

## 5-1 Area C

### (1) Geology

The area is located on the west of Area B, and underlain by andesitic to basaltic lavas, volcanic breccias, tuffs, and siltstone of the Bulawayan Group. Quartz porphyry intrusive bodies are distributed in the central and southern areas. In lavas, pillow textures ranging 50 to 100 centimetres size are frequently seen, and some cases it is possible to identify its top and bottom relations from the texture. The general strike of the formations is north-northeast to south-southwest, dipping 70 to 80° to the west. In the so-called quartz porphyry intrusive bodies, primarily brecciated and sheared lava-like facies are frequently seen as well as those in Area B.

It is supposed that there is a fault extending roughly east to west in the central area, judging from the distribution pattern of the formations.

Gold deposits, which are accompanied with base metals, such as the Cuba, Cuba Syndicate, and Umniati are distributed in the northern area. However, no mineral occurrence is seen in the central and southern areas, in spite of felsic intrusive bodies are distributed there. The Cuba Deposit is in andesite, and has a record of 27 kilogrammes gold production, with the grade of 8.88 g/t Au. The deposits in the area are very small-scale as shown in the above case, and their depth of development is very shallow, up to 50 metres.

### (2) Geochemical Survey

Au, Pb and Zn were selected as path-finder elements for the survey in the area, because the area has a high potential for gold and base metals. The results of the assay showed that the contents of each element vary in different rock types. Therefore, statistics of each element were calculated for each rock type. However, specially for Au, statistics for the whole samples were applied, because its geometric means and logarithmic standard deviations for different rocks are quite close to the whole samples values; 26 ppb (0.40) for the whole, 26 ppb (0.40) for mafic volcanics, 19 ppb (0.37) for felsic volcanics, 25 ppb (0.23) for conglomerate, 23 ppb (0.42) for phyllite, 31 ppb (0.57) for mafic intrusives, and 22 ppb (0.39) for felsic intrusives.

Table 5-3-1 shows fundamental statistics of each element for

each rock type, Table 5-3-2 shows correlation coefficients between elements, Fig. 5-3-1 shows histograms and cumulative frequency distribution diagrams for Au, Cu and W, and Fig. 5-3-2 and 5-3-3 show histograms and cumulative frequency distribution diagrams for Au, Pb and Zn in different rock types.

Fairly significant positive correlation coefficients are seen between Pb and Zn in the whole samples, felsic volcanics, conglomerate, and felsic intrusives. This is a common relation in general cases.

Based on above mentioned statistical data, figures above  $\mu + \sigma$  and  $\mu + 2\sigma$  were picked up as anomalous values, and marked with small-circles and large-circles, respectively, in the geochemical anomaly maps attached in the separate case. Followings are the description of the survey results, mentioning "A" class anomaly for values above  $\mu + 2\sigma$ , and "B" class anomaly for values above  $\mu + \sigma$ .

Au; Many small-scale anomaly-zones consisting of 3 to 13 "A" class and "B" class anomalies are scattered in the area. Followings are significant ones among them.

\*In the northwestern area, a small-scale strong anomaly-zone consisting of 7 "A" class and 4 "B" class anomalies in mafic volcanics.

\*In the northeastern area, a north-south trending small-scale strong anomaly-zone consisting of 5 "A" class and 8 "B" class anomalies, and 2 parallel small-scale anomaly-zones in mafic volcanics.

Pb;\*In the central area, an irregular large-scale weak anomaly-zone consisting of 1 "A" class and 60 "B" class anomalies in mafic volcanics.

\*In the south-central area, a large-scale strong anomaly-zone consisting of 10 "A" class and 57 "B" class anomalies in mafic volcanics.

\*In the southern area, a small-scale strong anomaly-zone consisting of 6 "A" class and 9 "B" class anomalies in mafic and felsic volcanics, felsic intrusives, and surrounding 4 small-scale anomaly-zones.

-In the northeastern area, a small-scale anomaly-zone consist-

ing of 3 "A" class anomalies.

Zn; \*In the northeastern area, a wide-spread strong anomaly-zone consisting of 26 "A" class and 89 "B" class anomalies in mafic volcanics, and surrounding 8 small-scale anomaly-zones consisting of 2 to 13 "A" and "B" class anomalies mainly in mafic volcanics with minor felsic volcanics, conglomerate, and phyllite.

\*In the northwestern area, a small-scale anomaly-zone consisting of 4 "A" class and 8 "B" class anomalies in mafic volcanics.

\*In the northwestern edge of the area, 2 small-scale anomaly-zones consisting of 4 to 8 "B" class anomalies in mafic volcanics, and in the northeastern area, a small-scale anomaly-zone consisting of 2 "A" class and 6 "B" class anomalies in mafic volcanics.

Specially important anomaly zones are marked with "\*".

Regarding Au, anomaly-zones in the northwestern area and northeastern area are worth to recognize because of its strength, in spite of its small-scale, and accompanied Zn anomalies.

Regarding Pb, 2 large-scale anomaly-zones in the central and southern areas are a little deviated from Zn anomaly zones, however, accompanied by several spot-like Au anomalies. Therefore, they are worth to recognize for further study.

Regarding Zn, anomaly-zones in the northwestern and northeastern areas were mentioned in the section of Au. Other than that, a wide-spread anomaly zone in the southern area is worth to recognize because of its favourable geological environment, the contact zone between mafic volcanics and sedimentary formations, specially in the places where spot-like Au anomalies are accompanied.

### (3) Interpretation

The area is situated in a favourable geological environment, close to the Sesombi Tonalite Body and having quartz porphyry intrusive bodies in the area. Nevertheless no mineral occurrence is seen in the area except large numbers of quartz floats, trenches, and old workings in the northeastern corner of the area, a high potential for minerals is still recognized in the area.

As a result of the geochemical survey, several interesting anomaly-zones were detected. Significant anomaly-zones among them are as follows.

\* Small-scale strong Au anomaly-zones accompanied with Zn anomalies in the northwestern and northeastern areas are worth to recognize for further exploration.

\* Wide-spread Pb anomaly-zones in the central and southern areas are worth to study furthermore because of its accompanied spot-like Au anomalies.

\* A large-scale Zn anomaly-zone in the southern area is also worth to recognize for further study because of its accompanied spot-like Au anomalies.

5-4 Are D

(1) Geology

The area is located to the north of Kwekwe, and underlain by the Rhodesdale Complex in the east, the Kwekwe Ultramafic in the west, and the basaltic lavas of the Upper Greenstones in the western edge.

The gneiss of the Rhodesdale is medium to fine grained, rich in biotite and amphibole as mafic minerals, and its schistsity extends north-northeast to south-southwest, parallel to its boundary lines, with dipping of  $80^\circ$  to the west.

The Kwekwe Ultramafic is commonly subjected to serpentinization, and a silicified zone, which consists of grid-like penetration of quartz veinlets, extends north to south inside of the body. Porphyritic texture is frequently seen in other parts. Minor amounts of sulphide minerals are disseminated in some parts of the rocks associating with such silicification.

Quartz-talc schist is distributed in between the Rhodesdale and the Kwekwe in the northern area, and many quartz veins are distributed there. There is a possibility that edges of the ultramafic rock were altered to the schist after formation of sheared zones along its boundary zone.

Large numbers of quartz veins are distributed in the edge zone of the Rhodesdale in the southeastern area. No sulphide mineral is seen in the veins, and parts of them are mined for a steel mill as ferro-silicon.

(2) Geochemical Survey

Au, Ni and Cr were selected as path-finder elements for the survey in the area, because the area has a high potential for nickel-copper and gold ores. The results of the assay showed that the contents of each element vary in different rock types. Therefore, statistics of each element were calculated for each rock type. However, specially for Au, statistics for the whole samples were applied, because its geometric means and logarithmic standard deviations for different rocks are quite close to the whole samples values; 41 ppb (0.41) for the whole, 54 ppb (0.45) for mafic volcanics, 50 ppb (0.29) for felsic volcanics, 40 ppb (0.44) for banded ironstone, 34 ppb (0.43) for granitic rocks, 40 ppb (0.40) for ultramafic rocks, 40 ppb (0.46) for schist.

Table 5-4-1 shows fundamental statistics of each element for each rock type, Table 5-4-2 shows correlation coefficients between elements, Fig. 5-4-1 shows histograms and cumulative frequency distribution diagrams for Au, Ni and Cr, and Fig. 5-4-2 and 5-1-4 show histograms and cumulative frequency distribution diagrams for Ni and Cr in different rock types.

Significant positive correlation coefficients are seen between Ni and Cr throughout all the types. Same relations were experienced in the ultramafic terrain in the Shamva Area. Almost no correlation is seen between Au and Ni, and Au and Cr.

Based on above mentioned statistical data, figures above  $\mu + \sigma$  and  $\mu + 2\sigma$  were picked up as anomalous values, and marked with small-circles and large-circles, respectively, in the geochemical anomaly maps attached in the separate case. Followings are the description of the survey results, mentioning "A" class anomaly for values above  $\mu + 2\sigma$ , and "B" class anomaly for values above  $\mu + \sigma$ .

Au; Large numbers of small-scale anomaly-zones consisting of 3 "B" class anomalies to 5 "A" class and 5 "B" class anomalies are spread out in the area. Significant ones among them are as follows.,

\*In the northwestern area, a small-scale strong anomaly-zone consisting of 3 "A" class and 4 "B" class anomalies in mafic volcanics, and a small-scale strong anomaly-zone consisting of 5 "A" class and 5 "B" class anomalies mainly in ultramafic rock with small parts of banded ironstone and mafic volcanics.

\*In the central area, a small-scale anomaly-zone consisting of 2 "A" class and 4 "B" class anomalies in ultramafic rock.

Ni; \*In the northeastern to east-central area, 9 small to medium-scale weak anomaly-zones consisting of 4 to 24 "B" class anomalies in schist and ultramafic rock.

-In the northwestern area, 2 small-scale anomaly-zones consisting of 3 to 4 "B" class anomalies in ultramafic rock, banded ironstone, and mafic volcanics.

\*In the southern area, 3 small-scale anomaly-zones consisting of 3 to 13 "B" class anomalies in banded ironstone and mafic volcanics.

Cr;-In the northeastern area, 3 small to medium-scale anomaly-zones consisting of 1 "A" class and 9 "B" class anomalies to 23 "B" class anomalies in ultramafic rock.

\*In the east-central area, a large-scale weak anomaly-zone consisting of 1 "A" class and 54 "B" class anomalies in ultramafic rock.

\*In the northwestern area, a small-scale anomaly-zone consisting of 1 "A" class and 6 "B" class anomalies in mafic volcanics.

In the southern area, 3 small to medium-scale anomaly-zones consisting of 5 "B" class anomalies to 7 "A" class and 5 "B" class anomalies in ultramafic rock and banded ironstone.

Specially important anomaly-zones are marked with "\*".

Regarding Au, a small-scale anomaly-zone in the northwestern area is worth to recognize because it is accompanied with Ni and Cr anomalies. An anomaly zone in the central area is also worth to recognize because of its good concentration, in spite of its small-scale.

Regarding Ni, anomaly-zones in the northeastern to east-central area are worth to recognize for further exploration because they are accompanied with Cr anomalies and in a favourable geological environment, sitting in the edge of the ultramafic body, which is a favourable host rock for nickel-sulphide ore deposits. Several small-scale anomaly-zones in the southern area are also worth to recognize for further study because of their accompanied weak Cr anomalies and a favourable geological setting, sitting in the boundary zone between the ultramafic body and the banded ironstone.

Regarding Cr, it was already mentioned in the section of the Ni.

### (3) Interpretation

The area is situated in a favourable geological environment, in the ultramafic rock which is a favourable host rock for nickel-sulphide ore deposits such as the Hunters Road Deposit to the south of the area. Large numbers of quartz floats, trenches, and old workings are located in schist and gneiss in the eastern edge of the area. Some of those quartz veins are mined for steel mill, and for gold in other cases. No significant sulphide mineral occurrence is

seen in the ultramafic rock in this survey, however silicified zones, and large numbers of quartz veins and floats are seen in some places.

As a result of the geochemical survey, several interesting anomaly-zones were detected. Significant anomaly-zones among them are as follows.

- \* A small-scale strong Au anomaly-zone in the northwestern area is worth to recognize for further exploration because it is accompanied with Ni and Cr anomalies and situated in a favourable geological environment, near by the edge of the ultramafic body.
- \* A small-scale Au anomaly-zone in the central area is worth to study furthermore because its north to south trend is coincident to that of the geology.
- \* Large numbers of small to medium-scale Ni anomaly-zones in the northeastern to east-central area are worth to recognize for further study because of their favourable geological setting, near by the edge of the ultramafic rock, and duplicated Cr anomalies.
- \* A north-south trending Ni anomaly-zone in the southern area is worth to recognize for further study because it appears along the boundary between the ultramafic rock and the banded ironstone, and is accompanied with Cr anomalies.

## 5-5 Area E

### (1) Geology

The area is located to the northwest of Kwekwe, and underlain by mafic volcanic and pyroclastic rocks, and felsic volcanic and pyroclastic rocks of the Upper Greenstones, and sandstone and banded ironstone of the Shamvaian.

The felsic volcanic rocks have lava-like facies mixing of massive and brecciated textures. The rocks were subjected to strong alteration, producing large amounts of pale yellow pyrophyllite in the so-called Feldspar Mine area, 4 kilometres northwest of the Tiger Reef Mine, ranging 5 x 0.6 kilometres. The pyrophyllite ore is mined and shipped to a refining factory in Kwekwe. No sulphide mineral is seen in the altered zone.

In addition to a pillow texture, brecciated and turbidite textures are seen in the mafic volcanic rocks, which are accompanied with pyroclastic rocks. This phenomenon is similar to that seen in Area C. A formation of fine-grained pyroclastic rocks generally strike north-northeast to south-southwest, and dip 60° to the west.

The Shamvaian Group consists of graywacke sandstone, grit sandstone, and banded ironstone, and is distributed in a belt extending from the eastern area to the southeast area. The Tiger Reef, Unit, and Bell and Riverlea Deposits are in the Shamvaian.

The Black Prince and Gren Granite Deposits are in the Bulawayan, and situated in an extension area of a swarm of mineral deposits consisting of the Oasis, Sir Walter, Scott, and Black Prince, which are located in the northern surrounding area of the Sesombi Tonalite. It is supposed that the intensity of the mineralization is controlled by the distance from the Sesombi and the north-northeasterly extending sheared zone.

### (2) Geochemical Survey

Au, Sb and As were selected as path-finder elements for the survey in the area, because the area has a high potential mainly for gold. The results of the assay showed that the contents of each element vary in different rock types. Therefore, statistics of each element were calculated for each rock type. However, specially for Au, statistics for the whole samples were applied, because its geometric means and logarithmic standard deviations for different

rocks are quite close to the whole samples values; 37 ppb (0.37) for the whole, 37 ppb (0.38) for mafic volcanics, 38 ppb (0.36) for felsic volcanics, 26 ppb (0.17) for phyllite, 36 ppb (0.37) for banded ironstone, 39 ppb (0.39) for mafic intrusives, and 37 ppb (0.33) for felsic intrusives.

Table 5-5-1 shows fundamental statistics of each element for each rock type, Table 5-5-2 shows correlation coefficients between elements, Fig. 5-5-1 shows histograms and cumulative frequency distribution diagrams for Au, Sb and As, and Fig. 5-5-2 and 5-5-3 show histograms and cumulative frequency distribution diagrams for Sb and As in different rock types.

Regarding correlation coefficients between the elements, followings are seen; a weak positive correlation between Sb and As in the whole, a weak positive correlation between Sb and As in mafic and felsic volcanics, a fairly strong positive correlation between Sb and As in phyllite, a weak negative correlation between Au and Sb in banded ironstone, a weak negative correlation between Au and As, and a fairly strong negative correlation between Sb and As in mafic intrusives, and a weak negative correlation between Au and As, and a weak positive correlation between Sb and As in felsic intrusives. Among them, positive correlations between Sb and As are recognizable. Only one deviated from it is a strong negative correlation in mafic intrusives, however the number of samples is quite few.

Based on above mentioned statistical data, figures above  $\mu + \sigma$  and  $\mu + 2\sigma$  were picked up as anomalous values, and marked with small-circles and large-circles, respectively, in the geochemical anomaly maps attached in the separate case. Followings are the description of the survey results, mentioning "A" class anomaly for values above  $\mu + 2\sigma$ , and "B" class anomaly for values above  $\mu + \sigma$ .

Au; \*In the northeastern area, an irregular medium-scale strong anomaly-zone consisting of 12 "A" class and 11 "B" class anomalies along the contact zone between felsic and mafic volcanics.

\*In the northwestern area, a small-scale strong anomaly-zone consisting of 4 "A" class and 3 "B" class anomalies in felsic volcanics.

\*In the west-central area, a small-scale strong anomaly-zone consisting of 3 "A" class and 4 "B" class anomalies in mafic volcanics.

\*In the southwestern corner of the area, a small-scale anomaly-zone consisting of 3 "A" class and 2 "B" class anomalies in mafic volcanics.

-13 other small-scale anomaly-zones consisting of 2 "A" class anomalies to 2 "A" class and 3 "B" class anomalies scattered in the area.

Sb;-In the north-central area, an irregular wide-spread large-scale east-west extending anomaly-belt.

-In the southwestern area, 2 small scale anomaly-zones consisting of 8 to 11 "B" class anomalies in mafic volcanics.

As;\*In the central area, a wide-spread anomaly-zone which contains 6 small-scale strong anomaly-zones consisting of 2 to 8 "A" class anomalies in banded ironstone and felsic volcanics. Those in the eastern part are stronger than others.

Specially important anomaly-zones are marked with "\*".

Regarding Au, a medium-scale strong anomaly-zone in the north-eastern area is the best one found in the survey programme. Furthermore, the zone is on a boundary zone of different type of rocks, which means favourable geological environment for ores, therefore it is guaranteed for further exploration activity. Other small-scale anomaly-zones in the northwestern, west-central, and southwestern areas are worth to recognize for further study because of their strength, in spite of no other element's anomaly accompanied.

Regarding Sb and As, anomaly-zones appear in particular survey lines. It might have resulted from the analytical process, presumably preparation of sample batches and setting standards for each batch so on. Nevertheless this kind of problem exists in case of these elements, strong As anomalies in the east-central and west-central areas are worth to recognize because of their accompanied Au anomalies.

### (3) Interpretation

The area is situated in a favourable geological environment, near by the Sesombi Tonalite Body, and contains some small-scale

gold ore deposits such as the Black Princet, and some trenches and old workings, particularly in the northern area. On the other hand, a large area of alteration clay zone, mainly consisting of pyrophyllite, is seen in the central area. Judging from those evidences, it is evaluated that the area has a high potential for gold.

As a result of the geochemical survey, several interesting anomaly zones were detected. Significant anomaly zones among them are as follows.

- \* A medium-scale strong Au anomaly-zone in the northeastern area is the best target for further exploration activity, judging from its scale and strength compared with other Au anomalies found in the survey programme.
- \* Several small-scale Au anomaly-zones in the northwestern, west-central, and southwestern areas are worth to recognize for further study because of their strength, in spite of their scale.

Table 5-5-1 Fundamental Statistics of  
Each Element for Each Rock Type

Element	Rock Type	Number of Smp	Min. ppm	Max. ppm	Arith. Mean ppm	Std. Dev. ppm	Goemet. Mean ppm	Std. Dev. log

## CONCLUSIONS AND RECOMENDATION

## CHAPTER 1 CONCLUSIONS

The results of this year's programme indicated that the areas selected for the survey had a high potential for certain mineral resources, the selection of the areas was adequate for the programme, and the areas were worth further exploration.

Area A is situated in a favourable geological environment, the surrounding area of the Whitewaters Tonalite Body, which is accompanied with gold and tungsten minerals in the north. In the survey, large numbers of mineral occurrences were found on the surface, and its high potential specially for gold and tungsten was recognized. In the geochemical survey, several significant anomalies were detected. Large-scale W anomaly zones in the northeastern A-1 Block, and the northwestern and southwestern A-2 Blocks are hopeful targets for further exploration activity, specially at points in where Au anomalies are accompanied. A small-scale strong W anomaly zone in the central A-1, and compact Au anomaly zones in the southwestern A-1 are worth further study.

Area B is situated in between the Rhodesdale Complex Body and the Sesombi Tonalite Body, where is a favourable geological environment for certain minerals as well as Area A. In the survey, large numbers of mineral occurrences are located in the area, and a high potential for gold was recognized there. In the geochemical survey, a small-scale strong Au and As anomalies are duplicated in a spot in the northern area. This is the most suitable target for further exploration. Several small-scale Au and As anomaly zones appear on a large-scale weak Sb anomaly zone in the northeastern to southeastern area, and large numbers of medium to small-scale Au anomaly zones duplicated with As anomalies in the west-central to western area. They are worth further study.

Area C is situated to the east of the Sesombi Tonalite, and contains several small-scale quartz porphyry stocks. In this survey, no significant mineral occurrence was found in the area, except large numbers of quartz veins, trenches, and old workings in the north-eastern corner of the area. However an appraisal for mineral potential for the area is still high because of its favourable geological environment. In the geochemical survey, small-scale strong Au anomaly zones accompanying Zn anomalies appear in the northwestern and

northeastern areas. They are worth further exploration. A large-scale Pb anomaly zone in the west-central area and a large-scale Zn anomaly zone in the southern area are accompanied with spot-like Au anomalies. They are worth further study.

Area D is mainly underlain by the Kwekwe Ultramafic Body, which is the favourable host rock for nickel sulphide deposits. The well known Hunters Road Nickel Deposit is in the same trend of the rock to the south. In this survey, large numbers of quartz veins were seen in the eastern edge of the area, in the Rhodesdale Complex Body, however a little mineral occurrences were recognized in the Ultramafic Rock. However an appraisal for the potential of this kind of deposits is still high. In the geochemical survey, a small-scale strong Au anomaly zone in the northwestern area is accompanied with Ni and Cr anomalies, and situated in a favourable geological environment, the edge of the Ultramafic Body. This is a hopeful target for further exploration. Large numbers of medium to small-scale Ni anomaly zones in the northeastern to east-central area and a north-south elongated Ni anomaly zone in the southern area are accompanied with Cr anomalies, and situated in favourable geological environments, near by the border of the Ultramafic Body. They are also interesting targets for further study. On the other hand, A compact Au anomaly zone in the central area is coincident with the trend of the Ultramafic Body, therefore it is worth further study in spite of no anomaly of other elements accompanied.

Area E is situated to the south of the Sesombi Body, and located some of known gold occurrences. In this survey, large numbers of mineral occurrences and old workings were found specially in the northern area, and a high potential for gold is recognized. In the geochemical survey, a large-scale significant Au anomaly zone in the northeastern area, which is the best one found in the programme, is accompanied with weak Sb anomalies, and situated in a favourable geological environment, a contact zone between felsic and mafic volcanic rocks. This is one of the best targets for further exploration. Au anomaly zones in the northwestern, west-central, and southwestern areas are of small-scale but strong in spite of no anomaly of other elements accompanied. They are worth further study.

The following table shows the summary of the significant anomaly zones.

<u>Area</u>	<u>First Class</u>	<u>Second Class</u>
A	A-1 NE, large W	A-1 C, small strong W
	A-2 NW, large W	A-1 SW, medium Au
	A-2 SW, large W	
B	N, small strong Au, As	NE to SW, large weak Sb (Au, As) CW to W, medium to small Au (As)
C	NW, small strong Au (Zn)	CW, large Pb (Au)
	NE, small strong Au (Zn)	S, large Zn (Au)
D	NW, small strong Au (Zn)	NE to CE, medium to small Ni (Cr)
		S, small strong Ni (Cr)
		C, small strong Au
		NW, small strong Au
E	NE, large strong Au (Sb)	CW, small strong Au
		SW, small strong Au

## CHAPTER 2 RECOMENDATION

Based on the conclusions mentioned in the previous chapter, following surveys are recommended for the next phase programme.

1. Drilling for the most favourable anomaly zones.
2. Detail geochemical survey for some other anomaly zones.

## APPENDICES

## Appendix 1 Results of Soil Geochemical Analysis

### Abbreviation

SP-NO : Sample Number

ex. 6 - 20.

Line No.      Sampling point No.

COLOR : Soil Colour

P-YB : pale yellowish brown

D-YB : dark yellowish brown

DU-YB : dusky yellowish brown

M-YB : moderate yellowish brown

L-B : light brown

M-B : moderate brown

D-B : dark brown

M-RB : moderate reddish brown

D-RB : dark reddish brown

D-YO : dark yellowish orange

GO : grayish orange

VP-O : very pale orange

M-OP : moderate orange pink

P-B : pale brown

GB : grayish brown

DU-B : dusky brown

### (ROCK)

M-L : mafic lava

F-L : felsic lava

CGL : conglomerate

PHY : phyllite

BIF : banded iron formation

GR : granitoid

M-I : mafic intrusive

F-I : felsic intrusive

UM- : ultramafic rock  
SCH : quartz-sericite-schist

(Element)

AU : Gold 10L ; less than 10ppb  
CU : Copper  
W : Tungsten  
SB : Antimony  
AS : Arsenic  
PB : Lead  
ZN : Zinc  
NI : Nickel  
CR : Chromium
