PREFACE

In response to a request of the Government of the Federative Republic of Brazil, the Government of Japan decided to dispatch experts for the Juquia River basin water resources development plan.

This plan is one of the most important projecty by DAEE (Department of Water and Electrical Energy of São Paulo State), and has three main purposes ------

water supply to the São Paulo Metropolitan Region
peak load power generation through pumped storage station
Juquia River basin flood control

I hope this report will contribute to implementation of the plan, thus dedicating to the promotion of friendly relations between our two countries.

I wish to express my deep appreciation to the officials concerned in the Brazil for their close cooperation extended to the experts.

September 1982

Kazuto NAKAZAWA Executive Director Japan International Cooperation Agency

INTRODUCTION

INTRODUCTION

The oil crisis of 1973 and 1978 have caused great change in the energy policies of the countries in the world and, while with the various estimates of natural resources, the situation regarding the energy problem is still quite unstable. The securing energy is an indispensable factor in promotion of economic growth through industrializing the economic structure so that the development of domestic energy resources to decrease or at least to conserve imported energy has been taken up as an urgent problem, and these energy resources, particularly hydroelectric power, have been vigorously developed.

On the other hand, the Metropolitan Region of São Paulo is continuously developing in accordance with the impact of intensive economical activities. Although the last census confirmed the decreasing trend in the population, its growth rate is still high and even for the long future, the population of the Great São Paulo will continue to grow, perhaps with gradually decreasing rate. So, drinking water for the incremental population, and for other uses such as industrial and commercial, has to be provided, and long terms plan is quite necessary.

Since the major water resources around Sao Paulo City are almost powerfully developed, and considering that other resources available for water supply have restraints in the future utilization related to insatisfactory quality of water, interference with irrigation, and interferences with other municipalities supply, such as Paraiba, Atibaia and Jaguari Rivers, the developments of water resources in the São Paulo Region is pointed out as the urgent problem in the near future.

According to the electric power demand and supply plans of the South-Southeast-Midwest Region in this country, the shortage of supply capacity, especially for the peaking power demand, is anticipated after 1995, and the water demand in the Metropolitan Region is also presupposed to exceed the suppliable capacity after 1995. This year, however, has a great probability to be too late looking at a water supply side because Cantareira System, actual major system, has to release much more water to its downstream, in order to mitigate the pollution and the water requirements of Piracicaba River Basin. Also, some water resources presently planned to be developed up to 1995, have limitation with regards to the high cost and interferences with irrigation, and in some cases, there are doubts if they are fully developable or not.

~1-

With such situation as the backgrounds, GOVERNO DO ESTADO DE SÃO PAULO - SECRETARIA DE OBRAS E DO MEIO AMBIENTE - DEPARTAMENTO DE AGUAS E ENERGIA ELETRICA (DAEE) have searched all the river basins around the São Paulo, and concluded by the preliminary studies, that the Juquia - São Lourenço River System is economically and quantitatively the most developable project to supply not only the necessary water for long periods, but also to generate the peak electric power.

As this system involves the complicated water supply system and furthermore the high head reversible power stations, the Government of the Federal Republic of Brazil requested the Government of Japan in 1981 to make the technical cooperations for the feasibility study, especially for the reversible power stations, in order to expedite the Juquia - São Lourenço Project. In response to this request, the Government of Japan commissioned the Japan International Cooperation Agency (JICA) to carry out the technical cooperations for the Project.

JICA sent the two engineers listed below for the Project.

TERUMI USHIJIMA	Civil Engineer	EPDC 12 Oct. 1981
		- 11 Aug. 1982
KOOJI KOJIMA	Electri-Mechanic	EPDC 14 May 1982
	Engineer	- 11 Aug. 1982

During the period of technical cooperations a large number of engineers of Departamento de Aguas e Energia Eletrica (DAEE), Eletricidade de São Paulo S.A. (ELETROPAULO), and many engineers concerned with the Project have cooperated in studying this Project.

This Report, though the studies being in progress, is prepared, as the summary or our activities, in order to make contribute for the completion of feasibility report as soon as possible.

On the occasion of submitting the Report, we wish to express our sincere gratitudes to all persons concerned for their kind and generous technical cooperations in performing the study and sincerely expect the promotion of friendly and cooperative relations between the Federal Republic of Brazil and Japan.

7th, August, 1982.

São Lourenço and Cubatão Power Stations

9

CHAPTER 1. CONCLUSION

This project is planned to develop Juquia River for the water and electric power supply by means of the series of reservoir system so that the feasibility study of all the system was judged to be difficult to be completed in a short period because of very complicated system.

Accordingly, the technical cooperation has been mainly concentrated on the demand and supply planning, studies of the water supply and electric power and the designings of the two reversible power stations named Sao Lourenço and Cubatão which can be called as the key projects of this system.

As for the studies of the above mentioned two power stations, each one alternative was only selected such as 9 units case for the former and 8 units case for the latter and has been studied aiming at the improvement of counterparts' technical abilities so that the determinations on optimum development scales of them are not obtained yet.

The present suppliable water to the Metropolitan Region of São Paulo including underconstruction facilities is 53.7 m^3 /sec which is enough to cover the water demand until 1987.

The water demand is forecast to be 89 m^3 /sec in 2000 and 177 m^3 /sec in 2040 respectively of which amounts are estimated based on the increasing forecasts on the population and water consumption per capita in the Metro-politan Region. Though many water resources have been studied to cover the above mentioned water demand, this water supply system is finally selected because other planned systems are judged to be unreasonable because of their systems involving many kinds of difficulties such as small resources to meet the water demand necessiations of high frequent construction, industrial water utilization, diffusion of sewage and irrigation, and water diversion from the Coastal Region, water pollution, and so on. According to the development plan of this Project, the water is, at first, supplied from the upper basin of this Project in accordance with the water demand until 1995 and São Lourenço Reversible Power Station is to be commenced operation in 1996 to pump-up the water of the lower basin and finally the first stage of Juquia - São Lourenço System has to be completed until 2007.

The utilized water in the Metropolitan Region is to be diverted to Billings Reservoir through the canals of Tiete and Pinheiros Rivers and by means of the two pump stations to utilize for generation at the series of Cubatão Power Stations.

-9-

In the relation to electric power circumstances, the electric power demand in the present years is steadily increasing and the average increasing rate of the electric power demand from 1981 to 2000 is forecast as 8.0% Considering that the increasing rate of electric power demand from 1991 to 2000 is supposed to be the stable increasing rate of more than 6%, the electric power demand in 1995 is anticipated as 67×10^3 MW and 352×10^6 MWH respectively of which amounts are corresponding to 3.4 and 2.9 times each comparing to those in 1981.

The large scales of hydroelectric power station including Itaipu Power Station and so on are being developed at the present to cope with the above mentioned electric power demand. Further, the electric power supply plans of 75 x 10^3 MW in 1996 and 78 x 10^3 MW in 2000 according to the published data at the present are shown to be a little shortage of reserve power and apparent shortage in comparisons with the electric power demand plans of 71 x 10^3 MW in 1996 and 92 x 10^3 MW in 2000 respectively. To meet the shortage of the electric power supply capacity, the development of reversible power stations cooperated with the above mentioned water supply system is considered to be very effective measures as contributing to the electric power supply by means of sharing in some part of the electric power supply capacity.

Furthermore, as for the supplying measures of electric peaking power to the power demand districts, the development of hydroelectric power stations with long distance of transmission line is also considered. But, in case of this development method, the distance of transmission line is too long so that the installation of reversible power stations as mentioned above which are located near the power demand is considered to be apparently more profitable than that of the power station with the long distance transmission line.

Judging from study results of the electric power demand and supply balance, in case the power demand and supply are shifted in accordance with the plan, these reversible power stations will be needed to be put into commercial operation sequentially from 1996 as shown with following table.

-10-

	São Lourenco P/S			Cubatão P/S

TABLE 1-1.1. OPERATION COMMENCEMENT YEAR FOR SÃO LOURENÇO AND CUBATÃO POWER STATIONS

CHAPTER 2

RECOMMENDATION

CHAPTER 2. RECOMMENDATION

As described in Introduction, the technical cooperation during stay in Brazil has been performed concentrating on the improvement of each counterparts' technical capabilities by means of giving the fundamental subjects to design the necessary structures for the feasibility study and requiring to solve those matters, so that the basic considerations such as damsite selection, its economical evaluation and so on have not been payed so much because of having had intentions to give as much subjects as possible for making the feasibility report by themselves.

Accordingly, some fundamental matters are described as recommendation hereinunder of which considerations are important to continue the studies of this Project.

(1) Ecological Survey

This project is consisted of many reservoir systems which are generally planned to be developed as large scales of reservoir area and dead water capacity comparing with inflow discharge and the project area is covered especially with jungle on the upper basin and with banana plantation on the lower basin so that the natural conditions may be ecologically altered after completion of the series of reservoir system.

Accordingly, the preliminary survey on the ecological view points by those kinds of expert is recommendable.

(2) Water Quality

Many reservoir systems are planned, almost of the upper basin is consisted of the jungle with marshy place, on the other hand, the series of reservoir area of the downstream excepting the reservoir of LH-2A are almost covered with the banana plantation and the organic materials of 2 - 3 m are deposited on the reservoir areas according to the field investigations and furthermore lots of houses are dotted and or concentrated especially on the downstream basin of which sewages are directly flowed down to the rivers at the present. Accordingly, the following investigations and anticipating surveys are considered to be the important matters because of this project being the most essential purpose to supply the water to the Great Sao Paulo, and the basic considerations and or the effective measures for the present reservoir

- 1 5 -

systems may be necessiated if the results of the above mentioned investigations and surveys are found out to be unreasonable.

(1) Periodical water quality investigations.

(2) Analysis of the organic materials.

(3) Anticipating surveys of reservoir water qualities in case that the vegetation and the organic materials are not removed and or only the latter nor done so.

Anyway, the vegetation and its root are considered to be at least removed from the reservoir areas.

(3) Hydrology

Though the natural inflow estimations are considered to be reasonable, the flood hydrograph to design the spillway and diversion which is adopted as 1,000 and 25 years return period flood is necessary to be reconsidered especially about the intensity distributions of regional storm rainfall.

According to the inflow to Billings and Pedras Reservoirs including the pumping up discharge, the authorized data have to be prepared for the further studies of Cubatão Compounded Reservible Power Station.

The flood control capacity of Cubatão River Canal and the necessary release discharge for the downstream of Cubatão River are expected to be determined because these items greatly give the affects to the operation rules of the existing power stations and to the studies of Cubatão Compounded Reversible Power Station.

The periodical measurements of the relation between the suspended material quantity and the natural flow are recommendable to be performed especially on both of the upper basin and the downstream of lower basin because that quantity is supposed not to be little accroding to the field investigations.

Evaporation from each reservoir is to be more carefully studied because the amount is considered not to be negligible as the reservoir area is generally big in comparison with the drainage area.

(4) Selection of Damsites

As for São Lourenço Reversible Power Station, the selection studies for upper and lower reservoirs are expected to be performed again taking

-16-

into considerations of the above mentioned ecological and water quality matters, the connection procedures of water supply system, the economical evaluation including the reservoir cleaning costs, the necessary reservoir capacities, the relation of water-way concerned and other necessary items.

On the other hand, other good damsite is judged not to be existing for the lower reservoir of Cubatão Compounded Reversible Power Station by means of the field investigations.

(5) Further Studies of Alternatives

Each one alternative of São Lourenço and Cubatão Reversible Power Stations have been only studied during stay in Brazil as described in this report so that other alternatives are earnestly recommended to be studied from now on to solve the most reasonable development scales of the both power stations.

As almost of all studying procedures have been shown, the same and or applied procedures are utilizable for these performances.

Also, the pipe line system at the upper basin is considered to be one other alternative so that this system is expected to be further studied.

(6) Geological and Construction Material Investigations

The geological investigations have been performed and some useful geological informations are obtained, but the further investigations are quite recommendable in accordance with the final selection of damsites, reservoir types and power structures, and referring the results of the field geological reconaissances.

Accordingly, the further necessary geological investigation items as the feasibility stage are already submitted by the letter on the conditions that the layouts of each structure on São Lourenço and Cubatão Reversible Power Stations are assumed to be final. Furthermore, some traces of land sliding are observed around the lower reservoirs of Dam LH-2A and Cubatão so that their distributions and scales are necessary to be geo-technically studied by the field investigations and the phenomena by the water level being up and down after completions of their reservoirs are to be anticipated.

-17~

As for the dam embankment materials, the borrow areas for each dam have to be selected considering qualities, quantity distributions, transportation conditions and so on, and the necessary field and laboratory investigations at the feasibility stage are to be executed for impervious core, filter and rock embankment materials.

According to the concrete aggregate for this Project, any special investigation is considered not to be necessary at the feasibility stage because the rock qualities around the project area are generally supposed to be sufficient to produce the aggregate.

(7) Fundamental Designing Procedures

The above mentioned items have been submitted and been studied during the technical cooperation and some further considerations and informations are submitted by the letter so that studies on this Project are quite recommendable to be progressed using and or applying the above procedures and other ones.

(8) Operation Rules

As the electric power system of Juquia - São Lourenço Project is considered to be reasonable to be planned as the same system, the weekly operation is better for Sao Lourenço Reversible Power Station to make as longer generation hours a day as possible during the economical lives, though the necessary reservoir capacities for the generation are increased.

On the other hand, the series of pump station are not operated during the generating times, and further, the designed pumping up capacities have to be determined considering the actual generation hours a year and the periodical repairment and accident rates, but in the case of the latter, the full pumping up operations will be necessary.

According to Cubatão Compounded Reversible Power Station, the reservoir capacity of Pedras is limited so that the daily operation is considered to be reasonable.

(9) Firm Discharge

The firm discharge is now considered as the regulated minimum discharge in the reservoir during the driest period, but it is

-18-

considered to be one other procedure that the average dischage of the first and second driest periods is adopted keeping the necessary reservoir capacity for the driest period, because this kind of the driest period will not occur so often in future, and it will be possible to require to the consumers to save the water consumption during such driest period.

(10) Compensation Costs

The compensation costs such as land, land right and so on are recommendable to prepare the figures showing relation between the elevation of reservoir and the total compensation costs.

The compensation costs by the decreased hydroelectric energy at CBA's Power Stations for the development of upper basin is to be estimated and negotiated with the organization.

- (11) As for the Reversible Power Station, it is quite important to study the basic plan of the daily and or weekly operation rules in accordance with the peaking power demand considering the forecast demand duration curves.
- (12) The electric power systems in south, southeast and midwest regions of Brazil are composed of those of some electric power companies. The both Reversible Power Stations are designed to be connected with the electric power systems of other electric power companies by reason of distance from reversible power station to substation, voltage of transmission line and so on.

Generally, in case of the installation of large capacity power station at the base of complicated power systems, the enough grasp of conditions in power systems is necessary.

Especially, as for the installation of these two large capacity reversible power stations, analysis of power system about output and input of power is executed and then the stability such as static and transient of the power system is necessary to be studied in detail.

(13) In case of the plan of reversible power station, the necessity of cynchronous condenser operation is recommendable to be studied from the view of voltage regulation on power system.

-19-

- (14) The improvement and or extension of the existing substation being connected with reversible power station have to be studied in accordance with the capacity of reversible power station.
- (15) As for the development study of Cubatão Compounded Reversible Power Station, detailed study of revolving speed of pump-turbine and voltage of generator-motor is further necessary including stability and economy of machine.
- (16) The reasonable type such as Francis or Diagonal types and the unit capacity of each pump station have to be carefully selected after studying in detail not only effective head and pumping discharge but also efficiencies, economies, methods of operation and maintenance and so on.

Chapter 1. General Situation

1.1. Physical Features.

Covering an area of $8.5 \times 10^6 \text{km}^2$ (inland waters $55,000 \text{ km}^2$) - 47% of the South American Continent, Brazil ranks among the five largest countries in the world.

Extreme points are defined by parallels 5°16' 19" N and 33°45' 09" S and meridians 39°45' 54" and 73°59' 32" WGr.; the major part of the territory is located between the Equator and the Tropic of Capricorn. The predominant portion of Brazilian boundaries is the eastern seacoast of the Atlantic Ocean with extension of 7,400 km and all other South American Countries excepting Chile and Equador have frontiers in common with Brazil.

Brazilian territory consists of 41% of lowlands, 58.5% of highlands with heights up to 1,200 m and only 0.5% of lands with altitudes over 1,200 m. The hydrographic basin is divided into nine and the Amazon Basin occupies 47% of country, followed in order by the Parana, Northeast, Tocantins-Araguaia, São Francisco, East Paraguai, Southeast and Uruguai Basins.

As to hydraulic potential, the Parana Basin (46,000 MW) and the São Francisco Basin (15,000 MW) have leading positions while other river basins are under 8,000 MW.

Brazil is divided into five regions which in turn are subdivided into 27 political units comprising 22 States, 4 Federal Territories and the Federal District, seat of the government, where Brasilia City is located.

Five main climatic zones are typical in the country; hot and humid climate in the Amazon Rainforest, with an average temperature $24-26^{\circ}$ C the year round and rainfall 1,700-3,000 mm, hot and humid climate in the Tropical Forest with rainfall 1,000 - 1,700 mm; hot and semi-humid in the Cerrado with 1,500 - 2,000 mm; moderately warm and humid climate in the middle latitudes with annual rainfall 1,500 mm and temperature ranging between 20°C and 14°C.

In the last zone, temperatures reaches minimum of -8° C from the coast to the upland and maximum over 40° C in the low inland areas.

-27-

1.2. Population.

The last census (1980) resulted for Brazil's total population 119,100,000 inhabitants constituted by 67% and 33% for the urban and rural population respectively.

The geometric mean rate of annual growth per 100 persons observed for the last decade was 2.48 and the population density 14.08 inhabitants/km². The Table II-1.1 shows the general distribution of the population in the country for each great regions.

Region	Population (inhabitants)	Geometric mean of rate of annual growth (per 100 persons) 70/80	Population density (inhab/km ²)
North	5,890,000	5.05	1.66
Northest	34,860,000	2.16	22.60
Southeast	51,750,000	2.64	56.32
South	19,040,000	1.43	33.87
Center-West	7,560,000	4.05	4.02
Brazil	119,100,000	2.48	14.08

Table II-1.1 - Distribution of Population for each Great Regions.

The heavy concentration of the population and social-economic activities that have occurred in a number of urban nucleus have resulted in population growth beyond the boundaries of the main cities increasing in excess of the population of metropolitan areas. The Table II-1.2 presents the evolution of 9 (nine) metropolitan areas in which 34.5 million inhabitants almost 30% of total population of the Country are concentrated.

-28-

·						
Metropolitan Areas	Popula (inha		Geometric mean of annual Growth. rate (per 100 per~	Area (km ²)	Population density

Curitiba	820,766	1,441,743	5.80	8,763	165	
Belém	656,351	1,000,349	4.30	1,221	819	

Table II.1.2 Evolution of Population in the Metropolitan Areas of Brazil.

The economically active population is distributed by activities in agriculture 32%, industry 24%, commerce 10%, services 15%, transport and communications 4% and others 15%.

About the religion, 95% are Christian, and the people is constituted mainly by Portuguese, Italian, Spanish, German and Japanese descendants.

-29-

1.3. National Economy.

The energy crisis which intensified world inflation and unemployment has also had effects on the Brazilian economy.

The general price index (according to criteria on internal available assets) which by definition reflected the country's degrees of inflation, increased to 95.2% during 1981. The increase in 1980 was 110.2%. The balance of payments showed US\$ 1,207 x 10^6 surplus in 1981 after registering US\$ 2,928 x 10^6 deficit in the preceding year.

The growth rate of Brazilian economy decreased from 7.9% in 1980 to -3.5% in 1981.

Examined by sectors, the 1981 product growth rate shows the following values: agriculture 6.8%; industry -8.4%; commerce -6.0%; transportation and communication 0.8%. In 1980 the increased were 6.3%; 7.9% 8.0% and 10.8% respectively.

The increase of inflation during 1981 can be partially explained by the readjustments that were in respect to petroleum products and their associated cumulative effects.

In reference to the financial performance of the country, there were surpluses of US\$ 38×10^6 and US\$ 33×10^6 in 1980 and 1981 respectively. Improved efficiency of tax collection procedures, the normal increase of population subjected to taxation, the acceleration in the rate of inflation as well as the favorable performance of the country's economic sectors of activity resulted in an increase of federal receipts from US\$ $23,131 \times 10^6$ in 1980 to US\$ $24,319 \times 10^6$ in 1981. On the other hand, expenditures during the years were US\$ $23,101 \times 10^6$ and US\$ $24,286 \times 10^6$ respectively.

Several subsequent mini-devaluation of exchange rate were realized between Brazilian money (cruzeiro) in relation to US dollar with the worsening of the world economic crisis and the increase of domestic prices we well as other factors and a total accumulative percentage was 95.3% in relation to US dollar in 1981. The following table shows the main data about Brazilian economical situation during the last four years.

ITEM	Unit	1978	1979	1980	1981
Gross National Product	10 ⁹ US\$	201.85	226.15	240.99	273.33

Table II-1.3 Brazilian Economical Activity.

1.4. Energy Resources.

Electric energy especially hydraulic and alcohol energies are at present actively being developed aiming at industrialization of Brazil. The present energy resources consumption, as indicated in Table II-1.4, shows that 39.1% of total consumption is of petroleum.

Primary Energy	Production	Importation	Exportation	Total Consumption	Rate of Energy
Petroleum	9,083	43,485	60	54,319	39.1
Natural Gas	2,022			1,112	0.8

Total	91,723	46,819	60	139,047	100.0

Table II-1.4 Balance of Primary Energy in PEt (1980)

The electric power supply facilities in 1980 are totaled as 31,735 MW (120,720 GWh) with the ratio of composition between hydraulic and thermal being 85.9%: 14.1% and the electric energy consumption per capita was 1006 kWh.

It is forecast that power demand will grow at an annual rate of 8% untill 2,000. Hydraulic potential possible to be developed is estimated as 213,000 MW as shown in Table II-1.5 with only 15% presently developed, and this means that Brazil has a lot of hydraulic energy.

Name of Region		Hydraulic Potential (MW)					
Hand of Hebron	Total	Operation	Under Construction (80 to 85)				
North	97,800	705	2,640				
Northeast	15,500	4,091	3,301				
Southeast	56,200	21,497	4,050				
South	43,500	4,470	11,756				
Center-West	(*)	589	(*)				
Total	213,000	31,735	21,747				

Table II-1,5 Hydraulic Potential in Brazil,

(*) included in the North or Southeast Regions.

The Brazilian's programme of alcohol foresees the production of 10.7 million m^3 in 1985 of ethilic acohol, utilizing as the raw matherial basically the sugar cane with the following purposes:

6.1 million m^3 of hydrous alcohol to supply alcohol motor vehicles. 3.1 million m^3 of anydrous alchol to add till 20% in the gasolin. 1.5 million m^3 for the chemical industries consumption.

With regard to petroleum, 84% of the total processed of 63.2 million m³ is presently being imported, so that intensive expolitations in sedimentary areas and along the continental shelves are being executed and the most prominent fields are along the continental shelves of the State of Bahia, Rio de Janeiro, Sergipe, Espirito Santo and Rio Grande do Norte.

Promising petroleum and natural gas deposits by means of initial well drillings and sismographic, aero-magnetometric and photogrammetric surveys of geology are prospected as 213 x 10^6 m³ and 52.5 x 10^9 m³ respectively.

In respect to the pyrobetuminous schist, Brazil has several prospected reserves such as in the Parana and Rio Grande do Sul States totalizing 672 x 10^{6} m³. Mineral coal such as lignite is deposited in the South Region especially in the States of Rio Grande do Sul and Santa Catarina, where the deposits are estimated to be 22.6 x 10^9 ton.

The deposits of uranium ore are also prospected to be 236×10^3 ton and nuclear power stations with total installed capacity 10,500 MW in 2,000 are being developed and planned as well as mining and enriching of uranium.

In any event, Brazil was severely hit by the energy crisis because of petroleum importing country. For this reason, developments of natural abundant energy resources are expected to be the most important matters to stimulate and develop economic activities in the country.

CHAPTER 2. PRESENT STATE OF ELECTRIC ENTERPRISES.

2.1 Electric Power Situation in Brazil.

According to existing energy sources and to energy market conditions, Brazil is usually divided into 5 groups of states with integrated electrical systems, either existing or planned, forming regional power systems of great extension in area with similar economic features. These regions are:

 North Region: States of Para, Amazonas, Acre, Amapa and Rondonia.
 Northeast Region: State of Bahia, Alagoas, Sergipe, Pernambuco,

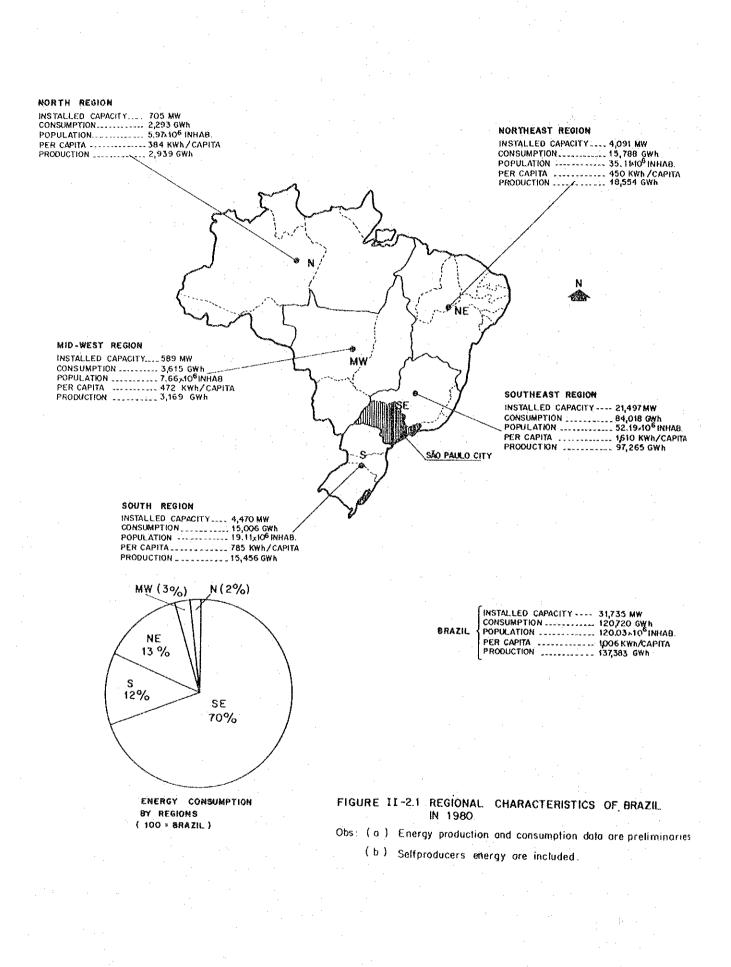

Paraiba, Rio Grande do Norte, Ceara, Piaui and Maranhao.

- Southeast Region:	States of Espirito Santo, Rio de Janeiro,
	Minas Gerais and São Paulo.
- Midwest Region:	States of Mato Grosso, Mato Grosso do
	Sul, Goias and Distrito Federal.
- South Region:	States of Parana, Santa Catarina and Rio
	Grande do Sul.

For the energy market studies, the South-Southeast and Midwest Regions (to be indicated in this report by S/SE/NW simbols), have to be analysed all together because there are too much interdependency among them, through the interconnection of transmission lines and energy transferences. The importance of the S/SE/MW Regions is so that 65% of total population and 85% of energy consumption are concentrated in this region, as indicated in Figure II-2.1.

General informations about the Brazil and the main enterprises are mentioned in next items, with special emphasis for this region.

The trends in installed capacity and gross generated energy in Brazil are indicated in Table II-2.1 and II-2.2 and Figure II-2.2. The installed capacity in 1980 was a total of 31,735 MW with 85% of the facilities consisting of hydraulic and 15% of thermal. The total gross annual electric energy production is 137.38 TWh of which 92% is due to hydroelectric power generation. The per capita energy production are variables from 384 kWh in North Region to 1610 kWh in Southeast Region with an average value of 1006 kWh, as indicated in Figure II-2.1.

-- 4 0 --

÷

The per capita consumption level is not on the high side but growth rate in energy production is high, with 1970-1980 average exceeding 11% a year. It is surmised that such a trend is partially due to the first and second National Development Plan started in the beginning of years 70, and although restraints in the petroleum utilization have been forced since 1974, the policies to substitute fuel by electricity and the stimulus for the industries with intensive utilization of electricity, have been responsible for the continuity of such a high growth rate.

However, the year 1981, although based on preliminary data, shows that it was a typical year with 3.4% negative growth rate in the Gross domestic Product as a result mainly of inflation control policy. Although this growth rate is supposed to return gradually to its general tendency, up to about 4% in the year of 2000, its effect has taken into account for the demand forecast, as explained in Chapter 1 of Part III. According to this forecast, Brazil, for example, is aiming at the generated energy to be increased to 5.5 times of the present capacity until 2000.

(*) Estimated value

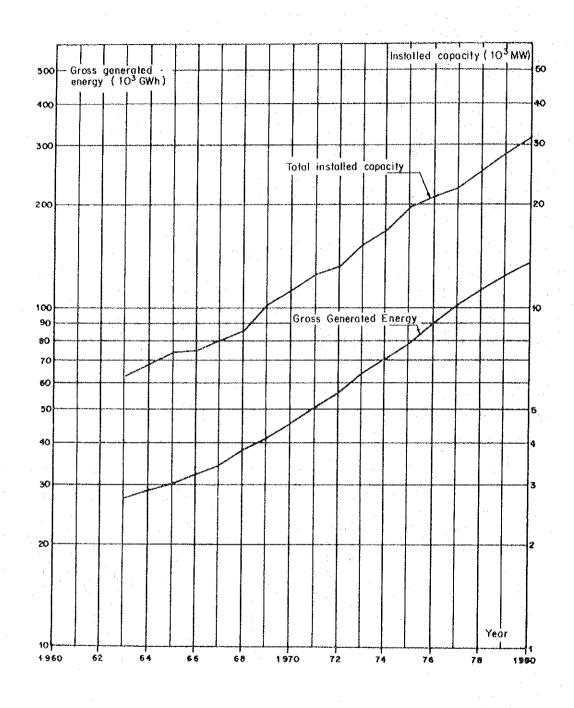

FIGURE II-2.2 INSTALLED CAPACITY AND GENERATED ENERGY IN BRAZIL

-44--

Particularly for the South/Southeast Midwest Region, this will be increased to 4.7 times of the present production and large scale hydro-power stations are scheduled to be commissioned such as Foz do Area (2,460 MW), Segredo (2,100 MW), Salto Santiago (1,998 MW). Ilha Grande (2,000 MW Itaipu (12,600 MW) and others up to 1995. Also in 1982, the first nuclear power station (626 MW) is planned to go into operation, and 8 additional nuclear power stations are planned to complete with 10,586 MW up to 2000. However, during the period 1995-2000, the electric power development plans are not complete and so that electric energy has to be increased by means of development of other new power stations, probably from North or South Region depending on future cost analysis. Also for the maximum demand supply of the S/SE/MW Region, pumped storage power stations are judged to be necessary so that, São Lourenco (2835 MW) and Cubatão III (2400 MW) MW) Power Stations are planned to be commissioned in 1996 and 1998 respectively.

The ratio of energy consumptions by consumers category, in 1980, were 58% for industrial use, 19% for general household and 11% for commercial as indicated in Table II-2.3. These ratios have not changed so much curing the past 10 years.

TABLE 11-2.4 MAJOR HYDROELECTRIC POWER STATIONS IN OPERATION AND UNDER CONSTRUCTION (DEC.81)

C: Under construction

OP: in operation

-46-

The major hydro-power stations in Brazil in operation and under construction are indicated in Table II-2.4.

In the North Region, there are several small municipalities or villages supplied by diesel units. A plan to substitute diesel oil by alcohol, vegetal coal, or firewood, is on course, and in some cases, the small hydroelectric power stations are also under planning stage.

The major transmission network is composed of 500 KV (6,785 km) and 440 kV (4,624 km) transmission lines in 1980. Voltages of 345 kV (6,677 km) and 230 kV (19,868 km) are also commonly adopted and 138 kV, 88 kV, 69 kV are adopted for local transmission. The introduction of 500 kV system to the major network has been going on since 1974 and at present, there are under construction of the 750 kV-AC and  $\pm$  600 kV-DC from Itaipu Power Station (12,600 MW) to the São Paulo Metropolitan Region.

Table II-2.5 indicates the annual trends in lengths of transmission lines and Table II-2.6 indicates the main characteristics of the transmission lines from Itaipu to São Paulo (Sao Roque and Tijuco Preto Substations).

### 2.2. Electric Enterprises.

The electrical industry of Brazil is almost entirely operated in the form of Governmental ownership with electric power administration and the jurisdiction of the Ministery of Mining and Energy (MME) through the Water and Electrical Energy National Department (DNAEE). However, the organization of the companies is complex and it may be separated into two main groups as below:

ELETROBRAS (CENTRAIS ELETRICAS BRASILEIRAS S.A.) GROUP:

FURNAS: Furnas Centrais Electricas S.A.
CHESF - Companhia Hidroeletrica do Sao Francisco
ELETROSUL - Centrais Eletricas do Sul do Brasil S.A.
ELETRONORTE - Centrais Eletricas do Norte do Brasil S.A.
LIGHT - Light Servicos de Eletricidade S.A.

OTHER GROUP: The main companies are:

CESP - Companhia Energetica de Sao Paulo S.A.

CEMIG - Centrais Eletricas de Minas Gerais S.A.

COPEL - Companhia Paranaense de Energia Eletrica.

CEEE - Companhia Estadual de Energia Eletrica do Rio Grande do Sul.

CPFL - Companhia Paulista de Forca e Luz. ELETROPAULO - Eletricidade de Sao Paulo S.A.

The first group is the federal ownership and the areas directly handled by them are indicated in Figure II-2.3. Although all the country is covered by federal ownership, there are some cases in which the state companies have control of their respective state area, that is the second group mentioned above, such as CESP, ELETROPAULO and CPFL for São Paulo State, and CEMIG for Minas Gerais State.

ELETROBRAS is a holding company established in 1962, with the purpose of planning and financing the electrical energy program of the country and also the co-ordination of accomplishment. At present ELETROBRAS has about 2,100 employees and the main activities are the control of the electrical companies, co-ordination of interconnected systems and the general planning.

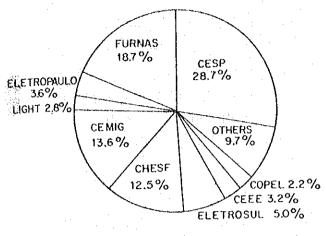

obs: Shaded area indicates São Paulo State.

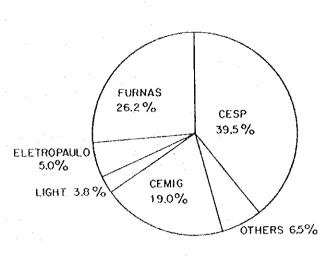

FIGURE 11-2.3 MAIN ELECTRICAL COMPANIES CONTROLED BY ELETROBRAS

In the South-Southeast-Midwest, there are a high concentration of the population and industries which are responsible for 82% of total energy consumption in Brazil. In this region, São Paulo state is mainly supplied by CESP and ELETROPAULO, and CEMIG and FURNAS supply mainly to Rio de Janeiro and Minas Gerais State.

Figure II-2.4 indicates the contribution of the major companies in the total energy production when compared with the total gross energy produced in Brazil, Southeast Region and São Paulo State in 1980.

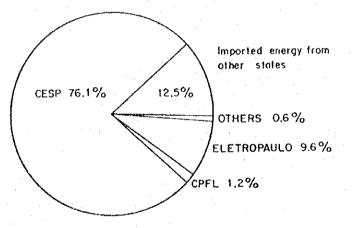

-50-

BRAZIL - TOTAL PRODUCTION : 137.4 TWA (1980)

SOUTHEAST PRODUCTION: 97.3 TWN (1980)

SAO PAULO STATE - 1 980 • Total energy consumption = 50.511WA

FIG. 11-2.4

GROSS ENERGY GENERATED IN BRAZIL AND THE ENERGY GENERATION IN THE MAJOR COMPANIES ~ 1980.

So, almost 53% of energy generated in South Region, or 37% of Brazilian production, is consumed in São Paulo State which has 22% of population of all the country.

It is important to observe that although ELETROPAULO production is only 9.7% of total consumption of São Paulo State, its distribution area requires 64% of the energy consumed in Sao Paulo State. This is because the São Paulo Metropolitan Region with its 12,500,000 inhabitants and the industrial area of Paraiba river valley along the São Paulo-Rio de Janeiro roadway are included in the distribution area of ELETROPAULO, as indicated in Figure II-2.5.

-51-

Three main companies are responsible for the energy generation and distribution in São Paulo State, that is CESP, CPFL and ELETROPAULO. At present CPFL is a subsidiary company of CESP, and also there are other regional or municipal organizations supplying the energy, but its generation capacity is almost negligible compared with these 3 companies.

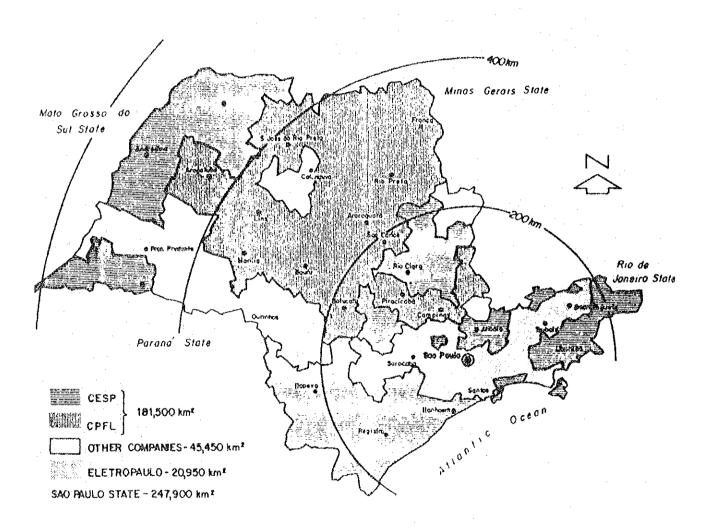

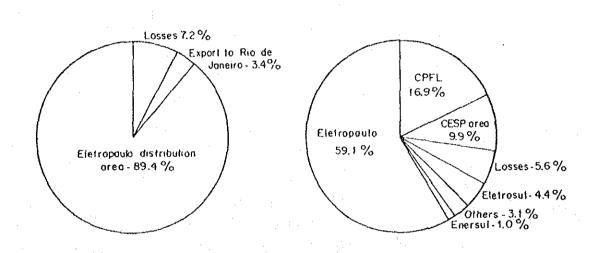

FIGURE 11-2.5 POWER DISTRIBUTION IN SÃO PAULO STATE

CESP is a State enterprise established in 1966 with 25,000 employees, and it is connected with the Secretary of Public Works and Environment, through the Department of Water and Electric Energy (DAEE) that is the representative of São Paulo State Government. In 1975, CESP took control of the CPFL Company.

ELETROPAULO is also a state enterprise established in 1981, and formerly known as a LIGHT-Electricity Co., which was one of the oldest energy enterprise in Brazil supplying the two main metropolis, Rio de Janeiro and Sao Paulo. At present ELETROPAULO is connected with the São Paulo State Government through the Department of Water and Electric Energy-DAEE, and the remaining LIGHT is under the ELECTROBRAS control, s supplying Rio de Janeiro, and is known as LIGHT-Rio.

The energy generation and distribution among these companies and the percentual contribution of each one is indicated in the Figure 11-2.6.

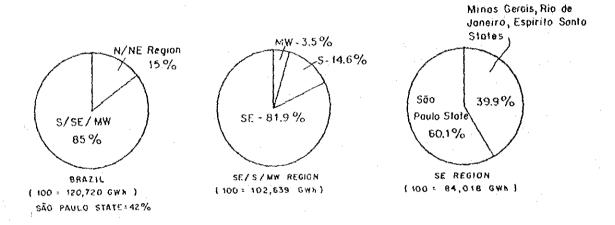

FIGURE 11-2.6. ENERGY DISTRIBUTION OF CESP AND ELETROPAULO SYSTEM IN 1980.

-53-

Present State of demand and supply of electric power in São Paulo State,

As mentioned before, CESP and ELETROPAULO electric system is one of the most representative of Southeast region, as they control more than 85% of this region.

The weight of São Paulo State is indicated in Figure II-2.7 which shows that it represent 50% of total energy consumed in S/SE/MN Region, and 42% of total energy used in Brazil.

ENERGY DISTRIBUTION IN SÃO PAULO STATE, FIGURE II-2.7 SOUTHEAST RECION, AND S/SE/MW REGIONS-1980

With regard to the São Paulo State, the trend in energy generated is indicated in Table 11-2.8. The average growth rate of energy generated in the past 10 years, was 13.1% and the amount of energy generated, 3.4 times of 10 years ago.

Usually the period from August to December is the maximum demand period for South-Southeast-Midwest Region and it depends on each distribution area. Rio de Janeiro city for exmple has the maximum demand on December, meanwhile Sao Paulo city is on August. Figure 11-2.8 indicates the monthly percentage of peak with regard to the yearly maximum demand. As indicated, there is not very much difference between the smallest maximum demand, with the range of 77 % to 86%.

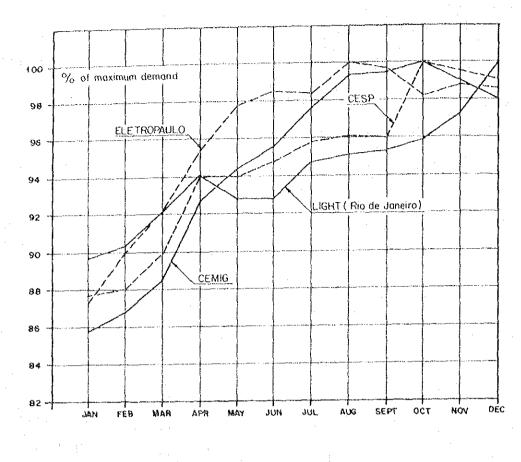

FIGURE 11-2.8 MONTHLY VARIATION OF MAXIMUM DEMAND

With regard to the daily demand curve it is indicated in Figure II-2.9 and Table II-2.9 some typical curves for CESP and ELETROPAULO systems in September, 1980. The demand curve for the São Paulo State Southeast Region, and South-Southeast-Midwest Region is indicated in Table II-2.10, that was obtained indirectly considering the ELECTRO-PAULO and CESP demand curve, and also the relationship between their generated energies with regard to these regions.

As the CESP system is the most representative for São Paulo State, Table II-2.11 indicates the trends in annual demand and supply balances of the power system of CESP.

Chapter 3. Present State of Water Enterprises

3.1. Water Supply Situation

3.1.1. General Considerations

The Metropolitan Region of São Paulo is constituted with 37 municipalities covering an area of 7,951 km² and its total population is 12,500,000 inhabitants according to the last 1980 Census. Almost of this population is concentrated in the Upper Tiete Besin (upstream from the Pirapora Dam) with 5,720 km² of Drainage area corresponding to 75% of total area of Metropolitan Region of São Paulo.

The social - economical importance of the Metropolitan Region compared with the Brazil is presented in the Table II-3.1.

TABLE 11-3.1 SOCIAL - ECONOMICAL PARTICIPATION OF THE METROPOLITAN REGION IN RELATION TO THE SÃO PAULO STATE AND BRAZIL.

Discrimination	Relation to		
DISCLIMINATION	São Paulo State	Brazil	
Population	50%	10%	
Industry Activities	62%	27%	
Personal occupied in the			
Industries	71%	36%	
Industrial Transformation			
value	72%	40%	

With regard to the water supply system of Metropolitan Region of São Paulo, it is divided into the two modalities of attendances named "Integrated System" and "Isolated System".

The "Integrated System" is constituted with production systems interconnected with a complex adducer system named "Metropolitan Adducer System". This System is operated by SABESP and attends 28 municipalities. The remaining 9 municipalities of Metropolitan Region are supplied by individual system or "Isolated System". The total nominal capacity of the production system is nowadays 31 m³/s and the "Metropolitan

Adducer System" is constituted with 1000 km of adducer and 1,400,000 m³ of reservation capacity. In the municipalities supplied by SABESP the total length of water system is 14,000 km and 1,400,000 domiciliary connections to supply 8,500,000 in-habitants (September 1979).

The Tables II-3.2 and II-3.3 presentes the situation of each municipality supplied by SABESP (September/79)

### 3.1.2. Existing Water Supply Plans

The São Paulo State Government, through Departmento de Aguas e Energia Eletrica - DAEE, in 1968 developed the "Plano Director de Obras para Desenvolvimento Global dos Recursos Hidricos das Bacias do Alto Tiete e Cubatao", known by "HIBRACE PLAN".

The HIBRACE PLAN foresees the water utilization of upper Tiete and neighbourhood basins to supply the prospected demand of Metropolitan Region of São Paulo with 72 m 3 /s up to 2000.

The following facilities showed in the Table II-3.4 were planned in this Plan and the prospected water demand is presented in the Table II-3.5.

Planned System	Supply Capacity (m ³ /s)	
Alto Tiete	19.6	
Guarapiranga	38.0	
Cantareira	30.0	
Billings	10.0

TABLE TI-3.5 PROSPECTED WATER DEMAND FOR THE METROPOLITAN REGION OF SÃO PAULO (HIBRACE PLAN - 1968)

In 1976, The "Companhia de Saneamento Basico do Estado de São Paulo"-SABESP", based on new data developed the "Plano Director de Suprimento de Agua Potavel da Regiao Metropolitana de São Paulo". The results of this study are presented in the Table II-3.6.

TABLE 11-3.6PROSPECTED WATER DEMAND FOR THE METROPOLITANREGION OF SÃO PAULO (SABESP PLAN - 1976)

YEAR	Total Population (Inhab.)	Supplying Population (Inhab.)	Average Demand (m ³ /s)	Average Per Capita Consumption (1/Inhab day)	
1980	12,461,000	11,201,000	. 37	282	
1990	17,876,000	16,429,000	65	341	
2000	23,626,000	22,435,000	104	400	

3.2. Water Supply Enterprises

The water supply enterprise of the Metropolitan Region of São Paulo (SABESP) is entirely operated in the form of state ownership. It is under the jurisdiction of the Secretary of Public Works.

In the past, all the municipalities had its particular water wupply enterprises, but in attention to a governmental policy, SABESP incorporated almost all the municipal water supply enterprises of Sao Paulo State,

SABESP is an organ established in 1973 and has the main purpose of construction and operation of facilities for water supply and sewerage treatment. SABESP has several regional departments throughout the state and a total numbers of 16,800 employees.

#### 3.3. Water Supply Facilities

Nowadays, the water supply system of Metropolitan Region of Sao Paulo serves 85% of the total population, by the use of superficial resources as shown in the Table II-3.7.

Name	Firm Discharge(m ³ /s)
Guarapiranga	10,5
Cantareira (1 st stage)	11.0
Rio Grande (BILLINGS)	4.1
Others	2.1
TOTAL	31.7

TABLE II-3.7 WATER SUPPLY SYSTEMS DEVELOPED BY SABESP

Presently, SABESP is concluding the final stage of Cantareira System that will add 22 m³/s to the supply system. Then, the total available discharge for the Metropolitan Region will be 53.7 m³/s, which is enough to cover the demand until 1987, according to the prospected water demand by SABESP PLAN in 1976.

## 3.4. Supply and Demand Situation of Water

After 1987, SABESP foresees the utilization of new recources for the supply of Metropolitan Region. According to the plan developed in 1976, these new resources are described in Table II-3.8

chapter 1. Demand and Supply Forecast of Electric Power

#### 1.1. Demand Forecast.

As presented in the Chapter-2, water demand forecast and supply analysis made for the São Paulo Metropolitan Region, indicates that, water from São Lourenco River will be required in 1996, and it is necessary to construct the large scale pumping station (525 m effective head) to make possible the supply of drinking water to São Paulo Area, which is situated more than 700 m above sea level.

Especially for this pumping station, the present plan is recommended as a reversible power station, named São Lourenco, which has an advantage to be useful for the water supply side as a pumping station, and for the electric power side, mainly as a power station for the peak power generation. On the other hand, once this water of São Lourenco River is utilized, it will return to the natural drainage system of São Paulo Area, which is mainly based on Tiete, Tamanduatei and Pinheiros Rivers. These rivers are closely related to the ELETROPAULO Hydroelectric System, which has a diversion works to the seaside region through hydroelectric power stations of Cubatao I and II (700 m head) in full operation since 1950 (first unit in 1926) and 1961 respectively. In the future, through the gradual development of São Lourenco River to supply the water to São Paulo, much more utilized water will be available, and another reversible power station named Cubatao III is planned to make the effective utilization of this incremental water and to get advantage of the peaking power generation for power demand districts, of which power station is to contribute for the energy recovery of the electric power system from the view point of energy balancing.

The purpose of this chapter is to analyse the electric power demand and supply balance for the future, and to indicate the year of operation commencement of these power stations.

Electric power demand forecasts are roughly divided into longrange or short-range forecasts depending on the number of years considered. For the construction of the structures such as São Lourenco and Cubatão Reversible Power Stations, mainly considering that this kind of power stations is the first in Brazil, it is supposed that a minimum of 10 years hence will be required including the preparatory period. For the water supply side, a demand forecast up to 2040 is

-83-

considered, and even for electric power side, a demand forecast beyond 2000 is desirable, but this kind of study is considered to be very complex and difficult, mainly because the trends of international energy situation, and the evolution of the world and domestic economies are very difficult to forecast. Consequently, in this report, for the electric power side, a demand forecast up to 2000 is made, and from the view point of demand and supply balance, it is judged that the operation commencement years of São Lourenco and Cubatão Reversible Power Stations will be necessary before 2000.

The water supply side is taken into account of only the São Paulo Metropolitan Region to analyse the demand and supply of drinking water. However, the electric power side has to be considered all the South Southeast and Midwest Region of Brazil, even for the planning of the peak power generation, because these regions are interconnected or will be interconnected by transmission lines in order to compose an integrated electrical system.

The contents of this Chapter consist of four items, that are the outline of the demand forecast made by ELETROBRAS in 1981, named PLAN 2000, the forecast made by applying an equation over the energy basic data, the longrange forecast made by a macro-method and, finally, the results of present study.

### 1.1.1. Demand Forecast by ELETROBRAS

This paragraph is a summary of the report "Plan to supply the electric energy requirements until 2000", or simply "PLAN 2000", published in March 1982 by ELETROBRAS- Centrais Eletricas Brasileiras S.A., following the guidelines of the Ministry of Mines and Energy.

Historically, the behavior of the electric energy market in Brazil may be characterized by the high annual average rates of growth of the consumptions above 10% verified in the last 10 years period. Until 1974, the evolution of the requirements of overall energy and electric energy followed up to growth of GDP (Gross Domestic Product). Since then, due to the restraint of the use of petroleum products, alternations of the industrial production structures with increase of electric energy utilization to substitute fuel energy at the lower degree were promoted and the growth of the requirements of overall energy decreased following the evolution of GDP. While, until 1980, the growth of the con-

~ 84 -

sumption electric energy was maintained at the level of the beginning of the previous ten years as shown in Figure III-1.1.

The plan of Plan 2000 is maintained near to and below the previous plan named Plan 90, such as the demand for the 1981-1984 period being quite typical in comparison with previous trends.

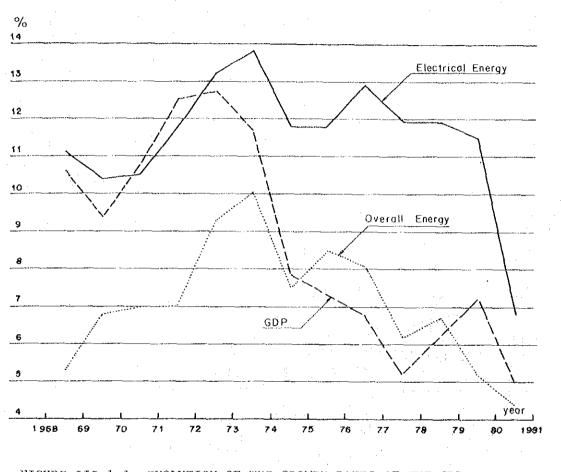

FIGURE III-1.1 EVOLUTION OF THE GROWTH RATES OF THE GDP, OVERALL AND ELECTRIC ENERGY

Notes: (a) Growth rates considering biannual movable average values.

- (b) Overall energy includes electrical energy, and other energy sources such as petroleum, coal, gas and etc.
- (c) GDP Gross Domestic Product, or P1B-Produto Interno Bruto, is close to the values of GNP - Gross National Product in the case of Brazil.
- (d) Source: PLAN 2000 ELECTROBRAS.

Table III-1.1 summarizes the evolution foreseen in the period 1980/2000, of the total electric energy required in Brazil and in the regions that are considered for planning purposes, according the estimations made by ELETROBRAS.

TABLE III-1.1BRAZIL AND REGIONS - AVERAGE FORECASTS FOR THEENERGY REQUIREMENTS, MADE BY ELETROBRAS

				(unit: C	W year)
Planning Regions	1980	1984	1990	1995	2000
North plus Maranhão	0.3	0.6	2.8	3.9	5.2
Northeast minus Maranhão	1.7	2,4	4.9	6.9	9.2
Southeast plus Mid- west minus Mato Grosso do Sul	10.3	13.3	21.4	29.8	40.4
South plus Mato Grosso do Sul	1.9	2.8	5.7	8.3	11.4
Brazil	14.2	19.1	34.8	48.9	66.2

(GW year = 8760 GWh)

Especially for the South, Southeast and Midwest Region, which includes the São Paulo Metropolitan Region, the results of the PLAN 2000, considering a load factor between 63.9% and 65.4%, and a reserve of about 15%, can be summarized as follows:

-- 86---

Year	Gross ene	rgy required	Maximum Demand
	(GWh)	(MWyear)	(MW)
1980	106,950	12,200	21,960
81	114,570	13,070	23,520
82	122,810	14,010	25,210
83	131,670	15,020	27,030
84	141,130	16,100	28,970

2000	454,080	51,800	91,080

TABLE III-1.2. RESULTS OF DEMAND FORECAST MADE BY ELECTROBRAS FOR THE S/SE/MW REGION OF BRAZIL. .

Obs.: Maximum Demand (including reserve) and the yearly values are calculated from data available in PLAN 2000 -ELETROBRAS.

- 87-

1.1.2. Demand forecast by analysis of trends.

A method using gross energy consumption obtained from the past trends is also applied in estimation for the period 1981-2000. In this method, an equation is derived from data on gross energy consumption for the period 1961 - 1980, and the most suitable equation for these data is the Gompertz equation and the results can be summarized as follows:

# TABLE 111-1.3AVERAGE FORECASTS FOR THE ENERGY REQUIREMENTSBY GOMPERTZ'S EQUATION

Year	Gross Energy required 10 ³ GWh	Gross Energy required (MWyear)
1979	91.7	10,460
1982	123.2	14,050
1895	160.5	18,310
1988	203.9	23,260
1991	253.2	28,880
1994	307.4	35,070
1997	366.4	41,800
2000	430.2	49,080

(MWyear = 8760, MWH)

1.1.3. Demand forecast by Macro-Method.

Although the ELETROBRAS-PLAN 2000 is based on Macro-Method, a forecast by this technique is again attempted considering the period 1965-1981. The main purpose is to find out what kind of difference in trend is produced between the above mentioned forecast results and those macroscopic technic reviews.

a) Consideration about the demand forecast based on GDP:

It is established statistically that there is a correlation between the energy demand and the national economy of the country. Particularly, it is clarified that a fairly regular correlation exists between GNP (Gross National Product) and the kWh Generated,

-88-

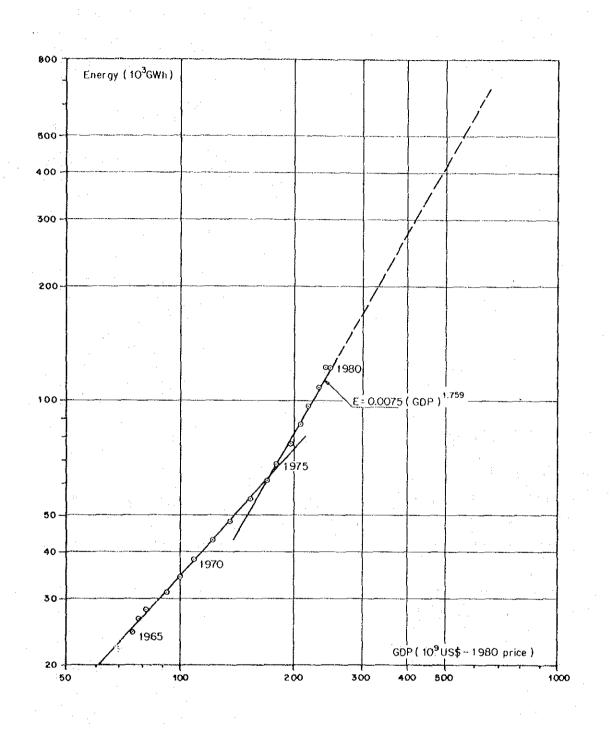

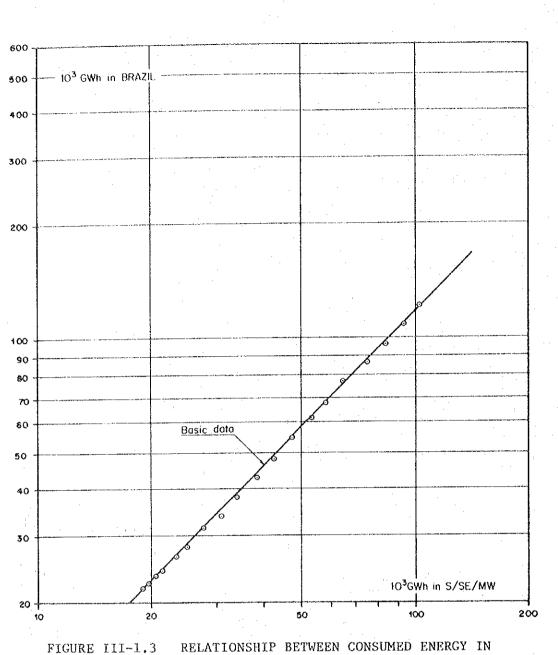

FIGURE 111-1.2 CORRELATION BETWEEN GDP AND CONSUMED ENERGY IN BRAZIL

-89-

BRAZIL AND ITS S/SE/MW REGION

and many cases of demand forecasts are made by macroscopic method based on GNP. For the case of Brazil, the GDP (Gross Domestic Product or PIB - Produto Interno Bruto) is considered instead of GNP, because this is nearly same value as GNP, and the GDP is much more representative of the economical activity in Brazil.

At first, the study is made for all of the Brazil, and after then, a correlation showing the relationship between Brazil and south-Southeast-Midwest - Region is utilized in order to establish the GDP corresponding only for these regions. On the next items these procedures are explained step by step.

-90-

b) Basic data for demand forecast and the relationship with Brazil and South-Southeast-Midwest Region:

The basic data available for forecast are indicated in Table III-1.4, and they are published by "Fyndacao Getulio Vargas" and "Fundacao Instituto Brasileiro de Geografia e Estatistica", the main organizations in Brazil, which deals this kind of data. For the population of Brazil, there are only the results of Census which is provided once a decade.

Grompertz's equation is utilized to determine the intermediate values.

Figure III-1.2 indicates the correlation between GDP and the consumed energy in Brazil, showing 2 trends with one tendency before 1974 and another after 1974. For the purpose of this study it is considered that the equation established for the period 1974-1981 will remain until 2000, and by means of this equation, the energy required is forecast considering the evolution of the national economy as indicated in next step.

However, the use of this method to forecast the necessary energy in S/SE/MW Region has one trouble that there is no data about the GDP in this region. As the importance of this region on the economy of Brazil is high, it is assumed that there are relationships between consumed energies, and in fact, Figure III-1.3 indicates a good correlation that can be used to estimate the gross product equivalent to the S/SE/MW Region.

So, the GDP for this region is estimated by means of yearly relationship with the generated energy between Brazil and S/SE/MW Region, and the Table III-1.5 indicates the results of this procedure.

For the population forecast, Gompertz's equation is adopted as adopted for the Brazil case.

The correlation between equivalent GDP for S/SE/MW Region and its consumed energy is indicated in Figure III-1.4 and equation considering the period 1974 - 1981 is utilized to establish the energy requirements until 2000 according to the evolution of the economy of this Region, as indicated in next step.

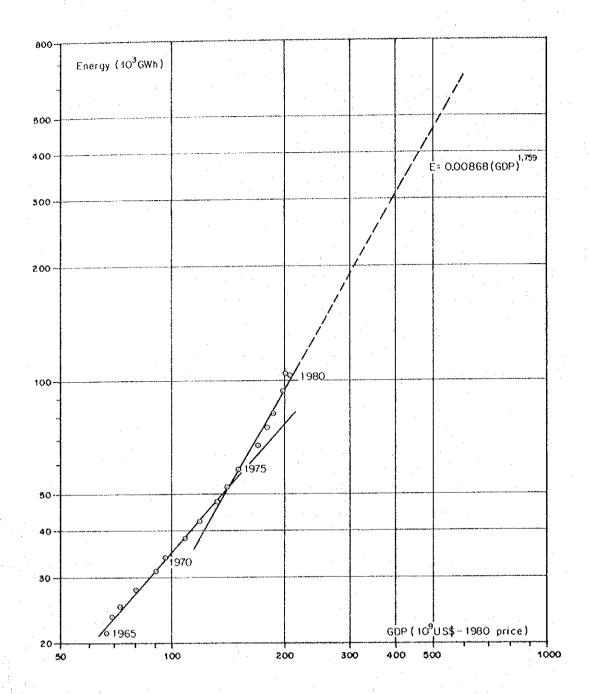

FIGURE III-1.4 CORRELATION BETWEEN GDP AND ENERGY FOR S/SE/MW REGION OF BRAZIL

c) Annual growth rate of GDP and consumed energy, and results of demand forecast by Macro-Method:

The annual growth rate of GDP and consumed energy is indicated in Figure III-1.5 for Brazil and Figure III-1.6 for its S/SE/MW region. A general trend of GDP considering triannual movable average rate is also indicated in these figures and the equations are developed.

-94-

So, for the prediction of annual growth rate of GDP, assumptions are made in order to follow the general trend according these equations as indicated in Figures III-1.5 and III-1.6, and in Tables III-1.6 and III-1.7. These tables also present the results of the demand forecast for Brazil and its S/SE/MW Region.

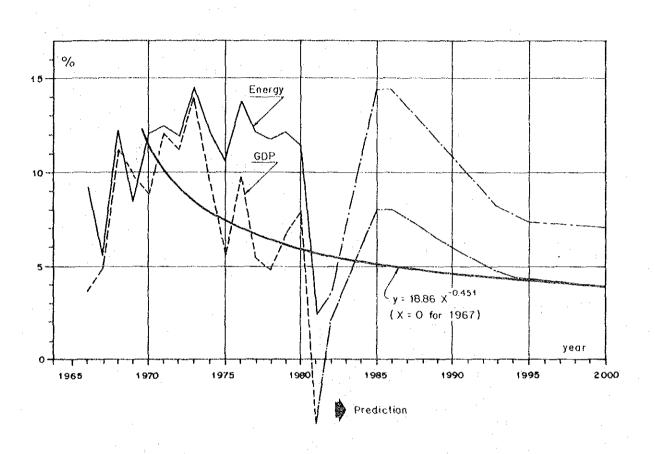

FIGURE III-1.5 ANNUAL GROWTH RATE OF GDP AND CONSUMED ENERGY IN BRAZIL

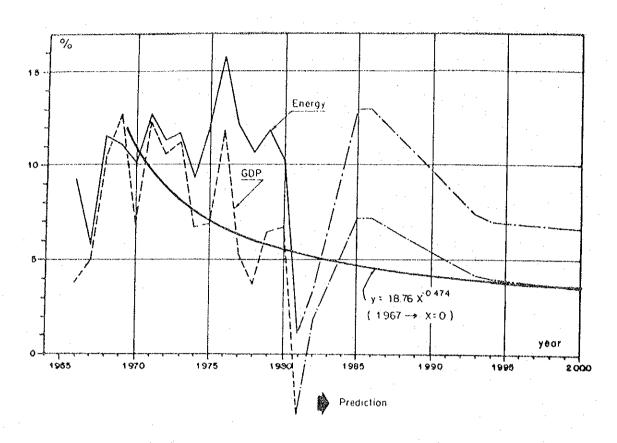

FIGURE III-1.6 ANNUAL GROWTH RATE OF GDP AND CONSUMED ENERGY IN S/SE/MW REGION OF BRAZIL

Obs: For the S/SE/MW Region, the values of GDP are calculated by means of correlation shown in Figure III-1.2.

d) Results of the study:

A comparison of the results of forecasts are given in Table III-1.8 and Figure III-1.7.

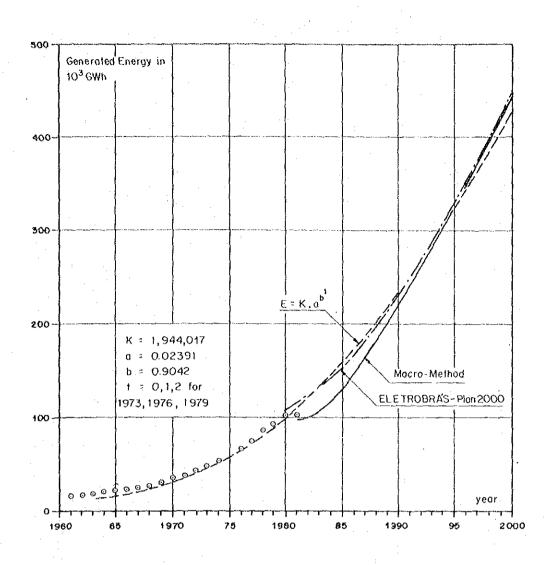

FIGURE 111-1.7 COMPARISON OF ENERGY DEMAND FORECASTS FOR S/SE/MW REGION OF BRAZIL

	and the second							
					and the second	and the second		
TABLE III-1.8.	COMPARISON C	OF	ENERGY	DEMAND	FORECASTS	FOR	S/SE/M₩	REGION

Year	Plan 2000 Electrobras(a)	Gompertz's equation(b)	Macro-Method (c)	$\frac{(a) - (c)}{(c)} %$	$\frac{(b) - (c)}{(c)} %$
1985	154.3	160.5	130.3	18.4	23.2
1990	237.6	235.7	223.0	6.5	5.7
1995	334.0	326.5	324.2	3.0	0.7
2000	454.1	430.0	445.9	1.8	-0.5

(unit:  $10^3$  GWh)

As it is clear in the Table and Figure, the annual gross energy by the Macro-Method is usually lower than the other results and for the period 1981-1990, the difference in percentage is high. This is because Macro-Method considers the negative value of GDP in 1981 and after then, the trend is gradually recovered meanwhile the other methods do not take into account of this typical year. However for the period 1990-2000, those forecast methods do not show much difference and this period is most important for this study so that they are judged to be quite same in regard to the growth rates.

Therefore, the results estimated by Macro-Method are adopted as the demand forecast. The load factor is forecast to be 63.5% from the past performances and a reserve factor of 15% is considered as the maximum demand considering the factor utilized by ELETROBRAS in its plan.

Accordingly, the results of demand forecast can be summarize as follows;

Year	Gross ener	gy required	Power	Maximum demand
reat	GWh	MW year	MW	MW
1981	95,810	10,930	17,210	19,795
82	98,860	11,280	17,760	20,430

TABLE III-1.9. RESULTS OF DEMAND FORECAST FOR S/SE/MW REGION OF BRAZIL

-100 -

#### Demand and Supply Balance 1.2.

#### Planning for supply 1.2.1.

The total potential of hydroelectric power resources in Brazil is said to be 106,500 MW year of which 49,800 MW year is in S/SE/MW Region, as indicated in Figure III-1.8 and Table III-The annual totals of the hydraulic energies available in 1.10. S/SE/MW Region are indicates in Table III-1.11.

(*) Including 9 nuclear power stations.

The electric power development plans from 1982 to 2000, according to the PLAN 2000 - ELECTROBRAS, are indicated in Tables III-1.12 and III-1.13. However, after 1996 this PLAN is not complete about the construction schedule of power stations, and the result is that there are more than 7,000 MW year deficiency in the firm energy and 13,500 MW deficiency in the maximum demand up to the year 2000. However, the PLAN 2000 - ELECTROBRAS mentions that, during the period from 1996 to 2000, the energy requirements of the S/SE/MW Region may be supplied of 3150 MW year from the North Region specially from the Tocantis/Araguaia and Xingu River Basins, through electric interconnections between these basins and the main load centers of the Southeast Region. ELECTROBRAS considers that the hydroelectric potentials of the Southeast and South Regions, which are sufficient to supply the market of these Regions, shall have their uses from 1997 to 2000 by means of a more accurated economic comparison with the supply from the North Region of Brazil.

Anyway, for the purpose of this study, it is enough to consider simply that new additional power stations have to be completed during 1996-2000, besides those mentioned in the PLAN 2000. These new power stations shall be either the thermal power stations or the hydroelectric power stations at a long distance, something like more than 1000 km (North Region) and, in this case, they are considered as a base load power stations with about 70% of load factor. This assumption, even for the hydroelectric power stations, is quite reasonable because of too costly transmission lines for long distances.

-102 -

The construction and production schedules of these new additional power stations are indicated in Table III-1.14. They are simply computed in this table, only to satisfy the energy dificiency during the period 1996-2000, and it is considered that the detailed planning of these new additional power stations is out of the present study.

However, it is enough to observe that, even taking into account of the addition of the new power stations, the installed capacity will not be sufficient for the maximum demand. Accordingly, São Lourenço (2835 MW) and Cubatão (2400 MW) Reversible Power Stations are planned especially for the peak-load supply during period 1996-2000.

Therefore, according to the present plan, the total installed capacity in 2000 is to be expanded 3.5 times of the present with total output 96,500 MW. The plan also calls for the annual firm energy to be increased to 460,500 GWh with 3.8 times of the present. With regard to expansion of hydroelectric facilities, it is planned to be an installed capacity of 79,200 MW in 2000, approximately 3 times of the present considering that the new power stations after 1996 are hydroelectric power stations. As a result, up to 2000, hydroelec power stations will represent 80% of total installed capacity of S/SE/MW Region as indicated in Figure III-1.9 although at present it represents 90%, and this is because of gradual introduction of nuclear and coal thermal power plants. The major hydroelectric power stations presently being constructed are listed in Table III-1.15.

Obs.: This table considers the informations available in PLAN 2000-ELECTROBRAS. Values of firm energy for each hydroelectric power stations take into account of the most driest period 1952-56, and these data are available in Plan 90, Plan 92 and Plan 95 of ELECTROBRAS, and in the reports of other companies. For the period 1995-2000, see also Table 111-1.14.

98	42,408	3,800	46,208	76,753	5,430	2,190	84,373
99	43,505	5,400	48,905	78,333	7,715	4,035	90,083
2000	43,730	8,800	52,530	78,668	12,570	5,235	96,473

Obs.: New power stations are indicated only to complete the energly deficiency in the Plan 2000, during the period 1996-2000, because there is no definite planning for this period. They are considered to be thermal or long distance hydroelectric power stations, both in the base load operation.

- Cubatao III and São Lourenço Power Stations are reversbile power stations so that the energy in MW year is neglected.

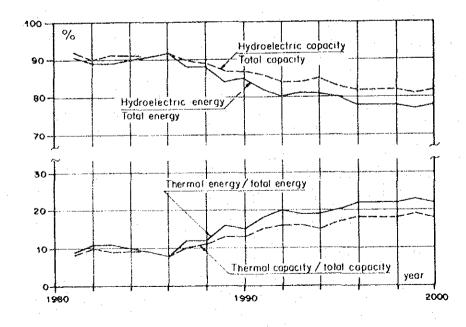

FIGURE III-1.9 RATIO OF HYDRAULIC AND THERMAL POWER STATIONS IN TOTAL INSTALLED CAPACITY (S/SE/MW REGION BRAZIL)

Taquaruçu	500	213	1987 - 1988

#### 1.2.2. Demand and Supply Balance

From the forecast results according to the Macro-Method, and the supply plan described in 1.2.1 the balance sheet predicted for electric energy and maximum demand up to 2000 is indicated in Tables III-1.16 and III-1.17. The general trends of demand and supply balance are graphically indicated in Figure III-1.10.

As it is clearly seen in the Table III-1.17 and in the Figure III-1.10 according to the ELETROBRAS - PLAN 2000, there are surplus energy and installed capacity up to 1995, and probably some of power stations may have a little more later year of commissioning. However, after 1995, new power stations will be necessary in order to supply the energy for the S/SE/MW Region, and besides that, other power stations will be required especially to supply the maximum demand.

### TABLE ITI-1.17. ESTIMATED MAXIMUM DEMAND BALANCE

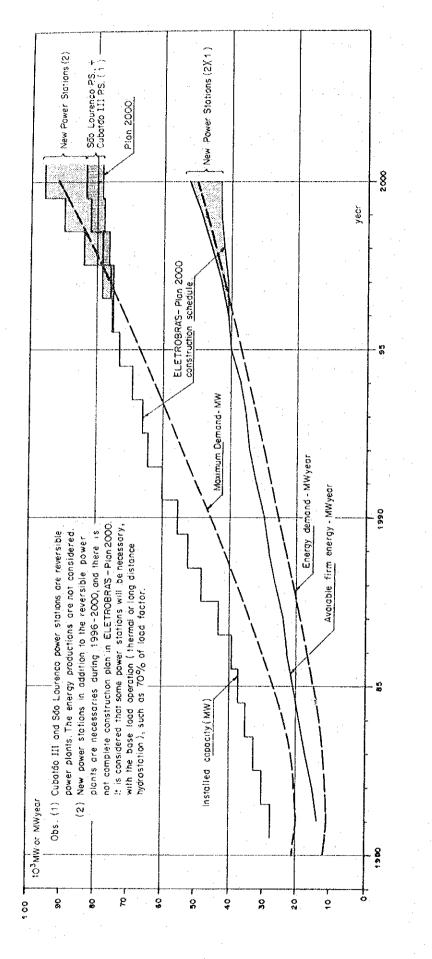

FIGURE III-1.10 DEMAND FORECAST FOR SOUTH-SOUTHEAST-MIDWEST REGIONS OF BRAZIL-ENERGY AND POWER

-110 -

For this purpose, DAEE forecasts the year of commissioning of São Lourenço and Cubatão Reversible Power Stations during the period 1996-2000, according to the Table III-1.18. It is judged appropriate to start these projects at that time, considering not only for energy balance but also the water supply and demand balance for the energy balance but also the water supply and demand balance for the São Paulo Metropolitan Region, which will also require the operation of the São Lourenço Reversible Station in 1996 as shown in the Chapter 2 - Part III.

In addition, it is necessary to mention that the new power stations required after 1996 will probably be hydroelectric power stations from North Region more than 1,000 km from the Southeast load center. In this case, it is supposed that those power stations have to operate in the base-load generation, because the transmission line costs and loss costs are supposed to be very high, and in this case the reversible power stations close to the load center, will be probably much more advantageous. In the case of São Lourenço Power Station, its convenience is also closely related to the necessity to supply clean water to São Paulo Metropolitan Region.

Also, the Cubatão III Power Station is planned for this period with year of commissioning in 1998, because of the gradual availability of the water supplied to Sao Paulo, which will return to the existing - ELETROPAULO Hydroelectric Power System in the Tiete-Pinheiros and Billings System.

The construction schedule of São Lourenço and Cubatão Reversible Power Stations are indicated Table III-1.18.

Finally it is important to mention that, although electric power side is indicated that São Lourenço Power Station has to Start operation in 1996, it is necessary to consider the existing restraints about some water supply systems, as presented in Part III-Chapter 2.

-111-

Year	São Lourenço Power Station			Cubatão III Power Station		
	Units	MW	Total MW	Units	MW	Total MW
1996	1	315	315	-	-	
1997	2	630	945	; <u> </u>	-	
1998	3	945	1,890	1	300	300
1999	3	945	2,835	3	900	1,200
2000	-	-	_	4	200	2,400

#### TABLE III-1.18. CONSTRUCTION SCHEDULE OF SÃO LOURENÇO AND CUBATÃO III REVERSIBLE POWER STATIONS

Obs.: The operation year takes into account of only the energy balance. Considering the water supply balance, the operation year of São Lourenço Power Station has probability to have to be situated during 1992 - 1996.

Considering, for example, that Alto Tiete and Cantareira Systems have to release  $12 \text{ m}^3/\text{s}$  of water for the downstream users, the sewage dillution and the irrigation, the conclusion is that São Lourenço Reversible Power Station has to start the operation by 1996, at least with one unit. Especially for the São Lourenço Power Station, the operation years have to be analysed closely to the water supply side schedule.

#### CHAPTER 2. DEMAND AND SUPPLY FORECAST OF WATER

#### 2.1. Demand Forecast

According to the existing water supply plans, already presented in the Chapter 3 of Part II, "HIBRACE PLAN" and "SABESP PLAN" for water supply have to provide enough water until the year of 2000. The population forecast and water demand in the Metropolitan Region of São Paulo according to existing studies are presented in the Figures III-2.1 and III-2.2.

For the present report, the water demand forecast for the Metropolitan Region of São Paulo, is made by means of more recent data of population (results of 1980 Census) and is provided up to the year of 2040. The considerations about the water demand forecast are presented in the next items.

#### 2.1.1. Forecast of Population

The forecast of urban population of Metropolitan Region of São Paulo is based on the Compertz equation as follows:

where:

 $p = k a^{b}$  p = population in the time t k = maximum population

a and b = coefficients.

In applying the decimal log for the above function and using the results of last census (1960, 1970 and 1980), the values of coefficients k, a and b are determined and the results are:

> k = 45, 462, 600a = 0.999

The evolution of the total population of Metropolitan Region of São Paulo for the same period is estimated by means of the urbanization rate using the same estimation method.

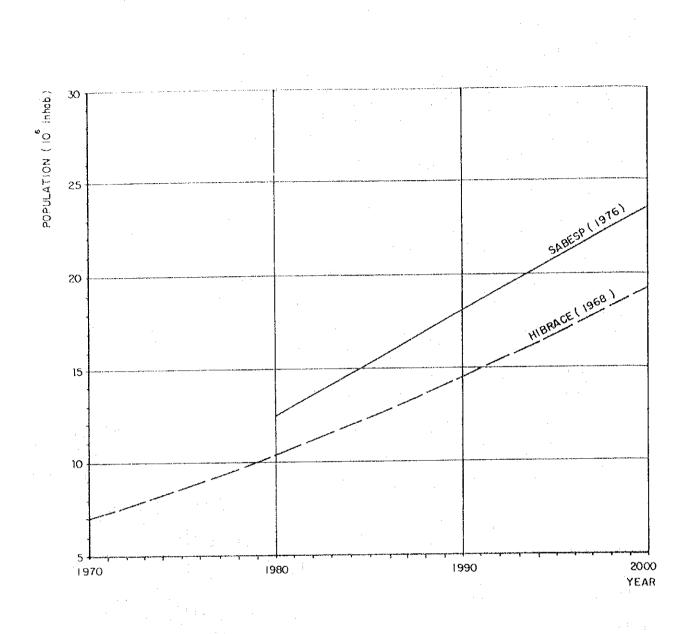

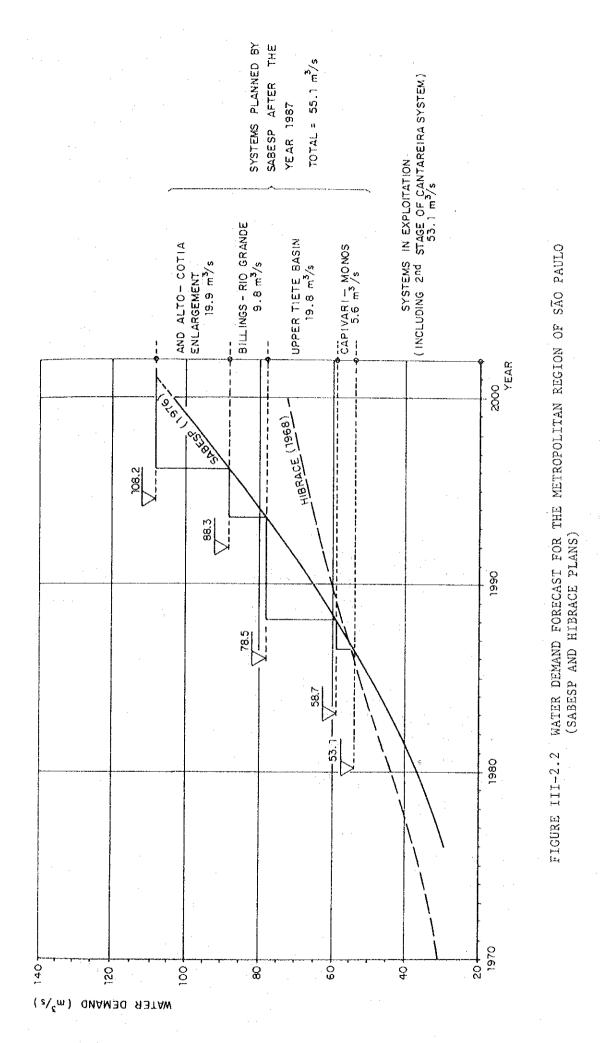

FIGURE III-2.1 FORECAST OF THE POPULATION FOR THE METROPOLITAN REGION OF SÃO PAULO (SABESP AND HIBRACE PLANS)

-118-

-- 119 --

The Table III-2.1 is presented summary of estimated results including results obtained in census until 1980. The Figure III-2.3 is presented evolution curve of population in the Metropolitan Region São Paulo.

(*) Results of Census

#### 2.1.2. Water Demand Forecast

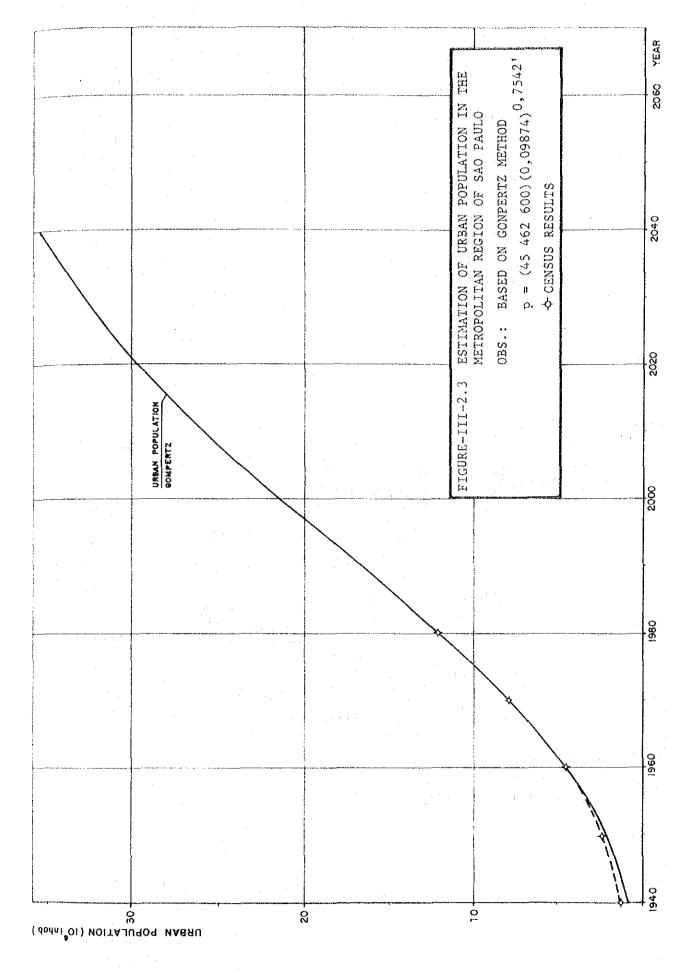

The estimation of water demand for the Metropolitan Region of São Paulo is made considering that the present (1980) average "per capita" consumption of 282 l/inhab. day in the year of 2040, as observed in the main developed cities of the world.

The Figure III-2.4 is presented the curve of evolution of the prospected average "per capita" consumption assumed in this study.

As regard to the rate of water supply population, it is assumed that as verified to be 90% in the decade 80, the rate will increase to 92% in the decade 90, and from year 2000 to year 2040, the rate will be stable in 95%.

The Table III-2.2 shows the result of the water demand forecast, and the Figure III-2.5 indicates the evolution of water demand until the year of 2040.

-121 -

Year	Urban Popula tion (inhab)	Rate of Supplied Population (%)	q (1/inhab./day)	Q (m ³ /s)
1980	12,183,139	90	282	36
1990	16,840,500	92	334	60
2000	21,497,400	95	377	89
2010	25,843,400	95	408	116
2020	29,693,100	95	430	140
2030	32,971,000	95	444	161
2040	35,681,000	95	450	1.77
