannia gigantea</i>	83,88
<i>Lantana trifolia</i>	98	<i>Murdannia nudiflora</i>	88
<i>Leersia hexandra</i>	52	<i>Myriophyllum demersum</i>	45
<i>Lepidagathis chiangmaiensis</i>	84	<i>Myriophyllum</i> spp.	39
<i>Lepidagathis fasciculata</i>	84	N	
<i>Lepidagathis incurva</i>	84,92	<i>Nelumbo nucifera</i>	38,39
<i>Lepidagathis thyrsiflora</i>	84,92	<i>Neptunia natans</i>	192
<i>Leptaspis urceolata</i>	90	<i>Neyraudia arundinacea</i>	90
<i>Leptocarpus disjunctus</i>	92	<i>Neyraudia reynaudiana</i>	82,90
<i>Leptochloa chinensis</i>	52	<i>Nosema cochinchinensis</i>	95
<i>Lepturus repens</i>	90	O	
<i>Leucas aspera</i>	94	<i>Oenanthe javanica</i>	173,180,183,184, 186,187,199
<i>Leucas ciliata</i>	86,94	<i>Ophioglossum petiolatum</i>	87
<i>Leucas lanata</i>	94	<i>Oplismenus compositus</i>	84,90
<i>Leucas mollissima</i>	86,94	<i>Oryza grandata</i>	90
<i>Leucas zeylanica</i>	95	<i>Oryza perennis</i>	76
<i>Limnocharis flava</i>	39	<i>Oryza rufipogon</i>	76
<i>Lophatherum gracile</i>	90	<i>Oryza sativa</i>	184
<i>Lygodium flexuosum</i>	88	<i>Osbeckia chinensis</i>	96
<i>Lygodium giganteum</i>	88	<i>Osbeckia pulchra</i>	96
<i>Lygodium japonicum</i>	88	<i>Osbeckia stellata</i>	96
<i>Lygodium microphyllum</i>	88		
<i>Lygodium polystachyum</i>	88		
<i>Lygodium salicifolium</i>	88		

<i>Ottocloa nodosa</i>	90	<i>Polygala crotolaroides</i>	96
P		<i>Polygala glomerata</i>	96
<i>Paederia foetida</i>	97	<i>Polygala longifolia</i>	86,96
<i>Paederia linearis</i>	97	<i>Polygala tricholopha</i>	96
<i>Paederia tomentosa</i>	97	<i>Polygonum arenastrum</i>	179,184
<i>Panicum auritum</i>	90	<i>Polygonum aviculare</i>	179,184
<i>Panicum incomitum</i>	90	<i>Polygonum caespitosum</i> ssp.	
<i>Panicum notatum</i>	84,90	<i>yokusaianum</i>	179,184
<i>Panicum repens</i>	38	<i>Polygonum chinense</i>	86,96
<i>Parasympagis gartelii</i>	84	<i>Polygonum conspicuum</i>	178,179,184
<i>Parthenium argentatum</i>	175	<i>Polygonum cuspidatum</i>	179,184
<i>Paspalidum flavidum</i>	90	<i>Polygonum filiforme</i>	179,184
<i>Paspalum conjugatum</i>	90	<i>Polygonum hydropiper</i>	96,178,179,180, 181,182,183,184,190,199
<i>Paspalum distichum</i>	63,68	<i>Polygonum japonicum</i>	178,179,184
<i>Paspalum longifolium</i>	90	<i>Polygonum lapathifolium</i>	179,184
<i>Paspalum scrobiculatum</i>	91	<i>Polygonum lapathifolium</i>	
<i>Passiflora foetida</i>	96	ssp. <i>nodosum</i>	178,179,184
<i>Pavonia rigida</i>	96	<i>Polygonum longisetum</i>	178,179,184
<i>Pennisetum pedicellatum</i>	91	<i>Polygonum nepalense</i>	179,184
<i>Pennisetum polystachyon</i>	91	<i>Polygonum nipponense</i>	178,179,184
<i>Pennisetum purpureum</i>	91	<i>Polygonum orientale</i>	179,184
<i>Pennisetum</i> spp.	1	<i>Polygonum paleaceum</i>	86
<i>Pericampylus glaucus</i>	96	<i>Polygonum perfoliatum</i>	179,184
<i>Pericampylus incanus</i>	96	<i>Polygonum pubescens</i>	179,184
<i>Perilepta auriculata</i>	92	<i>Polygonum sachalinense</i>	179,184
<i>Perilepta siamensis</i>	92	<i>Polygonum sagittatum</i>	
<i>Perilla frutescens</i> var. <i>japonica</i>	175	var. <i>sieboldii</i>	178,179,184
<i>Perilla frutescens</i> var. <i>crispa</i>	175	<i>Polygonum</i> spp.	39
<i>Peristrophe lauceolaria</i>	92	<i>Polygonum strigosum</i>	96
<i>Perotis indica</i>	91	<i>Polygonum thumbergii</i>	178,179,184
<i>Phragmites australis</i>	91	<i>Polygonum tomentosum</i>	189,192,200
<i>Phragmites communis</i>	39	<i>Polytoca digitata</i>	91
<i>Phyllanthus acutissimus</i>	94	<i>Polytoca wallichiana</i>	91
<i>Phyllanthus amarus</i>	86,94	<i>Potamogeton malayanus</i>	192
<i>Phyllanthus clarkei</i>	94	<i>Pouzolzia pentandra</i>	98
<i>Phyllanthus elegans</i>	94	<i>Pseuderanthemum andersonii</i>	85
<i>Phyllanthus sootepensis</i>	94	<i>Pseudopogonatherum contortum</i>	91
<i>Phyllanthus virgatus</i>	94	<i>Pteridium aquilinum</i>	80,81,83
<i>Phyllodium pulchellum</i>	95	<i>Pteridrys syntactica</i>	87
<i>Physalis minima</i>	81,87,97	<i>Pteris biauarta</i>	87
<i>Piloselloides hirsuta</i>	85	<i>Pteris heteromorpha</i>	87
<i>Pistia stratiotes</i>	38,192	<i>Pteris vittata</i>	87
<i>Pityrogramma calomelanos</i>	87	<i>Pueraria candollei</i>	95
<i>Podocarpus</i> spp.	174	<i>Pueraria thomsonii</i>	95
<i>Pogonatherum crinitum</i>	91		

R			
<i>Ranunculus quelpaertensis</i> var. <i>glabra</i>	184	<i>Schizachyrium brevifolium</i>	91
<i>Reinwardtia trigyna</i>	96	<i>Scirpus grossus</i>	52
<i>Rhynchelytrum repens</i>	91	<i>Scirpus juncooides</i>	52
<i>Rinorea virgata</i>	98	<i>Scirpus maritimus</i>	55,56,57,58,62,63,66,68
<i>Rorippa nasturtium-aquaticum</i>	39	<i>Scirpus</i> spp.	39
<i>Rostrellularia chiangmaiensis</i>	82,85	<i>Scleria ciliaris</i>	89
<i>Rostrellularia cradengensis</i>	82,85	<i>Scleria kerrii</i>	89
<i>Rostrellularia neglecta</i>	82,85	<i>Scleria levis</i>	83,89
<i>Rostrellularia</i> spp.	92	<i>Scleria lithosperma</i>	89
<i>Rotboellia exaltata</i>	91	<i>Scleria pergracilis</i>	83,89
<i>Rubus alceifolius</i>	96	<i>Scleria terrestris</i>	89
<i>Rubus ellipticus</i>	96	<i>Scleria tonkinensis</i>	89
<i>Rubus rufus</i>	97	<i>Sclerostachya fusca</i>	91
<i>Rubus rugosus</i>	97	<i>Scoparia dulcis</i>	97
<i>Rumex acetosa</i>	179,184	<i>Securinega virosa</i>	94
<i>Rumex crispus</i>	96	<i>Sehima nervosum</i>	91
<i>Rumex crispus</i> ssp. <i>japonicus</i>	179,184	<i>Selaginella bififormis</i>	88
<i>Rumex obtusifolius</i>	178,179,184	<i>Selaginella chrysorrhizos</i>	83
<i>Rumex vesicarius</i>	96	<i>Selaginella delicatula</i>	88
<i>Rungia maculata</i>	82	<i>Selaginella helferi</i>	83,88
<i>Rungia parviflora</i>	85	<i>Selaginella intermedia</i>	88
<i>Rungia</i> spp.	92	<i>Selaginella involvens</i>	88
<i>Rytidix gratularis</i>	82,84	<i>Selaginella kurzii</i>	88
S		<i>Selaginella minutifolia</i>	88
<i>Saccharum arundinaceum</i>	79,80,81,82,84,91	<i>Selaginella monospora</i>	83
<i>Saccharum procerum</i>	91	<i>Selaginella ostensfeldtii</i>	83,88
<i>Saccharum spontaneum</i>	91	<i>Selaginella pubescens</i>	88
<i>Sacciolepis indica</i>	91	<i>Selaginella repanda</i>	83
<i>Sacciolepis myosuroides</i>	91	<i>Selaginella roxburghii</i>	88
<i>Sagittaria sagittifolia</i>	39	<i>Selaginella siamensis</i>	83,88
<i>Sagittaria</i> spp.	39	<i>Selaginella tenuifolia</i>	88
<i>Salomonia cantoniensis</i>	86,96	<i>Senecio nagensium</i>	85
<i>Salomonia ciliata</i>	86,96	<i>Sericoaelyx quadrifarius</i>	92
<i>Salvia leucophylla</i>	174	<i>Sesbania javanica</i>	192
<i>Salvinia molesta</i>	37,38	<i>Setaria glauca</i>	91
<i>Sauropus androgynus</i>	94	<i>Setaria pallide-fusca</i>	91
<i>Sauropus bicolor</i>	94	<i>Setaria palmifolia</i>	91
<i>Sauropus hirsutus</i>	94	<i>Setaria plicata</i>	84,91
<i>Sauropus orbicularis</i>	94	<i>Setaria verticillata</i>	91
<i>Sauropus quadrangularis</i>	94	<i>Sida acuta</i>	96
<i>Sauropus similis</i>	94	<i>Sida rhombifolia</i>	96
<i>Saussurea deltoidea</i>	85	<i>Siegesbeckia orientalis</i>	93
<i>Saussurea peguensis</i>	85	<i>Solanum erianthum</i>	97
<i>Saussurea venosa</i>	85	<i>Solanum nigrum</i>	97
		<i>Solanum torvum</i>	97
		<i>Solidago altissima</i>	175,184

<i>Sorghum halepense</i>	91	Z	
<i>Sorghum nitidum</i>	84,91	<i>Zingiber</i> spp.	44
<i>Sphenochlea zeylanica</i>	52,192,200	<i>Zizania latifolia</i>	39
<i>Spilanthes acmella</i>	93		
<i>Spilanthes iabadicensis</i>	85		
<i>Spodiopogon lacei</i>	84,91		
<i>Sporobolus diander</i>	91		
<i>Sporobolus kerrii</i>	84,91		
<i>Stachytarpheta indica</i>	98		
<i>Striga lutea</i>	97,175		
<i>Strobilanthes</i> spp.	92		
T			
<i>Tadchagi triquetrum</i>	95		
<i>Teucrium quadrifarium</i>	86,95		
<i>Themeda arundinacea</i>	80,82,84,91		
<i>Themeda quadrivalvis</i>	91		
<i>Themeda triandra</i>	80,84,91		
<i>Thelypteris cylindrothrix</i>	88		
<i>Thelypteris dentata</i>	88		
<i>Thelypteris hirsutipes</i>	88		
<i>Thelypteris interrupta</i>	88		
<i>Thelypteris truncata</i>	88		
<i>Thysanolaena maxima</i>	80,81,82,84,91		
<i>Tithonia diversifolia</i>	79,80,82,85		
<i>Tricholepis karenium</i>	85		
<i>Tridax procumbens</i>	93		
<i>Trifolium pratense</i>	219		
<i>Trigonostemon reidioides</i>	94		
<i>Triumfetta annua</i>	97		
<i>Triumfetta pilosa</i>	97		
<i>Triumfetta pseudo-cana</i>	97		
<i>Triumfetta rhomboidea</i>	97		
<i>Typha angustifolia</i>	38		
<i>Typha</i> spp.	39		
U			
<i>Uraria lagopodioides</i>	95		
<i>Uraria macrosachya</i>	95

<i>Verbena officinalis</i>	87,98		
<i>Vernonia cinerea</i>	85,93		
<i>Vernonia elliptica</i>	93		
<i>Vernonia silhetensis</i>	93		
<i>Vernonia spirei</i>	93		
<i>Vernonia squarrosa</i>	85		
<i>Vetiveria zizanioides</i>	91		
<i>Viburnum avabuki</i>	190		

INDEX OF CHEMICALS

A	
3-acetyl-6-methoxybenzaldehyde	175,176
ACN	204,205
alachlor	206,207
allyl MCP	205
apiole	177,186
B	
bensulfuron methyl	56,58,63,64,65,66,67,68
bensulide	202,204
benzone	55,61,62,63,203,204,209,213
benthiocarb	202,204,212,213,214
bifenox	202,213,214
biochanin	177
bromobutide	203,212
butachlor	53,54,55,57,59,60,202,206,207,209,212,213
C	
callicarpone	190,191,194
camphor	174,176
chlomethoxynil	202,212,213,214
chlornitrofen	57,202,213,220,223
chlorthiamid	205
cincole	174,176
CNP	202
eredazine	202,209,213
D	
2,4-D	6,45,54,55,56,57,58,59,60,62,63,64,65,66,67,68,204,207,212,213
2,4-D amine salt	205
2,4-D butyl ester	54
2,4-D ethyl	213
2,4-D ethyl ester	205
2,4-D sodium salt	205,207
daidzein glucoside	177
DBN	202
DCBN	205
DCPA	202
cis-dehydromatricaria ester	175,176,194
dicamba	5,22,24,25,26,31
diehtobenil	202
dimethametryn	53,202
dymron	203
E	
EPTC	56,57

F	
fluzifop butyl	54,55,61,62
flucthiuron	203
formononetin	177
fosamine	22,23,25
G	
genestein	177
glyphosate	5,22,23,24,25,26,31
gramin	175,176
H	
hordenin	175
hura toxin	190,191,194
<i>p</i> -hydroxycinnamic acid	175,177
I	
ichthyothereol	190,191
inophyllolide	190,191,194
inunakilactone	174,176
J	
juglone	175,176,191,220
justicidin	190,191,194
L	
lactinophyllum ester	175,177
M	
maingayic acid	191
matricaria ester	175
MCC	205
MCP ethyl ester	205
MCPA	59,202,204,213
MCPA ethyl	213
MCPB	204
MCPB ethyl ester	205,212
methoxyphenone	202,204,209,212
MO	59
mofinate	54,56,57,202,204,209,212,213
myristicin	186
N	
nagilactone	174,176
α -naphthoquinone	191,196
naproanilide	57,59,212,213
nitrofen	60,213,222
O	
ononin	177
oxadiazon	54,202,213
oxyfluorfen	56,58,203
P	
2,4-PA	205

paraquat	6
PCP	212,213
PCP sodium salt	205
pendimethalin	57,60,203
perilla aldehyde	175,177
perilla ketone	175,177
phenopylate	202
phenothiol	204,205,213
picloram	5,22,24,26,31
piperophos	53,54,60,202
podolactone	174,176,177
polyacetylene	174,176
polygodial	177,180,190
ponalactone	174,176
PPG 844 (lactofen)	57
prometryn	205,213
propanil	55,56,61,63,64,65,66,67,68,202,213
pyrazolate	54,205
pyridate	57,59
Q	
quinchlora	57,59
R	
R-24216	56,57
rofenone	190,191
S	
SC-0254	57,59
silvex	45
simazine	207,209
simetryn	204,205,212,213
strigol	177,178,221
swep	205,213
T	
<i>t</i> -cinnamic acid	175,176
thiobencarb	53,54,56,57,58,59,60,202
thiochloromethyl	203
2,4,5-TP	6
2-trans, 8-cis-matricaria ester	175,177
trichlopyr	5,22,24,25,26,31,203
trifolirhizin	177
trifluralin	54,202,213
V	
vibsanine	190,191,194
