APPENDIX 4, SURVEY ON TRAFFIC VOLUME

CONTENTS

	Page
1. Outline	1
2. Traffic volume shown by direction at intersections 12 hrs., from Jan. 13 to 17	11
3. Traffic inflow and outflow at intersections 12 hrs., Jan. 14	27
4. Peak traffic volume shown by direction at intersections, Jan. 14	30
5. Total and peak traffic volume shown by direction at intersections, Jan. 14	34
6. Traffic inflow and outflow shown by type of vehicle, Jan. 14	38

1. Outline

(a) Existing Traffic Conditions

The results of traffic sampling carried out at major junctions for 5 days from January 13, 1978 (Friday) to 17 (Tuesday) are as shown in Fig. 2.2.6. As a result of this traffic analysis, the traffic characteristics of Pattaya are itemized below.

(1) Weekly variation

The peak traffic volume was identified on Saturday and Sunday. This is probably because the traffic volume is due to the tourism traffic pattern of Pattaya.

(2) Traffic volume by types of vehicles

In the case of the Sukhavit Highway, passenger cars and trucks account for a large percentage of the traffic volume, and in the case of the main roads in the study area, the baht bus traffic is overwhelmingly large in volume (the baht bus is a local bus which has been remodelled out of a small truck). The baht bus is an important form of short distance transportation.

(3) Ratio of daytime to nighttime traffic volume

The differential ratio of daytime to nighttime traffic volume is as high as 1.62 on average; especially, the ratio for baht buses is high.

(b) Forecasting Method of Traffic Volume

The forecasting of the future origins and destinations of the traffic in terms of volume and the distribution of the traffic volume is made on a flow chart in Fig. 2.3.3.

(c) Estimation of the Origins and Destinations of the Traffic in Terms of Volume

(1) Zoning

The study area is sub-divided into 21 zones, as shown in Fig. 2.3.4 taking into consideration the present landuse, road network and the master plan.

(2) Setting the factors of the origin and destination unit

The origin and destination unit can be found by dividing the existing origin and destination traffic volume by zones by the existing value of the explanatory variable.

(a) Existing Traffic Conditions

The results of traffic sampling carried out at major junctions for 5 days from January 13, 1978 (Friday) to 17 (Tuesday) are as shown in Fig. 2.2.6. As a result of this traffic analysis, the traffic characteristics of Pattaya are identified below.

(1) Weekly variation

The peak traffic volume was identified on Saturday and Sunday. This is probably because the traffic volume is due to the tourism traffic pattern of Pattaya.

(2) Traffic volume by types of vehicles

In the case of the Sukhavit Highway, passenger cars and trucks account for a large percentage of the traffic volume, and in the case of the main roads in the study area, the baht bus traffic is overwhelmingly large in volume (the baht bus is a local bus which has been remodelled out of a small truck). The baht bus is an important form of short distance transportation.

(3) Ratio of daytime to nighttime traffic volume

The differential ratio of daytime to nighttime traffic volume is as high as 1.62 on average; especially, the ratio for baht buses is high.

(b) Forecasting Method of Traffic Volume

The forecasting of the future origins and destinations of the traffic in terms of volume and the distribution of the traffic volume is made on a flow chart in Fig. 2.3.3.

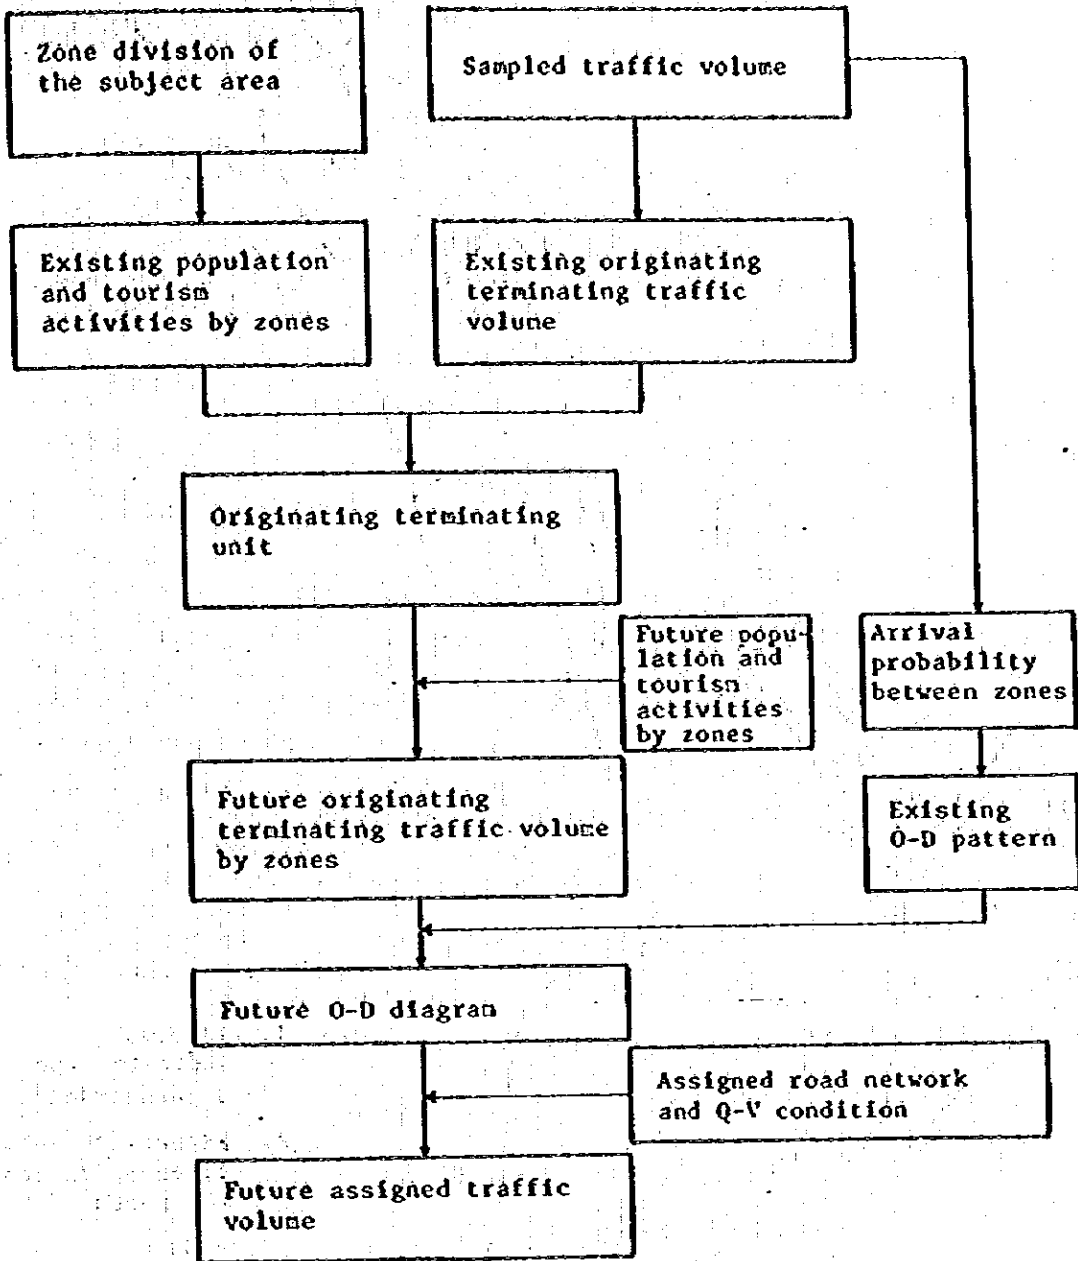

(c) Estimation of the Origins and Destinations of the Traffic in Terms of Volume

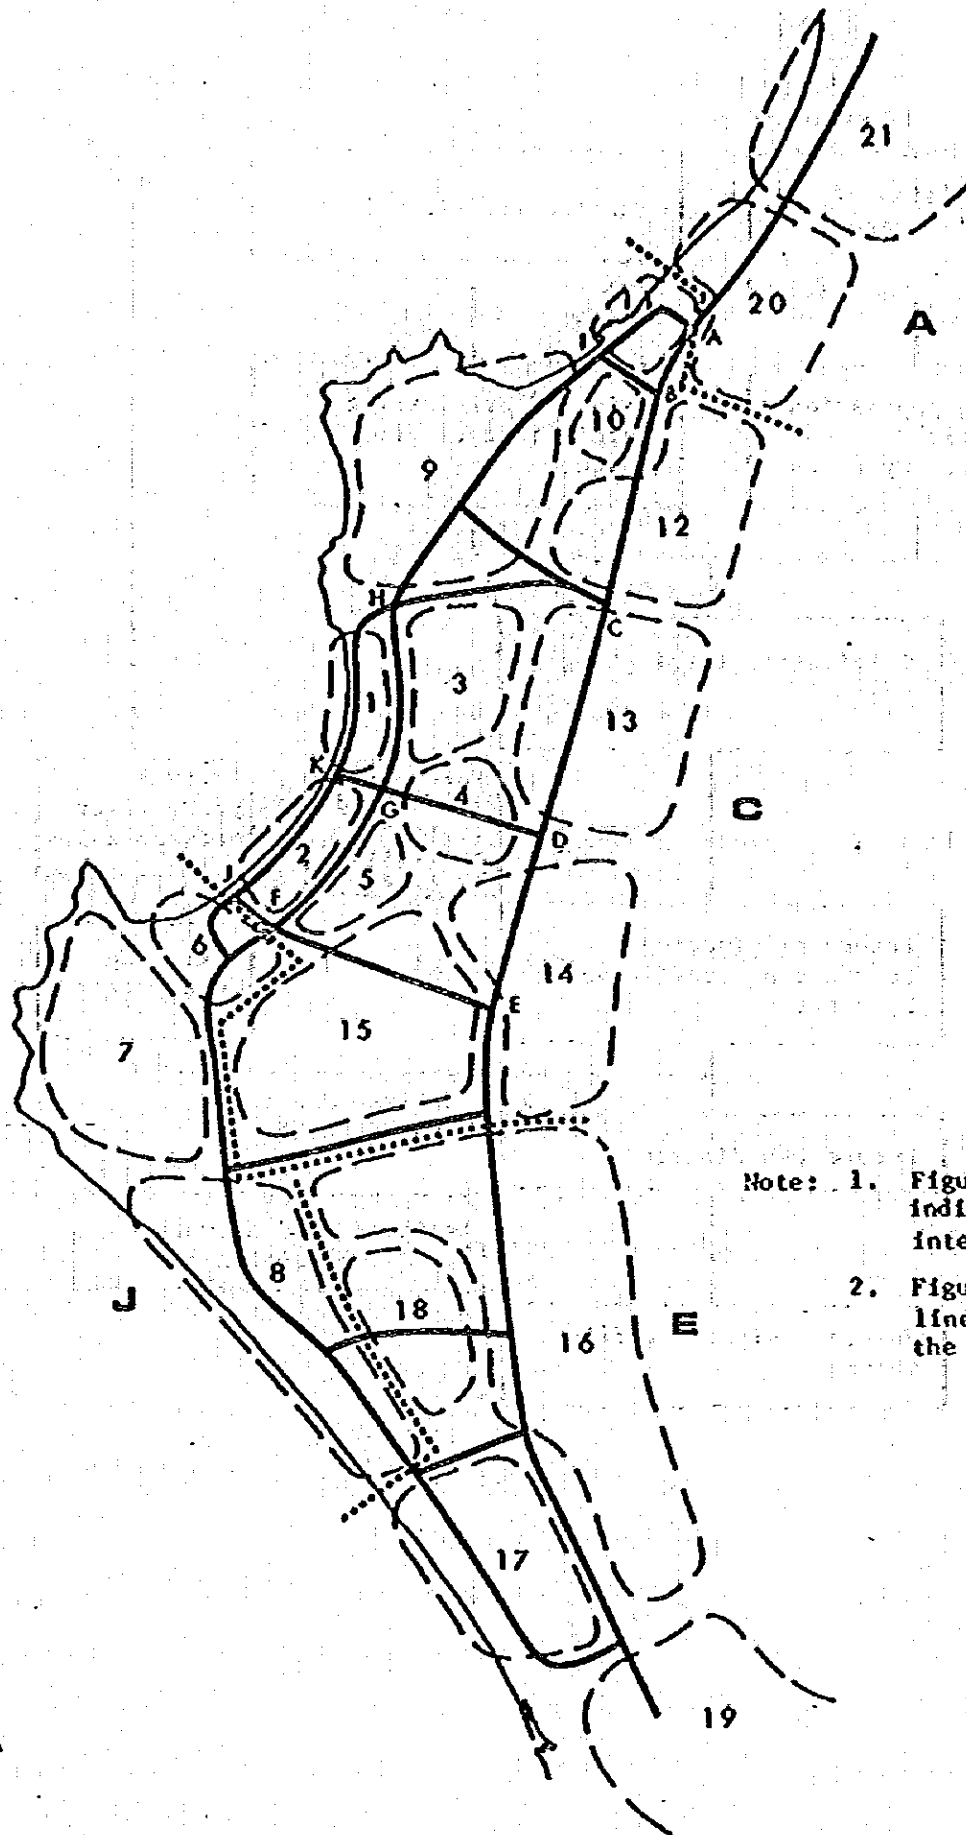

(1) Zoning

The study area is sub-divided into 21 zones, as shown in Fig. 2.3.4 taking into consideration the present landuse, road network and the master plan.

(2) Setting the factors of the origin and destination unit

The origin and destination unit can be found by dividing the existing origin and destination traffic volume by zones by the existing value of the explanatory variable.

Note: 1. Figures indicates the intersections.
 2. Figures in dotted lines or indicate the zones.

A
A

The explanatory variable used consists of the following combination of population, number of employees, and number of tourists by type of vehicle.

Origin and destination unit \times Existing Origin-destination traffic volume by zones
Existing value of explanatory variable by zones

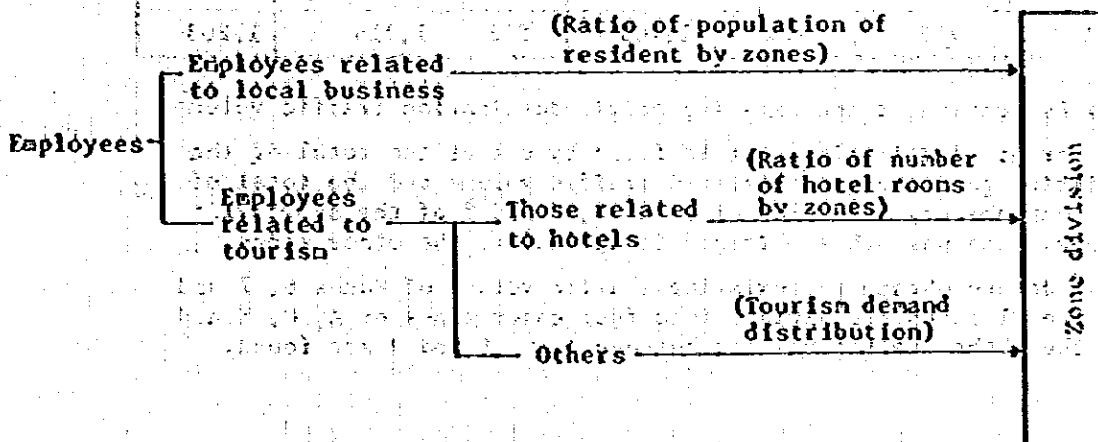

Type of vehicle	Explanatory variable
Baht-buses	Population of residents + number of workers + number of staying visitors + tourism demand
Passenger cars	
Trucks	Population of residents + number of workers

a. Resident-population by zone

The population of residents by zones was calculated on the basis of the total population forecasted in the master plan by dividing the population in proportion of the landuse plan.

b. Number of workers by zones

The number of forecasted workers in the master plan was applied by dividing the workers in the proportions of the population in each zone. The workers related to tourism are divided into those related to hotels and others according to the master plan. The former are divided in proportion to the ratio of the number of hotel rooms by zones, and the latter are divided in proportion to the ratio of tourism demand distribution of (iv) by zones.

c. Night staying tourists

The number of night staying tourists by zones used in the number of visitors staying at hotels and bungalows, and divided in proportion to the ratio of the number of hotel rooms by zones.

d. Tourism demand

In the case of the future value of the tourism activities demand by zones, the number of tourists forecasted tourism facilities in the master plan is used, and the numbers are totalled by zones. The existing value is counted back by use of the future value and the estimated grow rate. All of the above explanatory variables are shown in Table 2.3.1.

Table 2.3.1 Explanatory Variables by Zones

21	(Outside the area)					
Total	743	595	1,109	842	1,719	1,203

(3) Estimation of the existing origin-destination traffic volume

The origin-destination unit is found by use of the total of the existing generated-concentrated traffic volume and the total of the explanatory variables of Zones 6, 7 and 8 of the above 21 zones. The unit thus obtained is applied to the other zones.

In order to obtain the existing traffic volume of Zones 6, 7 and 8, the 21 zones are divided into four major zones or A, C, E and J, then, the traffic volumes between A, C, E and J are found.

Major Zone	21 Zones
A	20 and 21
C	1 to 5, and 9 to 15
E	16 to 19
J	6, 7 and 8

The work process is explained in order as follows:

a. Of the traffic sampling results, the incoming and outgoing traffic volumes at the intersections by type of vehicle is converted into a 24-hour traffic volume using the ratio of daytime to nighttime.

The incoming and outgoing traffic volumes at the intersections (A, E, F and J) located at the respective contacts of Zone C and Zones A, E and J of the sampling intersections are a total of the origin-destination traffic volumes of the respective zones of A, E and J.

b. The ratio of traffic volume by directions at the respective intersections is calculated by the sampling results of traffic volume.

c. Set all the routes thinkable as the traffic between Zones A, E and J passes through them by referring to the distances.

d. Calculate the ratio of arrival probabilities between zones for each route.

$$P_{ln} = \sum_{k=1}^l (P_{k1} \cdot P_{k2} \cdot \dots \cdot P_{kn})$$

P_{ln} : Arrival probability between zones $l \rightarrow n$ (%)

P_{kl} : Ratio of traffic volume by directions at the intersections included in k route between $l \rightarrow n$ zone (%)

$l = A \text{ or } E \text{ or } J$ $n = A \text{ or } E \text{ or } J$ $l \neq n$

e. The traffic volumes between Zones A, C, E and J can be found by use of the incoming and outgoing traffic volumes at intersection A, E, F and J and the arrival probabilities there.

1. Between Zones A, E and J:

$$Q_{ln} = q_{ln} \frac{P_{ln}}{100} + q_{nl} - \frac{P_{nl}}{100}$$

Q_{ln} : Traffic volume between l and n zones

q_{ln} : The sum of the exit traffic volumes in the direction n at l intersection (However, as for Zone J, assure that the sum of the traffic volumes at J and F intersections is that of l intersection.)

$l = A \text{ or } E \text{ or } J$ $n = A \text{ or } E \text{ or } J$ $l \neq n$

2. Between Zones A, E and J, and Zone C:

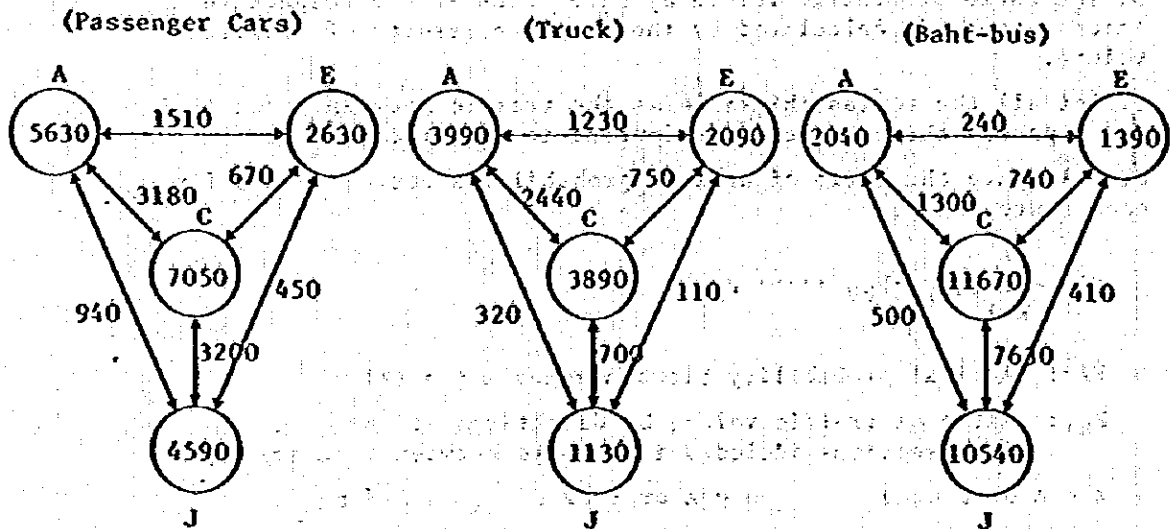

$$Q_{tc} = q_t - \sum Q_{tm}$$

Q_{tc} : Traffic volume between t and C zones

q_t : The sum of the incoming and outgoing traffic volumes at t intersection. (However, as for Zone J, assume that the sum of the traffic volumes at J and F intersections is that of t intersection.)

$$t = A \text{ or } E \text{ or } J \quad m = A \text{ or } E \text{ or } J \quad t \neq m$$

The traffic volumes by types of vehicles between major zones obtained in the above process are shown below.

f. The traffic volumes obtained as above are those between major zones, excluding the intra-zone traffic in major zones. Hence, paying attention to Zone J, divide the traffic volume between J and C in proportion to the ratio of the explanatory variable of the origin-destination unit, and assume that the result thus obtained is the intra-zone traffic volume in Zone J. The volume obtained by adding this intra-zone traffic volume to J-Zone origin-destination traffic volume between major zones obtained according to (i) is a true J-Zone origin-destination unit.

(4) Origin-destination unit

Find the origin-destination unit by dividing the existing origin-destination traffic volume of J Zone (Zones 6, 7 and 8) obtained as above by the explanatory variable.

a. Passenger cars and buses

J-Zone origin-destination traffic volume (trip end)

$$4,590 + 2 \times 3,200 \times \frac{101}{393} \doteq 6,230 \text{ trips}$$

Origin-destination origin unit (trip end)

$$6,230 \text{ (trips)} / 188 \text{ (100 persons)} = 33.14 \text{ (trips/100 per.)}$$

b. Trucks

J-Zone origin-destination traffic volume (trip end)

$$1,130 + 2 \times 700 \times \frac{101}{393} = 1,490 \text{ trips}$$

Origin-destination origin unit (trip end)

$$1,490 / 101 = 14.75 \text{ (trips/100 per.)}$$

c. Baht buses (No intra-zone traffic is taken into consideration in view of the baht-bus running characteristics.)

J-Zone origin-destination traffic volume (trip end)

$$10,540 \text{ trips}$$

Origin-destination origin unit (trip end)

$$10,540 / 188 = 56.06$$

(5) Origin-destination traffic volume

The traffic volume by zones is calculated by multiplying the origin-destination unit by the explanatory variable by zones; it is shown in Table 2.3.2. In the case of Zones 19 and 21 without the explanatory variable, the origin-destination traffic volume is calculated by deducting the known small-zone origin-destination traffic volume from the total origin-destination traffic volume of Zone E and Zone A. In the case of the buses and baht-buses, their running characteristics are taken into account so that in some zones, the origin-destination traffic volumes are a little corrected.

(d) Estimation of Distributed Volume

(1) Setting of OD pattern

The OD pattern is set by use of the incoming probability between zones as previously mentioned. The incoming probability between zones previously described is calculated between the major zones of A, E and J, but here the same calculation is made between minor zones; the results of which are made into the OD pattern as given in Table 2.3.3 (1) to Table 2.3.3 (3).

(2) Future distributed traffic volume

The future OD diagram was prepared by use of the OD pattern referred to in the preceding paragraph on the basis of the future origin-destination traffic volume and by making the convergence calculation according to the Fratar method. Table 2.3.4 (1) to Table 2.3.4 (9) show the present and the future OD diagrams by types of vehicles.
