Notes: 1) The figures in small vehicles are adjusted to be equal to the total when added for all vehicles

2) Section 5 (La Espanola-Uribe) is shown under an assumption that some traffic (35%) will divert to the new by-pass between Armenia and Zarzal after 1983. The 35% is estimated by the analysis of origin and destination survey which was conducted in February 1980. (See Chapter 3 for the detail of OD distribution.)

3) When the road between Medellin and Bogota is improved, the part of traffic is forecasted to divert to the new route from the existing road after 1983. The traffic which will divert is found 186 vehicles/day in 1980 according to the OD survey (Sm 17, Bus 14, Truck 89, and Tmula 66). They are deducted from the traffic on the sections from Melgar - Ibague - Calarca - La Espanola after 1983.

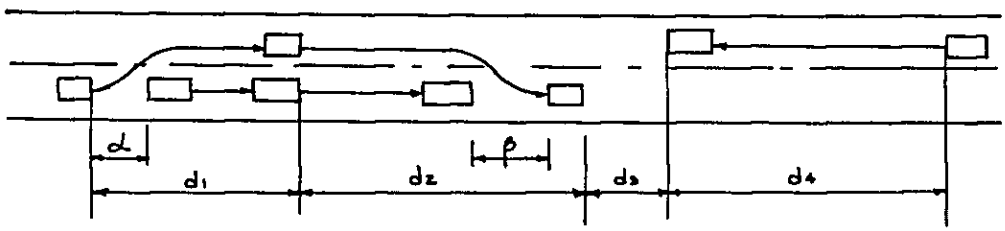
ANNEX 5

Annex 5-1 Methodology for the Estimating Capacity

1) Methodology

According to the H.C.M., level of service "C" is a zone of stable flow, and at such level of volume and density, overtaking is entirely possible whenever overpassing sight distance is provided. At level of service "D", the flow is partly unstable and the overtaking is also partially restricted. Operation at level of service "E" (when traffic volume expands) is unstable, with little independence in speed selection, i.e., overtaking becomes almost impossible.

For the project road which is a two-way road with two lanes, and without a passing lane, the concept of overtaking has been explored extensively as it is closely associated with the determination of the current level of service. The maximum density level, at which overtaking is possible, is considered to be the volume under level of service "C". As shown in Annex Fig 5-6, the total distance required for overtaking is represented by (d1 + d2 + d3 + d4.)



Annex Fig 5-6 Overtaking Distance

$$d_1 = V1 \times \frac{\alpha + a}{V_1 - Vo}$$

$$d_2 = V1 \cdot \frac{\beta + b}{V_1 - Vo}$$

$$d_4 = V \cdot \frac{\alpha + \beta + a + b}{V_1 - Vo}$$

Where: V_1 : Speed of the vehicle overtaking the slow moving vehicle.
Vo : Speed of slow moving vehicle.
a : Average length of the slow moving vehicle.
b : Average length of the fast moving vehicle.
V : Average speed of the fast and slow moving vehicles.
α, β. d_3 : Safety distances between the vehicles.

In general, the traffic volume is expressed by the following formula:

$C = V \cdot D$

Where C : Traffic volume
V : Average speed
D : Average density of vehicles.

Accordingly the volume at level of service "C" is:

$$Cc = 2.V \cdot 1 \Big/ \sum_{i=1}^{4} di \qquad \ldots\ldots\ldots\ldots\ldots \qquad (1)$$

Taking into account the adjustment factor for lane width, the actual capacity will be given by:

$C = Cc \times W$

Where W : Adjustment factor for lane width
(See Table 10.8 in H.C.M.)

2) Examples of Application

Assume a section with 7.5% grade at an altitude of 3,000m. The theoretical speeds for the fast and slow vehicles are determined by Fig 4 and Fig 5 in the document of MOPT, OP-3-21-021[1] as V_1 = 35Km/H and Vo = 10Km/H. Assuming $\alpha = \beta = d_3$ = 10m and a = 15m, b = 5m, the total of the distance in Annex Fig 5-6 will be $\sum_{i=1}^{4} di$ = 102m.

When formula (1) is applied, the following volume is arrived at by using 7% of the volume of the ADT as the peak hour ratio.

Cc = 440 Veh / H

Cc = 6286 Veh / Day

On the other hand, if the capacity is estimated directly through the methodology described by the document 1), the volume at level "C" using the same assumptions is found to be Cc = 440Veh/H and Cc = 6286Veh/Day. Although the approaches are slightly different, it is found that, in general, similar results will be obtained by both the MOPT and the study team methodologies.

---

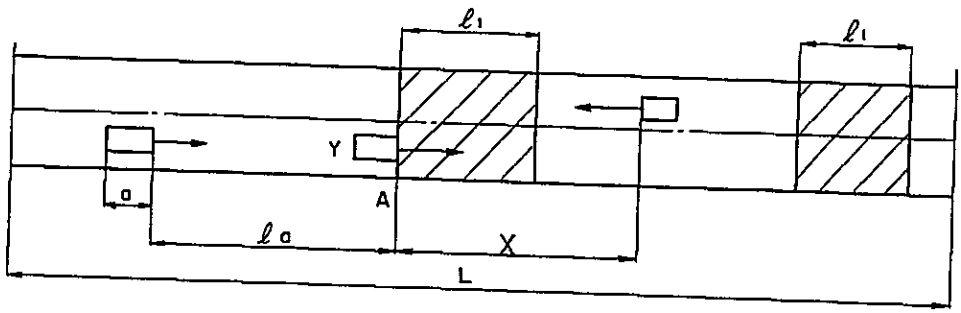
1) Louis Holguin Pardo. Conceptos de Diseno y de Nivel de Servicio y Evaluation de la Capacidad en carreteras de Montana, MOPT, OP-3-21-021, September 1980

Annex 5-2 Encounters at Sharp Curves

It is often found that where sharp curves exist, a vehicle would have to stop for several seconds to allow for the passing of another vehicle travelling in the opposite direction. This usually occurs at a curve where the road width is not adequate. Both methodologies for capacity analysis mentioned in 5-3 are based on a stable and undisturbed traffic flow, therefore these encounters are not taken into account.

When the traffic grows from year to year, the number of such encounters is certain to increase. Such encounters should be taken into account in the estimate of the capacity of the existing road.

Assume a section with several sharp curves where such encounters would occur. As illustrated in Annex Fig 5-7, it is assumed that the average headway is "1a", that the average length of a heavy vehicle is "a" and that the average speed is the same for both vehicles travelling in opposite directions. Using the figure, let us assume that a vehicle "Y" arrives at the point "A" which is the beginning of the curve "ℓ1". Whether or not this vehicle encounters another one travelling in the opposite direction depends on the length "X" which is the distance from the head of the vehicle in the opposite direction to point "A".



Annex Fig 5-7 Headway Spacing on a Curve

If $X < 2 \cdot \ell 1$ then vehicle "Y" will come into the curve and encounter the other. If $X > 2\ell 1$ the other vehicle will not be in the curve while vehicle "Y" is going through the curve section. When the average headway spacing "1a" is less than $2\ell 1$, the two vehicles will inevitably encounter each other in the curve section. The probability "P" that the vehicle "Y" will encounter the other is summarized as follows:

If $la < 2\ell i$. $\quad Pi = 1$

If $la \geq 2\ell i$ and $0 \leq X \leq 2\ell i$, $\quad Pi = \dfrac{2\ell i \cdot N}{L}$ $\qquad$ (1)

If $la > 2\ell i$ and $X > 2\ell i$, $\quad Pi = 0$

Where N is the total number of the vehicles in one direction in the section L. Pi is the probability of encounter at the curve i.

The waiting time required for the passing-by of the other vehicle is shown by the following formula.

$$ti = \frac{2a + b}{V}$$

Where V : passing speed at the curve
ti : the waiting time at the curve i
a : average vehicle length
b : additional distance required for safety

Taking into account the mutual concessions, the waiting time imposed on the said vehicle "Y" will be as follows:

$$To = \frac{1}{2} \sum_{i=1}^{n} ti.Pi \qquad \text{.....} \qquad (2)$$

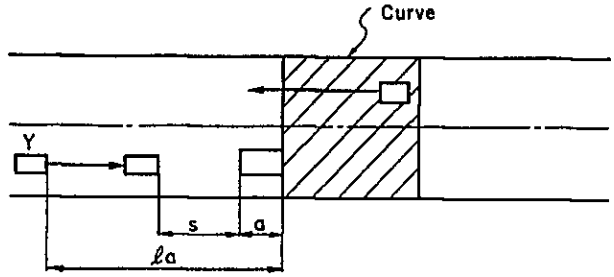
Where n : Number of curves in L
pi : Probability of encounter at the curve i
To : Waiting time of "Y" in L

In addition, the waiting time due to the encounter by the advancing vehicle ahead of vehicle "Y" will be:

$$tl = \frac{1}{2} \sum_{i=1}^{n} \left(ti.Pi - \frac{la - a - s}{Vc} Pi\right) \qquad \text{.....} \qquad (3)$$

Where s : Stopping distance of the vehicle "Y"
Vc : Speed of vehicle "Y"

The first term of equation (3) is the expected waiting time of the first vehicle ahead, and the second term indicates that the said vehicle "Y" can continue to drive for a distance (la-a-s). This is illustrated in Annex Fig 5-8.



Annex Fig 5-8 Encounters by advancing vehicles

Similarly the waiting time due to the encounter by the second and the k-th vehicles ahead fo the vehicle "Y" will be:

$$t_2 = \frac{1}{2} \sum_{i=1}^{n} \left[tiPi - 2 \frac{la - a - s}{Vc} \cdot Pi \right]$$

$$t_R = \frac{1}{2} \sum_{i=1}^{n} \left[tiPi - k \frac{la - a - s}{Vc} \cdot Pi \right]$$

If $t_R + 1 \leq 0$, there exists no disturbances by the (k + 1) the vehicle ahead of the vehicle "Y". Therefore, the total encounters of other vehicles ahead are given by the following equation:

$$Tl = \sum_{k=1}^{k} t_R = \frac{k}{2} \sum_{i=1}^{n} (ti.pi) - \frac{k\,(k+1)}{2} \cdot \frac{la - a - s}{Vc} \sum_{i=1}^{n} Pi \quad .... \quad (4)$$

The total wiating time expected for the vehicle "Y" can be given by:

$$T = To + Tl = \frac{(k+1)}{2} \sum_{i=1}^{n} (ti.pi) - \frac{k(k+1)}{2} \cdot \frac{la - a - s}{Vc} \sum_{i=1}^{n} Pi \quad .... \quad (5)$$

The reduced road capacity is given by the following formula (6):

$$C = D \cdot V = D \frac{L}{L/V_o + T} \qquad ..... \qquad (6)$$

Where D : Average density of vehicles
V : Average speed in the section L
Vo : Average speed without the curves in L

If the above formulas are applied to a road section 5Km in length involving five sharp curves, and if it is assumed that the section has the same characteristics as those in the Annex 5-1, i.e., a 7.5% grade and an altitude of 3,000m, and if the curve lengths are assumed to be 50m, 30m, 70m, 50m and 30m respectively; the volume at level C is calculated as 371 veh/H by formula (6), which indicates a reduction in capacity by 15%.

Note: 1. Km values between km 56 and km 114 are dependent on predetermined km post for construction.
2. Km values between km 114 and km 135.6 are dependent on insitu km post.
3. From km 56 to km 114 the alignments are based on the results of a survey done by MOPT and are therefore accurate.
4. From km 114 to km 135.6 the alignments are based on measurements taken from a 1/5000 scale map and are therefore not accurate.

Note:
1. Km values between km 56 and km 114 are dependent on predetermined km post for construction.
2. Km values between km 114 and km 135.6 are dependent on insitu km post.
3. From km 56 to km 114 the alignments are based on the results of a survey done by MOPT and are therefore accurate.
4. From km 114 to km 135.6 the alignments are based on measurements taken from a 1/5000 scale map and are therefore not accurate.

Annex Table- 6-2 Relationship between insitu Km Post and predetermined Km Post for construction in the Ibague - La Linea section of the existing road

Insitu Km Post	Predetermined Km Post for Construction Work	Insitu Km Post	Predetermined Km Post for Construction Work
Km 56	Km 56,000	Km 86	Km 86,057
60	59,973	87	87,038
62	61,956	88	88,027
63	62,944	89	89,011
64	63,939	92	91,940
