The size of the premium on peanut oil as compared with other vegetable oils changes with fluctuations in the price of peanut oil and/or in the prices of other oils. That is, the higher the premium on peanut oil becomes relative to other oils, the less will be the demand for peanut oil, as a result of substitution of other oils. Inversely, the lower the former, the higher the latter.

According to the price correlation coefficient between edible vegetable oils as quoted in the part of General Description on Oilseeds and Oils, oils with a strong correlation to peanut oil are soybean oil and rapeseed oil. In terms of uses, these two oils can generally be substituted for peanut oil as materials for shortening and margarine. Though peanut oil possibly maintains a strong position as a salad oil owing to its unique flavor, other high-quality oils, e.g., sunflower and cottonseed oils, may take the place of peanut oil in this area of use.

III. Concluding Remarks

Though the previously mentioned strong correlations between peanut oil and other oils make it difficult to project the future demand for peanut oil alone, the following projection may be made based on the characteristics of peanut oil:

In India and China, which are two major producing countries, it is projected that production will continue to gradually increase, but little surplus for export will occur because the surplus of production will be absorbed into domestic consumption, which per capita remains low compared with developed countries. It may also be considered that the production of peanut may decrease as a result of the fall in its domestic market price, if low-cost palm oil is imported as a substitute for peanut oil as a material for vanaspati (an indispensable food in India), as already mentioned, or if such policies as importing cheap palm oil and exporting the more expensive peanut oil are adopted. In the latter case, however, the problem is the competitive power of Indian peanut oil in the international market.

As shown in Appendix Table 5, Brazil, Argentina and Senegal have a large share in the export of peanut oil and high export ratios, though production is low. Argentina in particular exports nearly all the oil produced. These countries are all developing countries and may increase their oil consumption as a result of future economic development and increases in national income, but in Argentina and Senegal, it does not seem that the increase in domestic oil consumption will cause exports to sharply decrease because these countries are sparsely populated. In Southeast Asian countries, as represented by Burma and Indonesia, peanut is widely cultivated as a food. Both Burma and Indonesia produce more peanut than Brazil or Argentina. If these countries increase their production, they may emerge as exporters of nuts or oil. In recent years, these countries have attached importance to peanut as a crop for agricultural development, especially as second crop after paddy and in the development of farm industries (e.g., oil extraction).

On the other hand, from the point of view of importing countries, the West European countries are overwhelmingly important markets, as previously stated. Peanut oil, the so-called premium oil, is the highest-quality edible oil, and maintains that premium position, especially as a salad oil. In applications such as for shortening and margarine, however, since other vegetable oils may easily substitute for peanut oil, peanut oil consumption will fall if the premium on peanut oil is too high.

[1-2-4-2] SUNFLOWER

A. SUNFLOWER SEED PRODUCTION, EXPORTS AND IMPORTS

I. Production

The cultivation of sunflower is classified by use into two groups: ornamental flower cultivation and seed-collection cultivation. The former is economically negligible, while the latter has two applications: for oil extraction and for food. The sunflower seed used for the former application is the small-sized seed containing 42-50% oil, while the latter application uses the large-sized seed containing 25-35% oil. The vast majority of the sunflower cultivated throughout the world is used for oil extraction.

Sunflower can be cultivated in both the tropical and temperate zones because it is highly adaptable to natural conditions. While regular rain throughout the growing period is important, sunflower also has the ability to resist dryness by drawing water from under the ground with its extensive root system.

The harvesting period for sunflower seed is generally from September to October in the northern hemisphere and from March to July in the southern hemisphere (in Italy and Spain, from July to August).

Statistics for area under cultivation and production of sunflower seed by country (FAO, <u>Production Yearbook</u>) are shown in Appendix Table 1. According to this Table, sunflower seed is produced in about fifty countries; the USSR accounts for about one third of the total world production, followed by the United States with 17%, then by Argentina and China. These four major producing countries account for about 65% of the total world production. Since in Romania, Hungary and Bulgaria the production is also high, the East European bloc accounts for nearly half of world production.

From the point of view of trends in production in the 1970s, the total world production rose by 39% from 9.82 million tons (the annual average over the period 1969-1971) to 13.76 million tons in 1981, whereas the output in the largest producing country, the USSR, dropped from 6 million tons to 4.6 million tons. On the other hand, the

Table A-1 Harvesting Time for Sunflower Seed in Main Producing Countries

Source: Oil World

output in the United States increased by 17 times, from 120,000 to 2.1 million tons.

Trends in sunflower seed production since 1966 are shown in Appendix Tables 2 and 3 on the bases of area under cultivation and production for the main producing countries, respectively. According to these Tables, a large increase in the United States occurred in the second half of the 1970s, while the production in the USSR has continued to decline with some fluctuation since 1966.

In the USSR, both area under cultivation and yield have fallen, whereas in the United States, both have risen.

Though production in China has shown a remarkable increase since the middle of the 1970s, it is still far less than that of the USSR or the United States.

II. Exports and Imports

Sunflower seed production is used partly for subsequent sowing,

as a food, and as feed for small birds, 1) but mostly for crushing. The seed is mostly crushed in the producing countries, but is also exported as material for crushing. Amount and value of export of sunflower seed are shown in the Appendix Table 4.

As shown in this Table, the average total world exports over the last three years (1978 to 1980) were 1.79 million tons. Compared with the average total output in the same period, as shown in Appendix Table 3, about 13% of production was exported.²) This figure, however, represents the ratio of exports to the total world production, and the proportion is very different in various countries. For example, aside from the USSR, of the main producing countries, China and Romania export none or almost none of their production, whereas the United States exports about 57% of its production, accounting for 77% of the total world exports (All calculations are based on the average over the above three-year period) (Appendix Table 4).

According to Appendix Table 5, which shows imports and corresponding exports, the main importing countries are concentrated in Europe, with the Federal Republic of Germany the largest importer, and Mexico the only main importing country outside Europe. In this regard, almost all of the imports of sunflower seed and oil by Mexico are based on a governmental agreement with the United States (see Table 11 in the first part of this chapter, General Description on Oilseeds and Oils). It is a feature of sunflower seed as an international commodity that the United States (in exports) and Europe (in imports) account for the majority of the trade.

B. SUNFLOWER OIL PRODUCTION, EXPORTS AND IMPORTS

Sunflower oil extraction is carried out in almost the same manner as for other oilseeds (see General Description on Oilseeds and Oils 4.2). Accordingly, mills which crush soybean and cottonseed perform

2) Though there is a time lag between production and export, it is assumed that there is no substantial discrepancies: mean production and exports over this three-year period are used here.

¹⁾ The meal left after oil extraction is used as a feedstuff, whereas the raw seeds are used as feed for small birds and pets.

sunflower oil extraction as well, but in sunflower producing areas in the United States, there are some oil mills exclusively for sunflower.

The husks covering the sunflower seeds are usually removed before crushing. Some mills crush seed in the husk in order to save time, in which case the oil is poor in quality. The meal produced in this manner contains much fiber, which is good for ruminants but too fibrous for other animals' feed.

Sunflower oil is used as a frying oil, a salad oil and as a material for shortening and margarine, and it has a unique flavor (Low linoleic acid is said to account for the good flavor). In the United States it is also used widely as a frying oil for potato chips.

Since sunflower oil contains abundant linolic acid (a polyunsaturated fatty acid) and α -tocopherol (Vitamin E, which has beneficial physiological effects), it is popular as a health food.

As previously stated, the majority of sunflower oil is extracted in sunflower seed producing countries. Among the countries which import seeds for crushing, the Federal Republic of Germany has the largest production. South European countries such as France, Spain and Portugal also crush seeds, both domestic and imported.

Sunflower oil production by country is listed in Appendix Table 6,1 and the production and exports by the main producing countries in 1981/82 are shown in Table B-1 below.

As shown in the Table, the total world production of sunflower oil is about 5 million tons and the total exports are about 1.12 million tons; thus a large proportion of sunflower oil is consumed in the producing countries. It may be said that the USSR and China, which are the major producing countries, consume all the oil they produce, although the USSR exports a small amount of its oil, and imports more than that, as described later. On the other hand, Argentina, the United States and the Federal Republic of Germany export half of their production or more, and especially in the United States the export ratio is high.

Imports corresponding to the exports mentioned above are shown in Appendix Table 6, and the imports by main importing countries in recent

1) Appendix Table 6 is derived from the U.S. Department of Agriculture (USDA), Foreign Agriculture Service (FOP 6-8, May 1982). Statistics for area under cultivation and production of sunflower seed shown in this Table are different from those of FAO's Production Yearbook in Appendix Table 1 with regard to time period (FAO uses calendar years while USDA uses harvesting years), but mostly agree with each other. Since FAO statistics are not available on oil and meal production, USDA statistics are mainly used for the supply and demand analyses in this chapter.

years are shown in Table B-2 below. The USSR has been the largest importing country since 1979, before which it was one of the main exporting countries (and largest exporting country in the 1976/1977 period). This reversal was caused by the decrease in production of sunflower seeds.

C. SUNFLOWER OIL CONSUMPTION AND PRICE

I. Consumption

Sunflower oil consumption by country, as estimated from the oil output, export and import figures, is shown in Appendix Table 6, and consumption in the main consuming countries in recent years (1981/ 1982) is shown in comparison with production, in the following Table:

			$A_{ij} = A_{ij} = A_{ij}$
		(1,000 tons)

Germany, FR	0	226	125

Table C-1 Sunflower Seed Production, Oil Production and Consumption in Main Countries

Source: Excerpted from Appendix Table 6

The above Table shows clearly that the greatest portion of sunflower oil consumption is supplied by domestic production, and any deficiency or surplus, i.e., the difference between production and consumption, results in exports or imports.

Consumption by country, as shown in the Table, however, does not represent the level of consumption in each country. Consumption per capita, which is calculated by dividing consumption by population, is an average of approximately 1.1 kg annually in world consumption, but differs sharply by countries.

Bulgaria has the highest per capita consumption (15 kg), followed by Romania with 9 kg. On the other hand, the main countries with the lowest consumption are the United States with 0.2 kg and China with 0.24 kg. In the USSR and other East European countries, the per capita consumption is generally high.

II. Price

As already mentioned, sunflower seed and oil are consumed mainly within the producing country, and are distributed as international commodities in small quantities; the largest supplying country of both seeds and oil in the world market is the United States. Since production in the United States is concentrated in the northwest, Minneapolis, the capital of Minnesota State, is the market center, and spot and futures transactions in sunflower seed are conducted in the Minneapolis Grain Exchange. The price in Duluth, Minnesota, becomes the standard export price and the standards set up by the Minnesota State Department of Agriculture become the international standards, since almost all of the export volume is shipped from that port.

As previously stated in General Description on Oilseeds and Oils, there are strong correlations between the prices of various oilseeds and those of oils; since sunflower oil has a strong correlation to soybean oil, rapeseed oil, cottonseed oil and peanut oil, their prices over the past decade are listed together in Table C-2 below.

As shown in the Table, the price of sunflower oil is lower than those of peanut and cottonseed oils, and higher than those of soybean and rapeseed oils.

Recent annual average prices and monthly prices are shown in Tables C-3 and C-4 and in Fig. C-1 in relation to soybean and rapeseed oils, which lead the world market prices for vegetable oils and have the strongest influence on the price of sunflower oil.

The graph shows that the price of sunflower oil moves with the prices of soybean and rapeseed oils, but that its rise in the 1978/ 1979 period was greater than that of soybean and rapeseed oil prices. In this period, the prices of oils rose on the whole, and the USSR reduced sunflower oil exports by about 100,000 tons and began to import it for the first time, which may have raised the price of sunflower oil higher than that of other oils. In the reactionary price fall in the following 1979/1980 period, the price of sunflower oil fell more sharply than other oils, because the United States Table C-2 Annual Average Prices of Main Vegetable Oils

increased production in response to the high price in the preceding year.

Though sunflower oil is always more expensive than soybean and rapeseed oils, sunflower meal is the cheapest of these three kinds of meal. There are price correlations between these three kinds of meal, but no price correlation is found between sunflower oil and sunflower meal (In the case of soybean, the price of the meal has an effect on that of the oil. See the preceding part of this chapter on soybeans).

D. SITUATION IN MAIN PRODUCING COUNTRIES

I. USSR

As already mentioned, the USSR ranks first in world sunflower production, accounting for about 32% of the total world production (1981/1982), although its production has declined since the 1970s.

Sunflower seed production in the USSR declined from an annual level of about 6 million tons in the 1960s to 5 million tons in the 1970s (but exceeded 6 million tons in the good harvest period of 1973/ 1974), and to 4 million tons in the 1980s. These decreases paralleled decreases in area under cultivation and in yield.

The yield, as shown in Appendix Table 1, fell from 1.29 tons/ha on the average in the 1969-1971 period to 1.08 tons/ha in 1980. A comparison of the yield in the USSR with the yield in other main countries is shown below:

	USA	USSR	Argentina	China
1969/71	1.10	1.29	0.74	0.87
1981	1.32	1.08	0,98	1.61

 \bar{U}_{2}

This table shows that only the USSR had a decrease in yield, whereas other main producing countries registered increases. The low crop yield is said to be attributable to the varieties. Unlike the United States (referred to below in Subsection II) where the use of hybrid-seed raised the yield, the USSR is still using ordinary varieties.

Recent the USSR's production, exports and imports of main oilseeds and oils are shown in Table D-1 below. It can be seen that despite the decrease in production mentioned above, sunflower still remains an important source of oil, accounting for about one third of the total oil output (including animal oil) in the USSR.

As a result of the decrease in the production of sunflower seed, which is the most important oil material, oil supply and demand in the USSR has become more stringent in recent years, and imports of soybean for use as a material, and of soybean oil, palm oil, sunflower oil, coconut oil, butter and so on have been increasing.

Ø

As for sunflower oil, the USSR was the largest exporting country in the world until the middle of the 1970s, but has become one of the main importing countries in recent years (with much higher imports than exports).

This has created a serious problem in the livestock industry in the USSR, in that the decrease in sunflower production resulted in a shortage of oil and a shortage of oil meal for use as a protein feed.

Though the numbers of the major livestock in the USSR (i.e., beef cattle, dairy cattle, pigs, sheep and goats) has continued to increase steadily, the production of such livestock products as beef, milk and pork has generally fallen since 1978. This may mean that feed supplies have been unfavorable and have resulted in a decrease in production, since poor-quality feed can only maintain the current number of cattle.

In these circumstances, the Government of the USSR is urgently trying to increase the production of soybean and sunflower as oil crops and for feed under a production plan as follows:

Table D-2 Production Plan of Soybean and Sunflower, USSR

		(1	,000 tons)
· · · · · · · · · · · · · · · · · · ·	1976/80	1981/85	1986/90
	average result	plan	plan
Soybean Sunflower	500 5,300	1,400 6,700	2,200-2,300 7,200-7,500

Source: Oil World

In this plan, it seems that the target production level for soybean is much higher than the present level, but that for sunflower is not much higher.

II. The United States

It was mentioned earlier that the United States is second to the USSR in sunflower seed production, and stands first in world sunflower seed and oil exports. Production and exports of sunflower seed and oil by the United States in the last six years are shown in Appendix Table 7, and it can be noted that the production jumped to nearly double, from 1.8 million tons in 1979 to 3.48 million tons in 1980. In the following year, production returned to 1.8 million tons as the result of an increase in stock (owing to the large increase in production in the previous year and to a fall in price), but the normalization of stock is resulting in a further increase. This phenomenon implies that U.S. sunflower producers are strongly responsive to price changes, and there is a strong possibility of production increases, determined by price (i.e., position relative to other crops).

The United States' sunflower production is concentrated in three northwestern states: North Dakota, South Dakota and Minnesota, which together account for 98% of national production. In particular, North Dakota accounts for 59% of the national production (1980).¹

Certain features have made North Dakota the most prominent state in American sunflower production: the low annual rainfall (360 to 510 mm) in this state is tolerable to sunflowers with strong drought resistance; and labor and machines can be effectively used since wheat and barley, which are crops also with drought resistance, are harvested in August, while sunflowers are harvested in September and October.

In North Dakota, sunflowers are generally cultivated in rotation with wheat and barley instead of in consecutive sunflower cultivation, because sunflowers absorb more water and nutrients from the soil than other crops.

The dissemination of hybrid seeds is considered to have brought about a higher yield of sunflower in the latter part of the 1970s in the United States. There are about twenty companies producing hybrid seeds, some of which produce seeds not only for local use but also for California State, Florida State and Argentina. Hybrid seeds contribute to increases not only in seed production but also in oil production, since they provide a high rate of oil extraction.

Of all the sunflower seed produced in the United States, about 63% is exported and the rest is crushed within the country. About 56% of the oil extracted is exported and the rest goes for domestic consumption.²) All meal produced along with the oil goes for domestic use.

Thus, though the United States is the major sunflower producing country, sunflower oil has a low rate of domestic use because more than half of the products (seeds and oil) are exported. In the consumption of vegetable oil in the United States, soybean oil occupies

1)	USDA,	Agriculture Statistics, 1981	
2)	Since	the export ratio fluctuates yearly, these figures were	esti-
	mated	from the most recent three-year average.	

the largest share in general, despite yearly changes, followed by palm oil (imported), cottonseed oil, coconut oil (imported) and corn oil, and the share of sunflower oil is almost negligible. Accordingly, sunflower oil consumption per capita in the United States is quite low compared with that in other sunflower producing countries.

III. Other Major Producing Countries

Producing countries which follow the USSR and the United States are Argentina and China, both of which have shown growth in recent years (see Appendix Tables 2 and 3).

Argentina exports part of the seed produced (with large yearly changes), whereas China crushes all its seeds domestically.

China consumes all of the oil it produces within the country, whereas Argentina exports almost half of its oil, being the largest exporting country in the world, as already mentioned (see Apendix Table 4), and also the major sunflower seed meal exporting country.

In contrast to the above-mentioned major producing countries, the Federal Republic of Germany is typical of importing countries. That is, the Federal Republic of Germany annually imports about 700,000 tons of sunflower seed to produce about 260,000 tons of sunflower oil. About 155,000 tons of the oil produced is exported, mainly to neighboring countries; and there are some imports of oil (all figures refer to the most recent three-year average).

E. CONCLUDING REMARKS

As shown above, the production and consumption of sunflower seed and oil in the world have slowly increased in a parallel manner in recent years. These increases in the world and in each main country are shown in Appendix Table 7.1)

In the production of sunflower seed and oil, the USSR and the United States hold a very large share, and future world supply and demand may largely depend on trends in these two countries and in Argentina, where production has recently grown.

As for production in the USSR, oil supply and demand problems will be eased if the previously mentioned government planning, especially for a large increase in soybean production, is carried out. In such a case, the imports of soybeans and sunflower would decrease, but not to such an extent as to provide a surplus for sunflower oil exports.

As already mentioned, since U.S. sunflower production fluctuates according to price, there is large potential for an increase in sunflower production, but such potential largely depends on the price relative to that of other competitive crops (wheat and barley) in main producing countries.

From the point of view of demand, sunflower oil has a strong substitutive relationship with soybean oil and rapeseed oil. There is a possibility of a shift in demand from low-priced oils to sunflower oil as a result of an increase in income, unless the premium on sunflower oil becomes larger because of its flavor or as a result of increased propensity to consume polyunsaturated fatty acids in consumers who are sensitive to cholesterol. Thus, it may be considered that sunflower oil supply and demand will continue to increase slowly in parallel.

 Appendix Table 7 is based mainly on USDA-FAS statistics in Appendix Table 6, complemented by figures in Oil World. Since FAO statistics (Appendix Table 1) carry figures for oilseed production but not for oil production, USDA data were also used for production figures in order to compare seed and oil production (Appendix Table 7).

[1-2-4-3] COTTONSEED

A. INTRODUCTION

Cottonseed is a byproduct of cotton production. In other words, the cotton plant provides staple cotton as the primary product, and linter and cottonseed as byproducts, the latter providing cottonseed oil and meal.

Linters are the short fibers attached to the seeds left after the removal of staple cotton; the short fiber linters of the first cut are used as materials for mats and coarse yarns, and cellulose, which is the principal chemical component of the linters of the second and subsequent cuts, is used for various kinds of chemicals (e.g., acetate rayon, plastics and gunpowder).

Crude oil is obtained from the seed after linter removal by means of crushing or by solvent extraction. In the former case, 3.5 to 7% of the oil remains in the meal, and in the latter case, the oil content of the meal is 1% or less.

Cottonseed oil is used almost exclusively for food, and only the sub-standard goods and soap-stock produced during refining are used in the non-food industries.

Cottonseed oil is used mainly as cooking oil and salad oil in the home and in restaurants, and also as a material for processed oil products such as margarine, shortening and mayonnaise (mentioned later).

The meal obtained after cottonseed oil extraction is used as protein feed.

Although cotton cultivation and industry in the world have a long history, the history of the cottonseed industry is short, beginning when the cotton gin was invented. Cottonseed treatment, especially the linters removal method, was developed at the end of the eighteenth century, and it was only at the beginning of this century that the cottonseed industry began to develop into a true industry. It developed first in the United States and then spread gradually to other cotton cultivating countries. Until the development of the cottonseed oil industry, cotton mills disposed of the cottonseed produced, which created an environmental pollution problem. In the 1870s, some cotton cultivating states in the United States regulated the disposal of cottonseed into rivers by state laws.

B. COTTONSEED PRODUCTION AND EXPORTS

Since cottonseed is a byproduct of cotton, its production roughly parallels cotton production. Area under cultivation, yield and production of cotton by country are shown in Appendix Table 1,1) and cotton-seed production is shown in Appendix Table 2.

According to Appendix Table 1, the USSR, the United States and China are the major cotton producing countries, accounting for the majority of the world production. As for cotton yield, the USSR has a particularly high yield (seed cotton, 3.1 tons/ha), which is nearly twice as high as that in the United States and China.²⁾ The yield in India is 0.5 tons/ha, the lowest.

In cottonseed production, as in staple cotton production, the USSR, the United States and China are the three major producing countries, followed by India, Pakistan and Brazil. Together these six countries account for nearly 80% of world cottonseed production. The production of these six countries is shown as a three-year average (1979-1982) in Table B-1 below:

- The unit of cotton in Appendix Table 1 is seed cotton. The unit of cotton in Appendix Tables of other chapter (i.e., [5] Cotton) is staple cotton or ginned cotton. The sources for staple cotton statistics is different from those used for seed cotton.
- 2) The reason for the high yield in the USSR is that since Central Asian republics (Uzbek, Turkmen and Kazakh), which are the major staple cotton producing areas in the country, have high temperatures and are dry, cultivation is done with well-equipped irrigation systems which collect water from rivers and canals. Also, it is said that a sharp difference in temperature between night and daytime is favorable to cotton cultivation.

Table B-1 Cottonseed Production in Main Producing Countries

						(1,000	tons)
USSR	USA	China	India	Pakistan	Brazil	Other countries	World total
-,	5,031 (19.2%)	4,865 (18.6%)			1,150 (4.4%)	5,848 (22.2%)	26,223 (100%)

Source: From Appendix Table 2-(1)

The cottonseed produced is mostly crushed in the producing countries and is partly exported in the form of seed. World exports in the form of seed account for 1% or less of the total production.

In addition to being crushed in the producing countries, some seed is used as feed and as fuel, the quantity of which is estimated at 25% or less of production.

Cottonseed exports by country are listed in Appendix Table 2-(2), which shows that only the United States and the USSR are exporters among the main producing countries, and together account for the largest part of exports, the rest of which is shared by many other producing countries with a small amount of exports each. In small producing countries also, there has been a tendency for the amount crushed domestically to increase and for cottonseed exports to decrease.

The average exports over the past three years by major producing countries are shown as follows:

				(1,000	tons)
USA	Thailand	USSR	Mali	Other countries	World total
74 (37.0%)	39 (19.5%)	36 (18.0%)	19 (9.5%)	32 (16.0%)	200 (100%)

Table B-2 Cottonseed Exports by Major Producing Countries

The largest importing countries are Japan and Mexico, accounting together for a little more than 70% of the world imports.

C. COTTONSEED OIL PRODUCTION AND EXPORTS

Three countries, the USSR, China and the United States, which are major cottonseed producing countries, are also major cottonseed oil producing countries, together accounting for the majority of world cottonseed oil production.

Among these three countries, the USSR consumes almost all of its production and China exports only a minor part of its production, whereas the United States exports almost half, being the largest cottonseed oil exporting country in the world.

The exporting country second to the United States is Brazil, which exports about 40% of its production. In addition to these, there are many exporting countries such as Paraguay, Argentina and Israel, where the export ratio is generally high.

The production and exports and imports of cottonseed oil are shown in Appendix Tables 2-(3) and 2-(4), respectively, and the oil production, exports and imports in the main producing countries (averages in 1979-1981) are shown in Tables C-1, C-2 and C-3 below:

·						(1,000	tons)
USSR	USA	China	India	Brazil	Pakistan	Other countries	World total
648 (21.6%)	599 (20.0%)	417 (13.9%)	272 (9.1%)	150 (5.0%)	138 (4.6%)	778 (25.8%)	3,002 (100%)

Table C-3 Cottonseed Oil Imports and Share of Main Countries

Source: Oil World

D. COTTONSEED OIL CONSUMPTION AND IMPORTS

Cottonseed oil is used as cooking oil, as salad oil, and in mayonnaise, margarine and shortening. When it is used as a material for margarine and shortening, it is cured by hydrogenation to raise the melting point. It is also used in canned foods, especially oil-preserved sardines and tuna.

Cottonseed oil consumption by year and country is derived from the disappearance, which is calculated by using the formula: Beginning stock + Production + Imports - Exports - Ending stock = Disappearance.

The disappearance estimated by <u>Oil World</u> and by the U.S. Department of Agriculture (USDA) is shown in Appendix Tables 2-(5) and 3, respectively, the latter showing disappearance in the main countries.

According to these estimates, cottonseed and cottonseed oil producing countries have a high consumption of cottonseed oil. The latest USDA statistics on the consumption of cottonseed oil as an edible oil by country (1981) show that the USSR, which uses almost all of its production within the country, and China have the highest consumption (USSR 690,000 tons, China 590,000 tons), but the United States, which exports more than half of its production, has a consumption of about 250,000 tons. Consumption as an edible oil is from 100,000 to 200,000 tons in India, Pakistan and Brazil. It is noted that Egypt, which imports cottonseed oil to supplement its domestic production, has a consumption of 330,000 tons, more than that of the United States. Mexico, which imports the oil to supplement that from domestic cottonseed crushing, has a consumption of about 100,000 tons.

Cottonseed non-producing countries consume little cottonseed oil. Among cottonseed non-producing countries, Japan is the largest consuming country. Japan imports both cottonseed for crushing, and cottonseed oil.

Since trends in Japan's cottonseed oil consumption provide a good model of the consumption patterns of cottonseed oil, they are described below.

In Japan, cotton was cultivated domestically until the end of the last century, and cottonseed oil has been used since long ago. At the beginning of this century, cotton cultivation in Japan almost stopped, and consequently Japan began to depend on cotton imports for material for cotton spinning, and simultaneously to import cottonseed for oil extraction. Imports gradually increased, and Japan has become the largest importer of cottonseed in the world.

However, in the latter half of the 1960s, and especially in the 1970s, as cottonseed producing countries increased their domestic oil extraction, Japan has had increasing difficulty in obtaining materials, which has led Japan to turn to various sources of imports. The trends are shown as follows.

Ģ

As shown in the above Tables, the difficulty in obtaining cottonseed caused a decrease in domestic crushing and an increase in oil imports, and the domestic supply has continued to increase on the whole. This increase is due to the increase in the use of cottonseed oil as a home cooking oil and as a salad oil, but with regard to its use in processed foods such as shortening and margarine, oil consumption has decreased. This is attributed to changes in the average family's eating habits, especially the adoption of salad dishes, and to the substitution of other oils for cottonseed oil in processed foods.

E. COTTONSEED OIL PRICE

Cottonseed oil, which is one of the so-called premium oils, is the second most expensive edible oil, almost equal in price to sunflower oil, following peanut oil. The following Table shows the annual average price of cottonseed oil over the past decade.

1960	235	1970	354
1961	305	1971	392
1962	266	1972	324
1963	243	1973	500
1964	250	1974	939
1965	278	1975	726
1966	333	1976	593
1967	378	1977	622
1968	305	1978	661
1969	291	1979	798
		1980	657

Table E-1 Annual Average Price of Cottonseed Oil

Source: Oil World Digest

It goes without saying that the price is determined fundamentally by the balance of supply and demand; and moreover, regarding the supply of vegetable oils, the fluctuation in the production of oilseeds is the major factor. As already stated in the section of General Description on Oilseeds and Oils of this chapter, the production of perennial crops such as palm and coconut palm is more stable in supply than that of annual crops. Oilseed production from annual crops is generally more responsive to price than that from perennial crops. In other words, a rise or fall in price encourages or discourages the producers with regard to production in the following year.

However, cottonseed and cottonseed oil are somewhat different from other vegetable oils in price formation due to their being byproducts of staple cotton production. That is, cottonseed production is strongly bound to staple cotton price rather than to the prices of cottonseed and cottonseed oil. This means that cottonseed production has extremely weak, if any, responsiveness to price.

F. CONCLUDING REMARKS

As already stated, cottonseed oil, which is a high-quality edible oil, one of the "premium oils", as is peanut oil, holds a strong position in its use as a salad oil and cooking oil, as does peanut oil. Accordingly, it may be considered that its future prospects for demand are the same as those for peanut oil, as considered in the preceding part of this chapter. A difference, however, is that peanut is used as a food as well as for crushing, whereas cottonseed is used exclusively for crushing.

From the point of view of production, cottonseed depends on the production of staple cotton as previously mentioned, and as considered in other parts of this Study (the chapter on Cotton), if the production of staple cotton continues to slowly increase in the future, cottonseed production will increase at about the same rate. If the supply increases at such a rate, the share held by cottonseed oil in the vegetable oil market would decrease.

As already stated in the section of General Description on Oilseeds and Oils, in the case of oil plants in general, production trends are subject to the governmental policies of the producing country, such as price support and production control and encouragement, as well as to economic factors; but in the case of cottonseed, the production trends are subject to similar policies on cotton in the producing country.

The United States adopts such policies as production control and price support for staple cotton, as it does for main grains and for peanuts, and many producing countries also use price supports or production subsidies in some form (see the chapter on Cotton).

If cottonseed production increases along with the production of cotton, some countries may export cotton but crush the cottonseed and consume the oil within the country, while some countries may do the opposite. Thus future cottonseed supply and demand will vary depending on which area or country increases or decreases production of cotton in the future.

As mentioned in the section of General Description on Oilseeds and Oils, though future oil consumption is forecasted to grow greatly in developing countries, it is not expected that these countries will import such an expensive oil as cottonseed oil for consumption, except for such countries as Egypt, where cottonseed oil is domestically produced to some extent and where the people have acquired a taste for it for a long time. If a developing country, however, expands production of cotton, with a resulting increase in cottonseed production, an increase in the consumption of cottonseed oil would be possible in that country. On this point, Thailand, the Philippines and Indonesia are of interest. These three countries, although their lands are not suitable for growing cotton plants, plan to increase production of cotton as part of their agricultural policies.

These three countries aim to achieve for self-sufficiency in raw cotton by increasing the production of staple cotton, since they depend almost entirely on imports for cotton, though their spinning industries have already developed considerably with the advance of industrialization. As a result of such policies, the production of cottonseed as a byproduct is expanding in these countries, and cottonseed exports to Japan from Thailand and the Philippines have recently soared.

In summary, it seems that world production of cottonseed oil will slowly increase along with the slow increase in the production of cotton, and regarding consumption, cottonseed oil may be replaced by soybean oil and others in the processed oil sector (margarine and shortening), but it will maintain its position as a cooking oil and salad oil, allowing the increase in production to be alsorbed in consumption.

[1-2-4-4] CORN OIL

A. INTRODUCTION

As corn oil is obtained from corn germ (a byproduct of the corn processing industry, from the production of such items as cornstarch), it is to be called more precisely as "corn germ oil".

The proportion of oil in corn is 2.5 to 3.0%, a very low quantity, as shown in Fig. A-1. An increase in demand for cornstarch necessarily leads to an increase in the production of the material corn germ, leading to an increase in corn oil production.

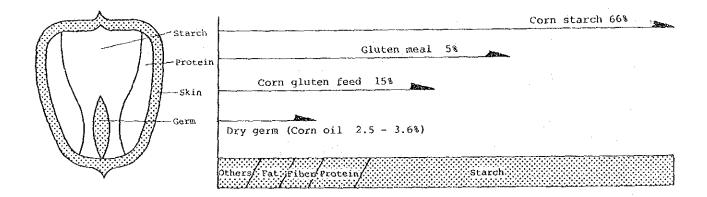

Fig. A-1 Components of Corn

Oil extraction is carried out in or near cornstarch mills, since corn germ deteriorates in quality (e.g. by oxidation) if it is left unused for a long time. Accordingly, there is little marketing of corn germ for use in oil extraction.

Features of corn oil are that it contains a relatively high proportion of nonsaponifiable matter and a very high proportion of unsaturated fatty acids, as do other germ oils. Unsaturated fatty acids account for 80% or more of the total. Of the unsaturated fatty acid content, 50 to 60% is linoleic acid and the rest is oleic acid with no linolenic acid; thus, corn oil may be said to be an oleic-linoleic type oil. It is known that polyunsaturated fatty acids such as linoleic acid are efficacious in inhibiting the rise of cholesterol, but it has been said recently that the phytosterols in nonsaponifiable material also have an important function. Corn oil also contains 0.1% of tocopherols, or Vitamin E, of which 80 to 90% is -type, which is highly anti-oxidative. This is why it keeps for a relatively long period and has good thermal stability, although it contains much unsaturated fatty acid.

Thus the image of corn oil as a health food is very familiar to consumers, and corn oil now holds a stable position as one of the premium oils throughout the world, with its bright yellow color, distinctive flavor and taste. Especially in the United States, which is the largest producing and consuming country, there is a deep-rooted demand for corn oil as an expensive edible oil.

Corn oil is used mainly as a food, as a high-quality salad oil, in margarine, in shortening, in mayonnaise and as a frying oil; in addition, a small amount is used in medicines.

B. PRODUCTION

The fact that it is the byproducts which are used as materials for extraction, as is also true for rice meal oil and cottonseed oil, limits the number of corn oil producing countries. The following pages describe production on the basis of U.S. and Japanese data (Appendix Table 1), and production during the 1972-1977 period based on the FAO Food Balance Sheet.

According to USDA data, the world production of corn oil nearly doubled from 277,000 tons in 1969/70 to 525,000 tons in 1981/82. During this period, the annual average rate of increase was 5.5%, showing steady growth, although production fell in 1974/75 and soared in 1975/76. The decrease in 1974/75 is attributed to the decrease in production in the United States (by 30,000 tons from the previous year), due to a severe drought which caused a sharp decrease in corn production in that country. The share of corn oil in world edible vegetable oil production (USDA data) showed a decreasing trend, from 1.13% in the first half of the 1970s to 0.98% in 1975, but since 1976, it has remained at around 1.3%, and this level of production is expected to continue in the future. Fundamentally, however, production may depend on trends in the production of corn and cornstarch in the United States.

Among the producing countries, the United States produces by far the most corn oil. According to USDA data, this country has held a share of 71 to 78% of world production for thirteen years. This is because the United States is the top corn producing country in the world, and cornstarch production is high. The uses of corn, except as a feed, in this country are as listed below, and around 70% goes to wet milling (cornstarch production).

Table B-1 Uses of Corn in the United States - excluding feed

Source: USDA

The share held by the United States of world corn oil production fell from around 77% in the early 1970s to around 72% in recent years. This indicates an expansion of production in other countries.

According to FAO data, the country following the United States in output is South Africa, which produced 50,000 tons in the 1972-1974 period (three-year average) and 100,000 tons in the 1975-1977 period (same). South Africa is also one of the main corn producing and exporting countries and has had a cornstarch industry since relatively early days.

Japan's corn production is relatively high, and according to MAFF data, was in the range of 25,000 to 30,000 tons without any major increase until 1975, but as a result of the substantial increase in

cornstarch production after 1976, corn oil production expanded remarkably in the second half of the 1970s, and reached 71,000 tons in 1981. The increase in cornstarch production after 1976 was due to the increased demand for starch for saccharification in the production of sugars such as glucose and isomerized sugar, and at present 70% or more of the demand for starch (including saccharified starch) is met by cornstarch. The uses of corn in Japan, except as feed, are shown below. Around 75% is supplied to the cornstarch industry.

Table B-3 Uses of Corn in Japan other than Feed

Source: Same as Table B-2

Other producing countries are the Federal Republic of Germany, Belgium, Luxemburg, France, the Netherlands, Italy and the United Kingdom in Western Europe, Yugoslavia and Czechoslovakia in Eastern Europe, and in South America, Venezuela, a country whose production exceeded 10,000 tons in the 1975-1977 period (three-year average; FAO data).

C. CONSUMPTION

The greatest portion of corn oil consumption is as a food. Corn oil is established as one of the premium oils and is traded at high prices in developed countries. According to FAO's Food Balance Sheet, however, the food to non-food ratio of world corn oil consumption, which was 89 to 11 in the 1972-1974 period, and 82 to 18 in the 1975-1977 period, shows a tendency for non-food consumption to be slightly on the increase.

Table C-1 Consumption by Country

Source: FAO, Food Balance Sheet

[1]-418

Corn oil consumption by country most closely follows production in the case of the United States, which has maintained a production of 240,000 to 300,000 tons since the middle of the 1970s. It is only since the mid-1970s that corn oil consumption grew in this country, having leveled off at around 190,000 to 200,000 tons in the 1960s and the first half of the 1970s. The greatest proportion is used as food. Direct use as a food is the largest, occupying 49 to 69% of corn oil consumption in the past decade. Consumption of the oil as a material for margarine is also established, at around 100,000 tons over the past five years. The share held by corn oil among the oils used for margarine was 10 to 12% from 1970-1980, and consumption in this area has increased at an average annual rate of 1.8%. In addition, corn oil is used as a material for shortening, but this use has been decreasing since the peak of 6,000 tons at the end of the 1960s. Consumption of corn oil in the non-food sector leveled off at a little less than 20,000 tons in the 1970s.

According to FAO data, South Africa, the consuming country second only to the United States, doubled its corn oil consumption from 46,000 tons in the 1972-1974 period (three-year average) to 95,000 tons in the 1975-1977 period (same). Although the ratio of non-food to food uses of corn oil was 91 to 9 in 1972/74 and 78 to 22 in 1975/77 (three-year averages; FAO data), the recent trend in consumption is said to be centered on the food sector.

Japan's corn oil consumption has expanded since 1976 as a result of the expansion in oil production accompanying an increase in the production of corn germ, and reached 65,000 tons in 1981. Consumption stood at 27,000 tons in 1975, before which it was much less, and doubled in the second half of the 1970s. Corn oil in Japan had been regarded as low-class oil, equal to or lower than soybean oil until the first half of the 1970s, and had been principally used as an extender to increase the volume of food oil. For some time before that, corn germ had been used as feed without extracting oil.

The growth of consumption in the second half of the 1970s was due to the increase in corn oil production resulting from expansion in the cornstarch industry. Another factor is that linoleic acid was favorably evaluated and sellers promoted the image of corn oil as a health food. A little less than 70% of corn oil is consumed as edible oil, not mixed with other oils, and about 30% is used as a material for margarine and shortening.

D. TRADE AND PRICE

I. Trade

It is only since 1980 that FAO Trade Yearbook have covered corn oil, because the absolute volume of its trade is very small, though the proportion of trade to production is relatively high. According to the statistics, trade in corn oil has shown a gradual increase from 150,000 to 220,000 tons over the past three years.

On the basis of FAO data and USDA's, the main countries' exports and imports of corn oil are described below.

The United States is the largest exporting country; its exports have rapidly increased in the past three years, with its share of world exports increasing from 25.2% in 1978 to 31.5% in 1980 (FAO data). According to USDA data, exports in the 1980-1981 period were 82,100 tons, 206% times the level of exports in 1977-1978, at 39,900 tons. The growth of exports since the second half of the 1970s is remarkable.

According to the U.S. Department of Commerce's data, the countries of destination of United States exports are developed and petroleum-producing countries such as Canada, the Netherlands and Saudi Arabia. The United States is an exporter of soybeans, soybean oil and various other kinds of oilseeds and oils, and the share of corn oil in the sum of these exports showed a tendency to increase on the whole, despite yearly fluctuations, in the period between the second half of the 1970s and the beginning of the 1980s, from 3.9% in 1975 to 6.6% in 1981 (Appendix Tables 3 and 4).

Following the United States, South Africa, Singapore, France, Belgium-Luxemburg and the Netherlands had exports exceeding 10,000 tons in the past three years, and these countries, including the United States, accounted for 88% of world exports in 1980 (FAO data). Besides these countries, Brazil, the Federal Republic of Germany, Sweden and Zimbabwe, which export corn oil, are new producing countries.

Imports are large to such petroleum-producing countries as Saudi Arabia, the United Arab Emirates and Kuwait, which together accounted for 31% of the total in 1980. Their share, which was 21.6% in 1978, has shown a rapid increase since the latter half of the 1970s. Other major importing countries, except for Italy, Canada and Hong Kong, not only consume the imported oil but also re-export it. Table D-1 World Exports and Imports of Corn Oil

II. Price

Since there is no international corn oil exchange, there is no guiding international prices for corn oil. However, the trading price in the United States, which is the greatest producing, consuming and exporting country, influences the world corn oil price. Among dealers, the ex-mill price in Midwest Mills at the center of the United States' processing industry, provides a guide for the trading price.

Trends in the price of corn, which is the primary material (as the source of both corn oil and corn germ), and in the price of cornstarch, which provides corn germ as a material for corn oil, need to be considered, in addition to corn oil supply and demand and trends in other edible vegetable oils, as determinants of the corn oil price.

Factors related to the corn price are: a. supply and demand in the United States and Chicago markets; b. purchases by centrally planned economies such as the USSR and China; c. the climate in the corn belt in the United States; and d. the development of the use of corn for alcohol fuel in the United States. Factors related to the cornstarch price are: a. the demand for isomerized sugar; b. the development of new uses for processed starch; c. competition with potato starch in Europe; and d. developments in the production of starch from cassava, sweet potato, sago palm and the like.

The United States export prices of corn oil and soybean oil, and the conditions of the Chicago corn market are shown in Appendix Table 5 and Appendix Fig. 1. Although corn oil holds a special position, its price movements are similar to those of soybean oil and other edible oils. The price correlation between corn as the primary material and corn oil is not strong in the United States, but may be stronger in corn oil producing countries which are dependent on imports of corn for the primary material.

E. CONCLUDING RAMARKS

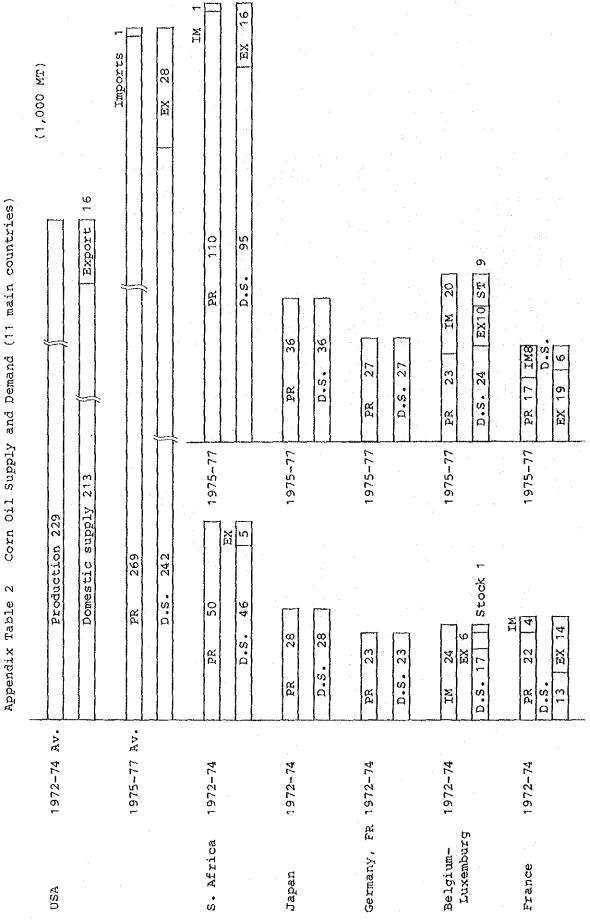

Corn oil has come to be highly regarded due to a recent improvement of the image of vegetable oils (centered around linolic acid) as health foods, in contrast to the past image of corn oil as merely one of the mixing oils, receiving little attention. However, the increase in production is not necessarily the result of an expansion in demand, but rather demonstrates the character of corn oil as a byproduct similar to cottonseed oil.

Accordingly, future trends in corn oil supply and demand may depend on the balance of supply and demand for cornstarch, which is the primary product. That is, if corn oil production increases as a result of an increase in cornstarch production, and exceeds demand, the price will fall below that of other premium vegetable oils, and as a result, consumption of corn oil as a substitute for other premium oils will grow. Conversely, if the price of corn oil rises, the other premium oils will be used as substitutes for corn oil.

[1-2-4-5] CASTOR BEANS

A. INTRODUCTION

Castor (scientific name: Ricinus communis) is a plant which falls under Euphorbiaceae. Its origin is said to be Africa, and it had been already cultivated to obtain fuel oil in Egypt in the pre-Christian era. It was for castor oil as a medicine (purgative) that castor began to be widely cultivated throughout the world. However, today castor is used mostly in industry.

Castor is an annual herb in the temperate zone, but is a perennial in the form of an evergreen shrub in the tropical zone. The length of the stem is between 1 m and 7 m, but some stems exceed 10 m in the tropical zone.

Although high temperatures are favorable to castor, it is cultivated not only in the tropical zone but also in the temperate zones. In the latter, it requires a growing period of 140 to 180 days without frost. Areas with too much rain and waterlogged areas are unsuitable for castor.

As shown in Appendix Table 1, castor is widely cultivated all over the world, although three countries, Brazil, India and China, account for 76% of the world area under cultivation. Appendix Table 1 also shows that the yield per unit area varies greatly from country to country: Brazil and Thailand produce a crop of about 700 kg/ha, whereas India produces the lowest crop (230 kg/ha), with China (432 kg/ha) and the USSR (432 kg/ha) occupying the middle position.

The castor cultivation is generally of small-scale, though there are large-scale plantations in Brazil and China. Since the difficulty in mechanizing the harvesting of the beans necessitates hand harvesting, the merit of large-scale plantations is small. In the United States, however, mechanised large-scale cultivation is carried out using dwarf hybrid suitable for mechanical harvesting. In the wet tropical zone (e.g., Thailand, Indonesia), harmful insects, particularly the insect called American Army Worm (Arhaea janata), are a great enemy of castor, and large-scale cultivation is more vulnerable to such danger. The harvesting time for castor varies by country. The standard harvesting time in the major producing countries is shown in the following Table.

Country	Harves	ting time
Romania	July	to September
USSR	July	to September
Ethiopia	October	to becember
Sudan	February	to May
Tanzania	Мау	to August
Mexico	July	to November
Brazil	May	to September
Ecuador	September	to December
Paraguay	May	to September
China	July	to January
India	December	to May
Pakistan	December	to May
Philippines	September	to December
Thailand	September	to December

B. CASTOR BEAN PRODUCTION, EXPORTS AND IMPORTS

Brazil, India and China are the three major producing countries in terms of the area under cultivation, accounting for 76% of the world area under cultivation and 75% of the world production. The USSR, Thailand, the Philippines and Paraguay are the other main producing countries (Appendix Table 1).

According to the graph of trends in production over the last five

years, shown in Fig. B-1, although world production increased from about 700,000 tons in 1976/77 to 900,000 tons in 1980/81, this increase was achieved in the first half of the period (from 1976/77 to 1978/79), and production leveled off in the second half.

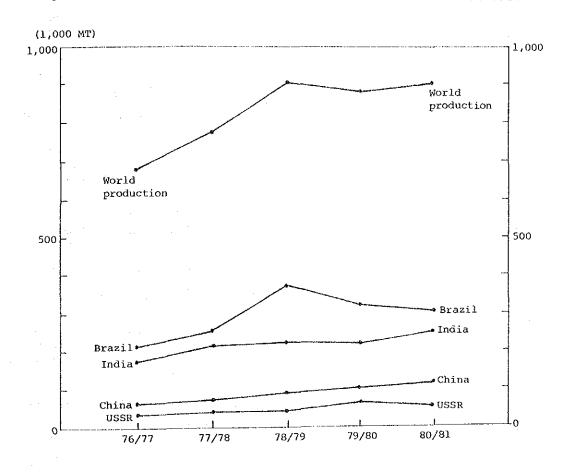

Fig. B-1 Trends in World Castor Beans Production in 1976-1981

Source: Figures taken from Oil World

In Brazil, which is the largest producing country, the production increased remarkably in the first half of the above period, but tended to decrease in the second half.

In India and China, production slowly increased through the entire period. In the USSR, the increase was marked in the second half. All producing countries increased their production except for Thailand and Pakistan, which registered decreases in the above five-year period. The continued decrease in production in Thailand in 1978/79 and 1979/80 can be attributed to ban on castor bean exports imposed by the government to accomodate the newly-built domestic castor oil extraction mills, which caused the domestic price to fall and discouraged farmers from producing castor.

Castor bean exports and imports over the last five years are shown in Tables B-1 and B-2, respectively.

Table B-1 Castor Bean Exports by Main Producing Country

Comparing exports with production in recent years (1980-1981), the total world production was about 900,000 tons, whereas exports stood at around 60,000 tons, accounting for only 6.6% of the total production. This means that almost all castor bean is crushed in the producing countries.

ŝ.,

Brazil, India and the USSR, which are major producing countries, do not export castor bean at all. Although Thailand had been the largest exporter until several years ago, its exports have been zero since 1979/ 80 as a result of the introduction of domestic crushing as mentioned above.1)

 Brazil and India have banned castor bean exports for some time, but Thailand was exporting its entire castor bean production because of the lack of crushing facilities. In 1979, however, Thai Castor Oil Industries Co. (TCO) was set up as a joint venture between the West German Boley Co. and Thailand, and castor bean exports are now controlled by an export license system. In the subscription of capital for TCO, the ratio of Thai to West German capital is 65 to 35. Table B-2 Castor Bean Imports by Main Importing Country

Source: Oil World

As shown in Table B-2, the main importing countries are the EC countries (especially the Federal Republic of Germany), Japan and Brazil. Although Brazil is the major producing country of castor bean, it compensates for shortages in the supply of materials for domestic crushing with imports. The EC countries and Japan do not produce castor bean and depend entirely on imports.

Since the castor bean producing countries have converted from castor exports to oil exports (which have higher value), countries dependent on imports of castor, such as the EC countries and Japan, have had increasing difficulty obtaining castor for crushing. As a recent example, the Japanese industries which depended largely on Thailand for castor bean have recently purchased bean from other sources, especially the Philippines and China, as Thailand stopped the export of castor bean.

Recent changes in sources of castor bean imports to Japan are shown in Tables B-3 and B-4 below. In this context, Appendix Table 1 shows that production in the Philippines has rapidly increased as a result of Japan's purchases.

The Federal Republic of Germany, which like Japan, depends on imports for its supply of castor bean, used to depend mainly on Paraguay as its source of supply, but recently has been purchasing from the Philippines as well.

C. CASTOR OIL PRODUCTION, EXPORTS AND IMPORTS

1. Properties and Uses of Castor Oil

Castor beans contain the toxic protein ricin and the alkaloid ricinin, and 30 to 60% of oil.

Castor oil is a non-drying oil containing 80 to 90% linolenic acid, and it has special uses different from other vegetable oils because of its linolenic acid content. The meal, which is a byproduct of oil extraction, is too toxic to be used directly as a feed, but is used as a fertilizer.1)

Castor oil has been known for its medicinal (purgative) properties since ancient times, but today its use as a medicine is negligible; and it is almost exclusively used as a material for industry.²)

The principal properties of castor oil as an industrial material are as follows:

- a. Viscosity: It has much higher viscosity than other oils, and forms a good lubricative surface.
- b. Stability: It is relatively stable in sunlight, air and heat.
- c. Electrical properties: It has good values in specific inductive capacity, volume resistivity and dielectric power factor.
- d. Resin solubility: It is soluble in many resins such as nitrocellulose, rosin, shellac and polyamides.
- e. Solvent solubility: One of the features of castor oil is that it is highly soluble in alcohol, ketonic ether and esters, especially in alcohol.
- f. Hydrophilic properties: Castor oil is the most hydrophilic of the vegetable oils, which is favorable for the protection of skin and hair.
- The removal of harmful components from the meal can be done relatively simply by heating, and the detoxicated meal can be used as fertilizer.
- 2) The removal of hydroxyl groups from castor oil by chemical treatment provides high-quality edible oil, but is costly.

These properties provide a range of castor oil uses for industry which is very wide and diverse. An outline is shown below, although the proportion of each use varies with country and time. In Japan, for example, applications in paints and in textile processing (as a dyeing solvent) account for a large proportion (about 30% each), but in France, almost all castor oil is used as material for 11-Nylon (trade name "Rilsem") by ATO Chemical Co.¹ (Appendix Fig. 1).

II. Castor Oil Production

Castor beans are treated (crushed) in both the producing and the importing countries, and volume of crushing in the world and in the main countries is shown in Table C-1. The volume crushed in Brazil is the largest, followed by India and China. In other words, the major producing countries of castor bean are also the major crushing countries. Among castor bean importing countries, Japan and the Federal Republic of Germany are the main crushing countries.

Source: Oil World

 In Japan also, castor oil is used as a material for nylon, in the sebacic acid type 6-10 Nylon used mainly for fishing nets. Japan also imports 11-Nylon from France for use in pipes in automobiles. 11-Nylon is said to be more flexible and more suitable than polyvinyl chloride as the material for such pipes. Oil production corresponds to the crushing mentioned above, and is shown by main countries in Table C-2. Trends in production in recent years are shown in Fig. C-1.

Table C-2 Castor Oil Production by Main Country

Source: Oil World

[1] - 441

The above graph naturally shows almost the same movements as the graph of castor bean production in Fig. B-1: production rose in 1976-1978, after which it fell in Brazil and leveled off in India. The large increase in Brazil in 1978/79 was the result of a heavy crop of castor bean in Brazil in that year.

III. Castor Oil Exports and Imports

Castor oil exports and imports are shown in Tables C-3 and C-4. In exports too, Brazil ranks first, accounting for 60% of the total. Brazil and India (which ranks second) together account for 90% of the total.

China began to export castor oil (4,000 tons) in 1977/78, and subsequently, China's exports increased from 6,000 tons to 8,000 tons.

In castor oil imports, the United States ranks first, followed by France. The United States and France annually import about 50,000 tons of castor oil, and the USSR imports slightly less than 30,000 tons.

IV. Castor Oil Demand

Castor oil demand 1) after the adjustment of castor oil exports and imports is shown in Table C-5. The total world demand is about 340,000 tons, and there has been no major change in the last five years.

Since castor oil is used for industry, demand comes from industrialized countries, and the EC, the United States and the USSR hold the largest share, as shown in Table C-5. These industrialized countries meet their demand by importing the oil or the bean. Although the USSR is one of the major producing countries of castor bean, demand there is met by supplementing domestic production with imports.

Brazil, China and India, which are major producing countries of both castor bean and oil, meet their own domestic demand and export their surplus oil. In these countries, domestic demand has tended to gradually increase along with the advance of industrialization, in contrast to the stagnation or decrease in demand seen in the industrialized countries.

The demand by country was estimated by using the formula: Beginning stock + Output + Imports - Exports - Ending stock.

Table C-5 Source:

[1] - 444

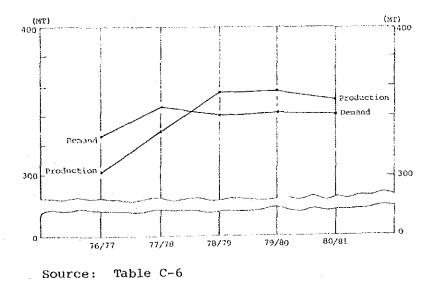

A comparison of the total world production and demand for castor oil is shown in Table C-6 and Fig. C-3. In the last five years, production has changed by a factor of 6.1%, whereas demand has only slightly changed by a factor of 1.93%. This indicates that castor oil demand has been stable during that five-year period.

Fig. C-3 World Castor Oil Production and Demand

CASTOR OIL PRICE D۵

Ex-tank price at Rotterdam is generally used as the standard international market price of castor oil. Monthly and annual average prices since 1969 are shown in Appendix Table 2. These prices and world castor oil production are graphed in Appendix Fig. 2.

As shown in the price graph, there was an unusual rise in 1973, which was the result of a chain reaction of the oil crisis, a rise in the prices of petroleum products having a substitutive relationship with castor oil, and difficulty in procuring transport tankers. This price increase stimulated production, which soared to more than 1 million tons in 1974. The excessive supply which resulted from this increased production caused the price to fall, resulting in production dropping to a low of 620,000 tons in 1976. Subsequenly, both the price and the production level recovered, and have shown no major change since.

There are strong substitutive relationships between the various vegetable oils, and the price of soybean oil in particular has a large influence on the prices of other oils, as already mentioned. Since castor oil is, however, not used for food but only in industry, it has little substitutive relation with other oils, and hence its price is independent of the prices of other oils.

In attempts which were made to estimate the correlation coefficient in the monthly average price between October 1979 and September 1980, no correlation was found between soybean oil and castor oil (chosen to represent vegetable oils), as shown in Table D-1.

Castor oil is an expensive oil, second only to olive oil in price among the vegetable oils. Average prices of oils in 1980 were as follows:

Olive oil	\$2,500/MT
Castor oil	1,114
Peanut oil	863
Palm oil	674
Coconut oil	673
Cottonseed oil	657
Sunflower oil	632
Soybean oil	598

E. CONCLUDING REMARKS

As mentioned above, castor oil has a specialized demand from industry because of its properties, and since there is little substitutive relationship with other oils (vegetable and animal oils), castor oil demand is relatively stable.

In terms of its uses in industry, however, castor oil has a substitutive relationship with petrochemical products, and in some areas, castor oil demand increases or decreases accoridng to its price relative to that of petroleum products. For example, ll-Nylon, made from castor oil, has a competitive relationship with 12-Nylon made from petroleum, because they have common uses. The uses of castor oil, however, have been diversified over the years as already stated, and castor oil appears to have potential for new uses through future development.

On the other hand, the production in the world and in the main producing countries has tended to increase slowly. As shown recently in the Philippines, there is a possibility of rapid growth of production in the tropical developing countries provided that they can secure markets.

Thus, it may be considered that world production and demand for castor bean will continue to increase slowly in the future.

[1-3] STRUCTURE OF PROJECTION MODEL AND PROJECTED RESULTS

[1-3-1] EXISTING PROJECTION MODELS CONCERNING FATS AND OILS

Among the models that examine agricultural products, particularly oil crops and their products, there are a small number that make projection of production, consumption and trade on a worldwide scale. Of these models, those developed by the World Bank and USDA will be outlined here.

A. THE WORLD BANK; WORLD FATS AND OILS ECONOMY

The World Bank has developed simulation models for the world covering a number of primary products. Of these models, that which examined oilseeds and their products will be reviewed here. The outline is as follows:

1. Objectives of the Model

Forecast of long-term movements of oils and fats, and of highprotein meals in the world markets.

2. Basic Factors of the Model

Before a model is constructed, it is necessary to identify the complex variables that interact in the current market of the commodity that is to be examined. To a great extent, the degree of emphasis that is placed on the numerous relationships within a model depends on the subjective judgment of the designer of the model.

In the construction of this model, emphasis was placed on the following factors:

First, most oilseeds have, in generalized terms, two products fats and oils, and high-protein meals. The demand for fats and oils and that for high-protein meals can be considered as virtually independent. The two levels of demand influence the production of oilseeds independently. In view of the result, however, demand for both commodities and production of oilseed are closely related.

Secondly, in terms of their use as stock feed, high-protein meals and other feed crops are closely related.

Thirdly, as fats and oils are used for a variety of purposes, there is substitutability among oilseeds to some extent.

Fourthly, vegetable fats and oils are extracted from either annual or perennial (tree) crops. These two crop varieties differ in the way their production reacts to the market prices.

3. Agricultural Products Examined

- a. Oilseeds (five annual crops and three perennial crops)
- b. Fats and oils (those obtained from the oilseeds under examination)
- c. High-protein meal (those obtained from the oilseeds under
 - examination)

Also, animal fats and oils and their meals are briefly discussed.

4. Classification of the Regions

The world is divided into eight regions, as follows:

Developing countries East Africa West Africa Middle and Near East, North Africa Latin America East Asia South Asia Developed countries

Countries with centrally planned economies

5. Data Used in the Model

Data on oilseed crops published by FAO and USDA are used. These data are converted into an oil base and a meal base to meet the convenience of mutual comparison between crops and between fats and oils and meals. Each conversion factor assumes the same numerical value regardless of time or region. The conversion factors are listed in Table A-1.

Dilseed Crop	Oil Yield	Meal Yield
<u></u>	(per	cent)
	••	
Soybeans	18.0	79.5
Sunflower Seeds	42.0	55.0
Cottonseeds	17.5	59.0
Groundauts	44.5	55.0
Rapeseeds	38.5	59.0
Copra	63.5	36.0
Palm Kernels	46.5	52.5
Linseeds	34.0	63.0

Table A-1 Oil and Meal Yields

The same oil and meal contents were used to convert oilseed supplies into their oil and meal equivalents. Thus, world fats and oils supplies is the total of the oil equivalents of the various oilseeds and the world supplies of oils, such as palm oil or olive oil, which are extracted from a raw material that has no significant meal component.

Source: Oil World Weekly as cited by the World Bank

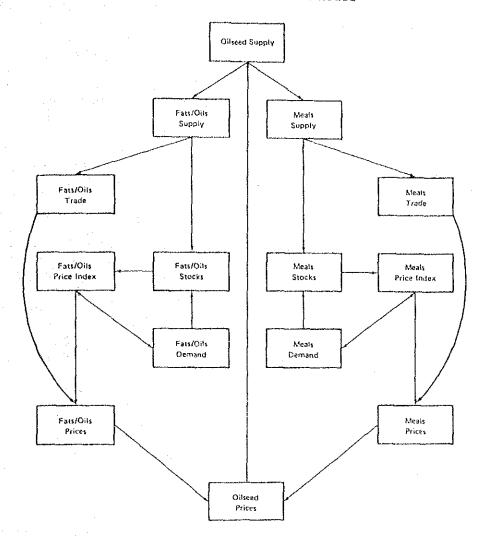

6. Model Structure

This model describes three markets; oilseeds, oils and fats and high-protein meals. Sub-models are constructed for these three markets. Each sub-model consists of three blocks (demand block, supply block and trade block) with the same basic structure (Fig. A-1).

Nerlovian type supply function is employed in the supply block as follows:

 $Qos_t^i = f^i(pos_{t-k}^i, Qos_{t-1}^i, Zt)$ where $Qos^i = world \text{ production of } i \text{ oilseed}$ $Pos^i = price \text{ of } i \text{ oilseed}$ Zt = quantity of supply shiftk = time lag

When the formula is applied for soybeans, the result is as follows:

 $SOYS_t = -11824.9 + 73.1638 SOYP_{t-1} + 0.9133SOYS_{t-1} - 10658.9 D_{75} + 12440.8 D_{76}$ (R² = 0.97 S.E.E. = 2242 D.W. = 1.23) where SOYS = world production of soybeans (1,000 MT) SOYP = soybean price D₇₅ = dummy variable set to 1 for 1975 D₇₆ = dummy variable set to 1 for 1976

Furthermore, a distinction is made between annual crops and tree crops whereby the price variable from the previous year is used in the supply function for annual crops, and a price variable taken from several years previously is used in the supply function for tree crops (Price variables from nine years time lag for olive and palm kernel oils; and price variables from six years time lag for palm oil and seven years for copra oil).

In the demand block, the demand functions are formulated for each commodity in each regional bloc.

The estimation of consumption is computed from disappearance per capita. Per capita disappearance of fats and oils is obtained by the following method. Firstly, the domestic supply is estimated by adding the imports to and subtracting the exports from the overall regional production of oilseeds. Then, the overall quantity of oil available for domestic consumption is calculated from the quantity of oilseeds for extraction and the yield rate. The overall quantity is further adjusted by incorporating export and/or import figures for oil, and the final quantity of oil available for domestic consumption is derived. Therefore, the quantity per capita is found by dividing the final quantity of oil available by population and can be called, per capita disappearance, which is used as a proxy for per capita consumption.

In this model, another important factor to capture the behavior of the fats and oils markets is considered the demand for high protein meals, which is largely a reflection of the demand for animal feeds by the livestock industry. Income is the main economic factor determining the demand for livestock products together with meal prices. This relationship for high protein meal demand is presented below.

 $D_{mt} = \alpha + \beta P_{t-1} + \gamma G + \delta D_{m,t-1}$ where

^Dmt: demand for high-protein meals (protein equivalent) P : price index of high-protein meal (1974 = 100) G : GNP $\alpha, \beta, \gamma, \delta$: estimated parameters

Besides the supply and demand blocks, another characteristic of this model is the inclusion of the total stock of fats and oils and meal. Corresponding to the first consideration in the construction of the model, as mentioned in Section 2, this factor has been included to observe the way demands for fats and oils and high-protein meals influence production. It aims at evaluating movements in demand for fats and oils and high-protein meal in terms of the fluctuations in the stock of each commodity, thereby assessing how the demands influences production and price levels.

Regarding the third consideration in the construction of the model - the substitutability among different kinds of fats and oils substitutability is finally adjusted by the relative price (price index) between the different fats and oils. Most fats and oils can be substituted for another but the degree of substitution depends upon their refining cost and exactly the type of oil or fat wanted by the consumer. Fats and oils have specific properties, physical (odor, color, and melting point, etc.) and chemical (fatty acid content, etc.) which indicate their advantages and disadvantages from the viewpoint of competition with other fats and oils. Consequently, each fat and oil has two markets: firstly, the market in which quality (low substitutability) is the reason for purchase, and secondly, the market in which the fat and oil is sold in competition with other fats and oils. price elasticity is considered to be smaller in the first market than in the second.

Theoretically, the demand for each fat and oil is calculated by the following formula:

 $\begin{array}{l} Q_1 = F_1 \ (p_1, p_2, \ \cdots \ p_k, \ z_1) \\ Q_2 = F_2 \ (p_1, p_2, \ \cdots \ p_k, \ z_2) \\ \vdots \\ Q_k = F_k \ (p_1, p_2, \ \cdots \ p_k, \ z_k) \\ \text{where} \\ Q_i: \ \text{demand for the ith fat or oil} \\ P_i: \ \text{price of the ith fat or oil} \\ Z_i: \ \text{demand shift of i equation} \end{array}$

Parameters estimated by this equation system are cross price elasticity values. Some fats and oils and meal, however, show strong interdependence as indicated in Tables A-2 and A-3. As a result, the problem of multicolinerarity makes it difficult to estimate these parameters. To overcome this problem in the model, the prices of individual fats and oils are incorporated into a single comprehensive price index.

PFO_t is indicated by the following formula;

 $PFO_{t} = \frac{Pit \cdot QFOX_{it}}{P_{i,74} \cdot QFOX_{i,74}} = \frac{VFOX_{t}}{VFOX_{74}}$ where $P_{i,74}: \text{ price of i fat or oil in 1974}$ VFOX_t: export value of fat or oil for t period

7. Projected Results

One of the projected results is shown in Tables A-4 and A-5. It is said that the validity of the basic model was confirmed quantitatively, after investigating the projected results. It was shown that Correlation Matrix of Prices for Selected Fats and Oils /a Table A-2

Source: Oil World

the demand for high-protein meal exceeds that for fats and oils, increases stocks when demand increases, and creates a situation in which the overall price level of the fats and oils is lowered. As a result, the production of oil crops with high oil content falls. Further, the demand for fats and oils in the developing countries increases. The World Bank believes this reduces the stock level of fats and oils and, towards the end of the projection period, raises the overall price level of fats and oils.

As indicated in Tables A-4 and A-5, for the period 1981-85, the production of fats and oils exceeds consumption world-wide but, conversely, in the period 1986-90, consumption overtakes production.

The Tables also show production of vegetable oils will reach 39,485,000 tons in the 1981-85 period and 42,334,000 tons in the 1986-90 period. The World Bank revised its forecast by using the model based on the revised input data (see, "Fats and Oils" of Price Prospects for Major Primary Commodities, Vol II: Food Products and Fertilizers, 1982). The main results are shown in Tables A-6, A-7 and A-8. These tables show that by 1990, oilseed production will reach 62.6 million tons (oil-base), of which 20.9 million tons (33.4% of world production) will be produced in the developed countries, 37.0 million tons (59.1% of world production) in the developing countries and 4.7 million tons (7.5%) in the countries with centrally planned economies.

Similar to projections of the Study Team outlined later, the World Bank's forecast of world production will remain at virtually the same level until 1985 but, thereafter, its forecast of production is higher than our projection.

B. USDA MODEL; WORLD SUPPLY AND DEMAND PROSPECTS FOR OILSEEDS AND OILSEED PRODUCTS IN 1980 (with emphasis on trade by less developed countries)

The United States is the largest agricultural producer in the world and therefore any fluctuations in its annual harvest, or changes in agricultural policy exert an enormous influence on the world food supply. The situation is the same for oil crops. The United States has always been huge supplier of the main oilseeds such as soybean, peanut, and cottonseed. The USDA has, from its early days, sought to develop a model of world agriculture in line with its position as the major supplier of agricultural products. The data collected and analysed in the USDA are regarded with equal significance as the FAO data. One aspect of those data will now be discussed viz., the projection model of production and trade for oilseeds and their byproducts.

1. Objectives of the Model

One of the main reasons that this projection model was constructed, as indicated earlier, is to obtain projections for the production of and trade in, oilseeds in developing countries.

2. Basic Factors of the Model

Investment, and increases or reductions, in oilseed production depend on the size of the return producers expect. Agricultural policies, particularly, price-support ones adopted by individual countries are a very important factor in oilseed production.

The first basic consideration, therefore, is to develop a model that reflects these policies.

The second consideration, though negative, involves the difficulty of estimating the relationship between price and supply of oilseeds. In detail, methods to utilize price elasticity values for supply are inappropriate for commodities such as oilseed which have a variety of uses. Therefore, the projection of oilseed production is based on the analysis of trends in the period 1955-68 by crop and by region (The projection based on the trend in the period 1962-68 is also made, when necessary). An assumption taken in this case is that the forces influencing the past trend of cultivated area and unit yield will continue in the same direction and dimension in the future also. Furthermore, when values extrapolated from the trends are judged to be inappropriate, correction is made by introducing institutional and economic factors of the production level in the region in question (see Table B-2 concerning the projection of trends and adjusted results).

The third consideration, as mentioned earlier, involves determining the prospects of production of, and trade in, oilseeds and oilseed products in the developing countries, as well as estimating the profits the developing countries obtain from the trade in fats and oils, by investigating and comparing price, production, consumption and trade levels assuming three different situations.

The three different situations are classified as Projection Set I, Set II and Set III.

Projection Set I

On the assumption that the present policy for production and trade continues into the future, this set assumes that productivity in developing countries will rise steadily.

Projection Set II

This set fixes agricultural productivity and economic growth rates in the developing countries in 1980 higher than those in Set I.

Projection Set III

The agricultural productivity and economic growth rates in the developing countries in 1980 are fixed lower than those in Set I.

As for economic development and agricultural productivity in the developed countries and countries with centrally planned economies, a single set of assumptions was applied in the three classifications above.

The "projection sets" are based on the third consideration which, naturally, must include the policies undertaken by developing countries. As such, the first consideration is also incorporated into the projection sets.

The fourth consideration is the effect of aid, provided in the U.S. Public Law 480, which exerts on the international price. Through PL 480, a large quantity of vegetable fats and oils is granted to the developing countries. For example, a large quantity of oil (about 350,000 tons) was despatched in 1965 as a concessional shipment. The amount of the aid, taken into consideration with the substitutability of fats and oils, has a big bearing on the world trade in fats and oils.

3. The Agricultural Products Examined

Oilseeds: soybean, peanut, cottonseed, sunflower seed, rapeseed, copra and oil palm

Fats and Oils: soybean, peanut, cottonseed, sunflower seed, rapeseed, coconut, palm, palm-kernel and olive

Oil Meal:

Meals obtained after extraction of oils indicated above.

4. Classification of the Regions

For vegetable oils, the world is divided into eighteen regions as indicated in Table B-1. Furthermore, subtotals are provided for the developed countries, the centrally planned economies and the developing countries respectively. For oil cake, the eighteen regional divisions used for vegetable oils are reclassified into thirteen (By the numbers in Table B-1, regions 7 + 8, 12 + 13, 14 + 15, 16 + 17 + 18are combined).

East Asia and Pacific Islands Brunei, China (Taiwan), Hong Kong, Indonesia, South Korea, Macao, Malaysia, New Guinea, Pacific Islands, Papua, Philippines, and Singapore.

5. Data Used in the Model

The basic data have been taken from both the USDA and FAO.

For soybean production, estimates from the University of Minnesota are used. For cottonseed production, the projected values from Economic Research Service of USDA are used (World Demand Prospects for Cotton in 1980, USDA, Economic Research Service, Foreign Agriculture Report, January 1971).

 $\frac{1}{2}$ / t = 0 at midyear

3/ Mainly 1979 production which will be crushed in 1980 unless designated by an asterisk.

6. Model Structure

The overall structure of this model is indicated in Fig. B-1. In the group of objective variables, the innitial figures of production are obtained by conducting trend projection based on a linear regression formula. Values of trend projection of adjusted projection are shown in Table B-2.

The model is a linear simultaneous equation model and, as indicated in Table B-5, is composed of behavioral, technical and equilibrium equations for both exporting and importing regions. Tables B-3 and B-4 describe all endogeneous and exogeneous variables used in the model.

As indicated in Fig. B-1, the model incorporates a simplified structure to represent the market by dividing it into exporting and importing regions, and computing the demand for fats and oils as well as for meal by region. The variables in this model, however, are numerous and the exogeneous variables, in particular, cover a vast range of factors. It is noted that among the exogeneous variables, the quantity of aid, provided through PL 480, is included as PL^{i} , and also that the beginning stocks of oil and meal are put in.

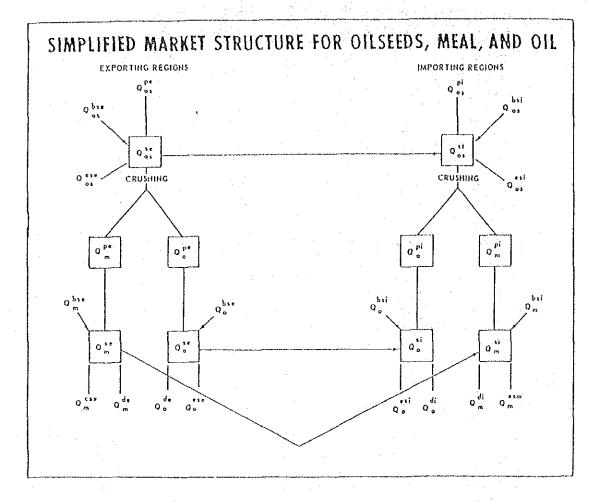

Fig. B-1 Structure of USDA Model

For symbols, see Tables B-3 and B-4.

Since the export and import functions of oilseeds, fats and oils and meals are represented by the equilibrium equations, projected figures for them alway agree each other.

Table B-3 Description of Endogenous Variables

· ·		Tab.	Le	B-3 Description of Endogenous Variables
	1.	Qdi	2	Quantity of oil demanded in importing regions.
	5,	Q _m di	7	Quantity of meal demanded in importing regions.

21.	T _m ≈	Transfer costs for meal,
22.7	т _о =	Transfer costs for oil.
23.	T =	Time (trend variables).
24.	Pi =	Frice of tankage.
25.	$Q_{OS}^{si} =$	Supply of commercial oilseeds.
	· .	

Table B-5 World Model for Oilseeds, Meal, and Oil

Importing Regions

Behavioral Relationship

1.	Demand for oil: $f(Q_0^{di}, P_0^i; P_{sb}^i, I^i, PL^i, Q_f^{ii}, Q_f^{bsi} \dots e_1) = 0$
2.	Demand for meal: $f(Q_m^{di}, P_m^i; A^i, Q_{fd}^{pi}, P_t^i, Q_{fd}^i \dots Q_{fd}^{pi}) = 0$
3.	Production of oilseeds: $f(Q_{os}^{pi}; P_{os}^{i}; t-1, P_{sb}^{i}, T \dots, e_{3}) = 0$
Ц.	Crushing equation: $f(Q_{os}^{ci}, P_{os}^{i}, P_{m}^{i}, P_{o}^{i}; M_{c}^{i}$
5,	Ending stock of meal: $f(Q_m^{esi}, P_m^i; Q_{os}^{si}, \dots, P_{os}^{si}) = 0$
6.	Ending stock of oil: $f(Q_0^{es1}, P_0^i; Q_{os}^{esi}, PL_0^i \dots e_6) = 0$

Technical Relationship

Behavioral Relationship

7.	Production and import for oilseed: $Q_{os}^{pi} + Q_{os}^{ii} = Q_{os}^{ci}$
8.	Crushing for oilseed: $Q_{os}^{ci} = bQ_{la}^{pi} + (1-b) Q_{o}^{pi}$
9.	Market clearing for meal: $Q_m^{pi} + Q_m^{bsi} + Q_m^{ii} = Q_m^{di} + Q_m^{esi}$
10.	Market clearing for oil: $Q_0^{pi} + Q_0^{bsi} + Q_0^{ii} = Q_0^{di} + Q_0^{csi}$

11. Price linkage: $P_{os}^{i} + M_{c}^{i} = bP_{m}^{i} + (1-b) P_{o}^{i}$

Exporting Regions

12.	Demand for oil: $f(Q_0^{de}, P_0^e; P_{sb}^e, I^e, Q_f^{ii}, Q_f^{bsi} \dots P_{lb}) = 0$
13.	Demand for meal: $f(Q_m^{de}, p_m^e; P_{sb}^e, A^e, Q_{fd}^{pe}, P_{fd}^e, p_t^e, \dots, e_{15}) = 0$
14.	Production of oilseeds: $f(Q_{os}^{pe}; P_{os t-1}^{e}; P_{sb}^{e}, T \dots, e_{16}) = 0$
15.	Crushing equation: $f(Q_{os}^{ce}, p_{os}^{e}, P_{m}^{e}, M_{c}^{e}, \dots, \dots, e_{17}) = 0$
16.	Ending stock of oilseeds: $f(Q_{OS}^{ese}, P_{OS}^{e}, Q_{OS}^{se}$ $e_{18}) = 0$
17.	Ending stock of oil: $f(Q_0^{ese}, P_0^e; Q_0^{se}, \dots, P_{o}^{se}) = 0$
18,	Ending stock of meal: $f(Q_m^{ese}, P_m^e; Q_m^{se}, \dots, e_{20}) = 0$

Technical Relationship

19. Supply for oilseed: $Q_{os}^{pe} + Q_{os}^{bse} = Q_{os}^{ce} + Q_{os}^{ee} + Q_{os}^{ese}$ 20. Crushing for oilseed: $Q_{os}^{ce} = aQ_m^{pe} + (1-a) Q_o^{pe}$ 21. Market clearing for meal: $Q_m^{pe} + Q_m^{bse} = Q_m^{de} + Q_m^{ee} + Q_m^{ese}$

Table B-5 (cont'd.)

22. Market clearing for oil: $Q_o^{pe} + Q_o^{bse} = Q_o^{de} + Q_o^{ee} + Q_o^{ese}$ 23. Price linkage: $P_{OS}^e + M_C^e = aP_m^e + (1-a) P_O^e$

Regional Relationships

Equilibrium Conditions

24. $Q_{os}^{ee} = Q_{os}^{11}$ 25. $Q_m^{ee} = Q_m^{11}$ 26. $Q_o^{ee} = Q_o^{11}$ 27. $P_{os}^{1} = P_{os}^{e} + T_{os}$ 28. $P_m^{1} = P_m^{e} + T_m$ 29. $P_o^{1} = P_o^{e} + T_o$

7. Projected Results

Projection Set I

Under the assumption of the Projection Set I, the results are as follows:

- a. The South America region shifts from being a net exporter to net importer.
- b. Exports from the region of East and West Africa, and East Asian/ Pacific region increase at the annual rate of 1.0% and 2.1% respectively.
- c. Japan, Central America, North America, West Asia and South Asia increase their demands for imports.
- d. Eastern Europe is a medium-sized importing region.
- e. The USSR, a major exporter in the 1960s is in the 1980s neither an exporter nor importer.
- f. The Asian countries with centrally planned economies, exporters in the 1963-65 period, become importers.

- g. Canada, an importer in the 1963-65 period becomes an exporter of vegetable fats and oils in the 1980s.
- h. South Africa, an exporter in the 1963-65 period becomes an importer of vegetable fats and oils in the 1980s.
- i. The developed countries who are importers are still a major market for vegetable fats and oils but the growth rate falls to as low as 1.9% annually.
- j. The increase in exports from the United States is assessed at 7.2% annually. That is, 1.2 million tons in the 1963-65 period to 3.6 million tons by 1980.

Projection Set II

Projection Set II assumes that the projected growth rate of oilseed production in the developing countries is 40% higher than that of Set I. Under this assumption, the results are as follows:

- a. The increase in oilseed production in the developing countries contributes to the reduction in the world prices for vegetable fats, oils and oil cakes to a greater extent than in the Set I.
- b. The rise in incomes in the developing countries is assumed to be greater than in Set I so that the demand for vegetable oils increases. In the developed countries, the demand for them increases only slightly.
- c. In world trade, importing countries increase their volume of imports. Exports rise only slightly in the developed countries, but rise rapidly in the developing countries.

Projection Set III

Projection Set III assumes that agricultural production and economic growth in the developing countries are at a lower level than in Set I (Agricultural production is 30% lower). Under this assumption, the results are as follows:

- a. The production of vegetable fats and oils declines almost to the production level of Set I. Demand for vegetable fats and oils is low in the developing countries.
- b. The effects of higher prices caused by the reduction in vegetable fats and oils production are to some extent offset assuming a reduction in earnings in the developing countries. World prices for vegetable fats and oils, however, are assessed higher than in Set I.

c. The level of trades among regional blocs is close to that in Set I.

Tables B-6 and B-7 indicate the results projected by Set I and Table B-8 shows the comparison between the results projected by Sets I, II and III.

The aid to the developing countries arising from US Public Law 480 is judged to have significant effects on world prices for fats and oils.¹)

With regards to earnings and expenditures related to the trade in fats and oils in the developing countries, it was shown that, under the conditions prevailing in Projection Set II, the earnings of the exporting regions are just slightly higher than under Projection Set I. This is because the growth in domestic consumption nearly offsets the increase in production. On the other hand, for the developing countries who are importers, the level of demand is greater than domestic production, and the amount of money required to purchase imports increases dramatically to exceed the revenue from exports. In Projection Set III, however, the above results is reversed.

By assuming the earnings and outlays of foreign currency by fats, oils and oil cake trade in the period 1963-65 to be \$905 million and \$92 million respectively, the overall earnings and outlays of developing countries for the three sets are as follows:

Projection Set I		Earnings Outlays	\$1,058 \$607	million "
Projection Set II	• • • • •	Earnings Outlays		
Projection Set III	• • • • •	Earnings Outlays	\$952 \$522	11 FT

1) In the case of oversupply, the supply is tightened relative to the demand by reducing the stock by providing the aid, and by the lowering of the quantity able to be supplied through ordinary transactions so that a conspicuous decline in price can be avoided.
