

## **CHAPTER 7**

### **AGRICULTURAL PRODUCTION IMPROVEMENT**

## 7. Agricultural Production Improvement

### 7.1. The Proposed Cropping Pattern

The full scale introduction of high yielding varieties is one of the most important items for setting up the future cropping pattern. The proposed cropping pattern is decided as shown in Figure 7-1-1, aiming at preventing as much as possible damages to be caused by typhoons as well as down-pour and taking into account the existing cropping pattern in the project area.

### 7.2. Yield of Paddy in the Future

The yield of paddy in the Philippines generally evidences a steady tendency of increase. In 1976, the yield was 1.721 ton/ha; while, in 1980, it increased to 2.124 ton/ha. The average annual rate of increase during the period of 5 years from 1975 to 1980 was 4.5%.

In the "Five Year Development Plan of the Philippines" (1978-1982) the yield is planned to be increased from 1.865 ton/ha in 1978 to 2.635 ton/ha in 1987, with an annual average rate of increase of 3.9% during the period.

If the aforesaid growth rate is kept unchanged over the coming decade, the production of paddy will be 1.47 times through 1.55 times as large as that one prevailing presently. However, it is perfectly feasible to expect an increase of 1.45 times through 1.50 times in the production of paddy after completion of the Mabini Agricultural Development project owing to the following reasons. The irrigation project will make possible the supply of a sufficient amount of irrigation water, which makes the capital investment for the agricultural

production effective, and increases of agricultural production and income of farmers by strengthening the agricultural extension services.

Data regarding the future yield of paddy per unit area are presented in the Table 7-1. In this project, the proposed yield per unit area is 4.58 ton/ha for the rainy season crop and 4.79 ton/ha for the dry season crop. The proposed yield can be achieved when introducing high yielding varieties in the whole project area and carrying out the paddy cultivation in accordance with the Masagana 99 Project.

### 7.3. Agricultural Technique

#### 7.3.1. Damage Caused by Blight and Insects

- 1) Major items of damages caused by diseases and insects

According to the results of observation of paddy field and of interview with farmers living in the project area, the major items of damages caused by disease and insects can be summarized as follows. The said damages seem to be more remarkable in the rainy season than in the dry season. However, during the dry season, some damages will be caused by rats.

#### Major harmful insects

- Green leaf hopper
- Rice case worm
- Rice stem boder
- Rice paddy bug

The Steps of 11 instructed in the Masagana 99 Project recommends the eradication of the green leaf hopper, because it is considered to carry the tungro virus. The selection of the variety with resistance against the green leaf hopper and against the virus carried by the said insect is the most important theme regarding the extension of the high yielding variety in the project area.

The fact that most of the farmers mentioned the name of the insects at the occasion of the interview, evidences their high concerns to damages caused by the disease and the insects.

## 2) Prevention of epidemics in plants

In course of the study, 10 farmers were interviewed in the project area. Only one farmer used no insecticide at all and all other farmers interviewed informed that they were using 1 through 5 kinds of insecticides. The financing granted to farmers through the Masagana 99 Project seems to be promoting the use of insecticides. (Part of the loan is given to the farmers in form of the coupons for procurement of insecticides and fertilizers).

The most important measures regarding prevention of epidemics is to take timely correct countermeasures. Therefore, it is indispensable to make simple observations regarding the emerge of the insects and break out of damages. The observations should be simple enough in order to make possible its execution by any farmer.

### 7.3.2. Farmers

The intention of the farmers to increase agricultural production is generally high, but the present productivity shows considerable variations in each individual case, depending on the cultivating technique. The farmers of Alaminos and Sual who have been achieving high productivity of paddy are well aware of the 16 technical steps of the M-99 Project, and have a high technical level even in the steps of the paddy nursery and paddy transplantation steps.

### 7.3.3. Extension Services

Several technical experts are working in the local office of the Ministry of Agriculture served for the four towns of the project area for the extension of agricultural techniques. However, they are too busy with jobs regarding the M-99 and other activities to extend technics into their whole territory.

As for their technical level, there are 1 or 2 highly qualified experts in prevention of damages caused by disease and insects.

The insecticide dealers offer the technical services to the farmers, but there seems to be no other remarkable activities to extend services to the farmers. With regard to the supply of guaranteed seeds by the BPI, there is no production of the seeds within the project area. Accordingly, it is indispensable to go to other areas in order to obtain the seeds.

### 7.3.4. Agricultural Experiment Stations

The extension services and the improvement of the

agricultural technics of the project area can be made under the functions of the Central Luzon Station, but there is no agricultural experimental station in the Pangasinan Province and the project area can be considered as a "desert" in terms of the agricultural technique extension.

#### 7.3.5. Agricultural Technique

Elementary education is provided at every villages or hamlets located within the project area. However, there is no institution at all for the training of the future experts, leaders and successors of the farming activities with high technics. Therefore, it is suggested that the establishment of an institution aimed at providing training course of the agricultural technics in the West Pangasinan Zone, will result a success, because the local people are showing interesting in education.

#### 7.4. Investements for Production of Paddy

In the project, investments for the production of paddy are estimated as summarized in Table 7.4.1, taking into consideration the situation prevailing presently and the future plan proposed by the Agro-Economical Survey Report of the NIA (1979). The investment amounts presented in the aforesaid table are determined by the results of local hearings and the collected data and information. With regard to the investments for the agricultural production, it is necessary to point out that the Masagana 99 Project itself presents financial problems. For example, members of M-99 can obtain low interest loans of 300 Pesons/per hectare for the application of the nitrogen fertilizers, but that amount makes possible the application of only 50 Kg/ha, and that can not be considered as sufficient.

Accordingly, establishment of an agricultural financing system is desirable in addition to the M-99.

Table 7.4.1 Input for Rice Crop Production

| Input                    | Unit          | Wet Season |           | Dry Season |
|--------------------------|---------------|------------|-----------|------------|
|                          |               | Rainfed    | Irrigated |            |
| Present:                 |               |            |           |            |
| Cultivation - Mechanical | (% Area)      | 5          | 55        | 40         |
| - Animal                 | (% Area)      | 95         | 45        | 60         |
| Seed - Transplanted      | (kg)          | 50         | 50        | 50         |
| Fertilizer - N           | (Nutrient kg) | 22         | 51        | 52         |
| - P                      | (Nutrient kg) | 15         | 28        | 28         |
| - K                      | (Nutrient kg) | 9          | 27        | 27         |
| Pesticide - Liquid       | (qt)          | .65        | 1.45      | 1.30       |
| - Granule                | (kg)          | 2.00       | 24        | 20         |
| Herbicide - Liquid       | (qt)          | .58        | .20       | .20        |
| - Granule                | (kg)          | 8.18       | 12        | 14         |

|                          |               |     |       |       |
|--------------------------|---------------|-----|-------|-------|
| Harvesting - Mechanical  | (% Area)      | 100 | 100   | 100   |
| - Manual                 | (% Area)      | -   | -     | -     |
| Cultivation - Mechanical | (% Area)      | -   | 70    | 80    |
| - Animal                 | (% Area)      | -   | 30    | 20    |
| Seed - Transplanted      | (kg)          | -   | 65    | 70    |
| Fertilizer - N           | (Nutrient kg) | -   | 70    | 80    |
| - P                      | (Nutrient kg) | -   | 30    | 30    |
| - K                      | (Nutrient kg) | -   | 0     | 0     |
| Pesticide - Liquid       | (qt)          | -   | 2.00  | 1.95  |
| - Granule                | (kg)          | -   | 33.00 | 30.00 |
| Herbicide - Liquid       | (qt)          | -   | 2.00  | 2.00  |
| - Granule                | (kg)          | -   | 16.5  | 21.00 |
| - Mechanical             | (% Area)      | -   | 85    | 90    |
| - Manual                 | (% Area)      | -   | 15    | 10    |

Future With Project:

## 7.5 Strengthening of Supporting Facilities and Services

### 7.5.1 Required Labor Force

The monthly requirements of labor forces occurring presently and expected to occur after the completion of the project are summarized in the following table.

Monthly Labor Requirement  
(1,000 man.day/month)

| Month | Present Requirement | After Completion of Project |
|-------|---------------------|-----------------------------|
| Jan.  | 7.7                 | 138.0                       |
| Feb.  | 9.1                 | 92.0                        |
| Mar.  | 3.5                 | 207.0                       |
| Apr.  | -                   | 218.5                       |
| May   | 74.5                | 69.0                        |
| June  | 322.0               | 414.0                       |
| July  | 129.5               | 126.5                       |
| Aug.  | 41.3                | 69.0                        |
| Sept. | 60.4                | 218.5                       |
| Oct.  | 51.5                | 253.0                       |
| Nov.  | 158.2               | 69.0                        |
| Dec.  | 20.3                | 425.5                       |
| Total | 878.0               | 2,300.0                     |

Presently the peak requirement of labor force occurs in June, but it may be shifted to December due to the new cropping pattern after completion of the project.

Labor requirement in December is anticipated to be 400,000 man-day/month. It is foreseen that some 20,000 farm labores will be required by assuming 20 working days per month. There is 11,500ha of the project area, while the number of farmings families living in the area is approximately 7,700 (1.5 ha of farm holding per farmers family). 15,000

workers will be available from the farming families living in the project area, by assuming that 2 workers can be available from a family.

It is still necessary to recruit 5,000 workers from sources other than the farming families living in the project area. According to data of 1970, there are 3,700 unemployed persons in the 4 towns and villages located in the project area. It may therefore be possible to absorb them in the agricultural sector.

Furthermore, there are also landless farmers living in the region and therefore it could be assumed that the labor requirements can be perfectly met within neighbouring areas of the project.

#### 7.5.2 Source of Seeds

In the Pangasinan Province, there are presently 18 seed centers which produce and distribute high yielding varieties of paddy. These seed centers have a total land area of 225ha. However, there is no seed center in the project area, and in addition, there is no seed grower of certified seed too. In view of the aforesaid circumstances, it seems to be indispensable to create a new seed center in the project area. The seed supply system of the Bureau of Plant Industry (BPI) is as follows.

|                 |  |
|-----------------|--|
| Breeder's seed  | Produced mainly at Experiment Stations |
| Registered seed | Produced by seed growers               |
| Certified seed  | Produced by seed growers               |

Seeds called "good seed" are also used as substitutes of the breeder's seeds, certified seeds and registered seeds mentioned above.

Assuming that 50% of the seed requirements of the benefited area of 11,500ha is provided by each farmer, the quantity of certified seeds required for 5,000ha of paddy field is calculated as follows.

$$5,000\text{ha} \times 0.05 \text{ ton (1 cav. per ha)} = 250 \text{ ton}$$

125ha of paddy field is required for production of seed paddy, by assuming an yield of 2 ton/ha, because rice seed requires a severe selection. The aforesaid area is equivalent to approximately 1/2 of the seed centers existing presently in the Pangasinan.

Instead of creating many small sized seed centers, it is recommendable to create four seed centers with an area of approximately 30ha in the vicinity of Alaminos, Bani, Mabini and Sual. It is necessary to construct an experiment station with an area of approximately 1.5ha in Alaminos, in order to provide the Breeder's seed.

### 7.5.3 Fertilizers and Chemicals

The quantities of fertilizers and chemicals required per unit area are presented in Table 7.4.1. The quantities of fertilizers and chemicals required in the whole project area are calculated as follows.

| Fertilizer    | <u>Requirement of Fertilizers</u> |            |       |                             |            |       |
|---------------|-----------------------------------|------------|-------|-----------------------------|------------|-------|
|               | Present Situation                 |            |       | After Completion of Project |            |       |
|               | Wet Season                        | Dry Season | Total | Wet Season                  | Dry Season | Total |
| Nitrogen (N)  | 302.3                             | 36.4       | 338.7 | 805                         | 920        | 1,725 |
| Phosphorus(P) | 194.6                             | 19.6       | 214.2 | 345                         | 345        | 690   |
| Potassium (K) | 134.1                             | 18.9       | 153.0 | -                           | -          | -     |
| Total         | 631.0                             | 74.9       | 705.9 | 1,150                       | 1,265      | 2,415 |

### Requirement of Chemicals

| Chemicals     | Present Situation |            |       | After Completion of Project |            |        |
|---------------|-------------------|------------|-------|-----------------------------|------------|--------|
|               | Wet Season        | Dry Season | Total | Wet Season                  | Dry Season | Total  |
| Insecticide   |                   |            |       |                             |            |        |
| - Liquid(q.t) | 8,835             | 910        | 9,745 | 23,000                      | 22,425     | 45,425 |
| - Powder(ton) | 60.4              | 14         | 74.4  | 379.5                       | 345        | 724.5  |
| Herbicide     |                   |            |       |                             |            |        |
| - Liquid(q.t) | 6,024             | 140        | 6,164 | -                           | -          | -      |
| - Powder(ton) | 100.6             | 9.8        | 110.4 | 189.8                       | 241.5      | 431.3  |

The required amount of fertilizers, which is presently 630 tons during the rainy season, is anticipated to be 1.265 tons, i.e., approximately 2 times as large as the present requirement. The additional fertilizer of 630 tons will be required after completion of the project. Approximately 200m<sup>2</sup> of warehouse is required in order to ensure the temporary storage of the aforesaid additional quantity of fertilizers, and furthermore, both retail sellers of fertilizers and farmers are required to make efforts to ensure an appropriate storage of fertilizers.

#### 7.5.4 Threshing and Polishing Facilities

The implementation of the present project is expected to bring the production of unhulled rice described below. In the future, the paddy production of 55,000 tons will be harvested during the dry season and expected to surpass the present paddy productions of 24,000 tons in the rainy season. As can be seen from the figures above, an additional production of 30,000 tons is expected and threshing and polishing facilities will be required as follows.

(1) Polishing Facilities

The existing polishing machines of paddy have very small processing capacities, with an average of the order of 4 tons/day. The installation of an additional quantity of 60 units of polishing machines is required, assuming that the additional quantity of paddy would be processed by machines of the same capacity as the existing facilities.

$$30,000 \text{ tons} \div 6 \text{ months} \div 20 \text{ days/month} \div 4 \text{ tons/day} \\ = 60 \text{ units}$$

The additional paddy production will be distributed through the National Food Authority (NFA). Therefore, the polishing facilities should be strengthened under the responsibility of the NFA.

(2) Threshing Facilities

The existing threshing machines have very small processing capacities, with an average of the order of 3 ton/day. Therefore, a total of 340 units of thresher is required, by assuming that the threshing of the additional paddy production of 30,000 tons is carried out within the harvesting period lasting 1.5 month, as shown below.

$$30,000 \text{ ton} \div 1.5 \text{ month} \div 20 \text{ days} \div 3 \text{ ton/day} \\ = 340 \text{ units}$$

The quantity of machines required to cope with the total production of 55,000 tons of paddy will be 600 units. This figure corresponds to approximately 1 unit of threshing machine per 12 farmers, because there are approximately 7,700 farmers living in the project area.

#### 7.5.5 Rice Warehouse

The increase of paddy production per cropping season is 30,000 ton, and this quantity will be distributed through the National Food Agency (NFA). When paddy should be packed in bags and piled up in the warehouse, the storage capacity per square meter of warehouse is of the order of 3 tons. Accordingly, the National Food Agency should construct 10,000m<sup>2</sup> of warehouse in order to store the additional quantity of paddy harvested in the project area. The construction of warehouses at 10 places is required, by assuming that each one has an area of approximately 1,000m<sup>2</sup>.

#### 7.5.6 Credit

Financing is presently provided to the farmers by the Masagana 99, through the Rural Bank and the Philippines National Bank. The upper limit of the aforesaid financing is 1,600 Pesos per ha. The total capital required to cover the whole project area is calculated as follows, by assuming that all irrigated paddy field are benefited by the credit system.

##### Capital for Financing by the Masagana 99 System

| Cropping Season | (Unit: 1,000 ₱)   |                             |
|-----------------|-------------------|-----------------------------|
|                 | Present Situation | After Completion of Project |
| Wet Season      | 2,720             | 18,400                      |
| Dry Season      | 1,120             | 18,400                      |

In the Masagana 99 System, 500 Pesos among the total financing amount is composed of fertilizers and chemicals. However, approximately 1,100 Pesos of fertilizers and chemicals are required according to data of the project. The balance of the financing provided by Masagana 99 is 600 Pesos per ha, and a new financing system is required in order to cover

the balance. The total amount of capital required in order to make possible the aforesaid additional financing is 6,900 thousands Pesos per one cropping season.

#### 7.5.7 Extension

According to the studies carried out in Alaminos, Bani, Mabini and Sual, there are 5 to 10 technicians in charge of the extension services, and the extension system seems to be good, prima facie.

However, the measures described below are required in order to increase the paddy productivity in the project area.

##### (1) Personnel

From the quantitative point of view the personnel existing presently seems to be sufficient. However, it is very important to upgrade the technical level of the experts in charge of extension services.

##### (2) Technique

Technical extension centers should be created in the project area and the extension service officers should acquire the technique required to teach every details of paddy cultivation to the farmers, by stepping in the paddy field with them. These extension service officers should join an adequate training in the technical centers described later in this report.

##### (3) Facilities and Equipment

With exception of Mabini, the extension offices are located in the town offices, but they are small in size and

the equipments in such extension offices presently provided are very poor. Therefore, a considerable reinforcement is required.

Motorcycles and scooters should be urgently provided, because means of transportation and communication are very essential for extension services.

(4) Contents of the Work

More importance should be emphasized on the actual field technology in cultivating and harvesting paddy.

(5) Extension Organization

It is estimated that there are approximately 7,000 farmers within the project area. It is recommendable to carry out the extension of the cultivation techniques by assigning one contact farmer for each 10 farmers and one extension service officer for every 70 contact farmers.

7.5.8 Research

Sophisticated research activities seem not to be appropriate in the project area. Field techniques directly necessary for the extension services and education of extension technicians are indispensable. The major items of the research activities should be in compliance with the technical needs listed below.

(1) Masagana 99

These are standard techniques for the whole national territory of the Philippines. Therefore, they should be modified in such a way to match the conditions prevailing in the

project area and appropriate technology for the project area should be adapted.

The 16 technical steps of Masagana 99 are composed of a praiseworthy technical system and therefore efforts are required in order to adapt them to the project area after necessary modification.

(2) Technical Center

It is recommendable to construct a technical center provided with the functions required to carry out the experiments listed below, in addition to the seed production and education of the extension service officers. The center should have a total area of 22ha of land provided with complete irrigation and drainage facilities, subdivided as follows.

- 15.0 ha for experiments
- 2.0 ha for training
- 5.0 ha for construction of the required facilities

(3) Technical Demands after Supply of Irrigation Water

An increasing demand for agricultural techniques is expected after completion of the project, a preparatory period of 10 years may be too short to meet the said demands. The major items of the said demands are those ones affixing the "o" mark in the list below.

- 1) Agricultural meteorological observation
- 2) Crop production
  - (1) Adaptation and screening of high yield variety
  - (2) Optimum plantation time and harvesting time
  - (3) Optimum type of cultivation, especially weeds control
  - (4) High temperature damage of rice plant in dry season
  - (5) Rice cultivation method on swampy paddy
- 3) Soil and fertilizer
  - (1) Soil management of swampy paddy
  - (2) Soil management method of every soil type
  - (3) Optimum fertilizer application for every soil type
  - (4) Application method of dry season rice crop
  - (5) Soil erosion of mountain sides
- 4) Plant protection
  - (1) Pathogenesis of insects and diseases
  - (2) Preparation of simple occurrence forecast
  - (3) Preparation of plant protection standard
- 5) Mechanization
  - (1) Land preparation technics by low power tracter
  - (2) Improvement of customary plow and harrow
  - (3) Rice planting by small machine
  - (4) Cutting by machine on wet condition
  - (5) Threshing machine and its use technics
- 6) Post harvesting
  - (1) Method of decreasing harvesting loss
  - (2) Drying method, facilities and system about after harvesting
- 7) Irrigation and drainage
  - (1) Irrigation management cooperation system
  - (2) Irrigation method in dry season
  - (3) Drainage method and its effect on swampy paddy

## **CHAPTER 8**

### **WATER REQUIREMENT**

## 8. Water Requirement

### 8.1. Proposed Cropping Pattern

The proposed cropping pattern for the project area is described in 7.1 of this report, taking into consideration the prevailing cropping pattern at present. Accordingly, the irrigation water requirement is calculated in this section, based upon the cropping pattern.

### 8.2. Water Requirement

#### 8.2.1. Reference Crop Evapotranspiration, ETo

The methods listed below are proposed and recommended by the international institutions, for the purpose of calculating the evapotranspiration of crops.

- (1) Blaney-Criddle Method
- (2) Radiation Method
- (3) Penman Method
- (4) Pan Evaporation Method, etc.

After examining the available data, it was decided to calculate the value of evapotranspiration by the Penman method, by utilizing the observation data collected at the Dagupan City. The Dagupan Observation Station is located in the vicinity of the project area and supplies sufficient data of necessary factors for the calculation of the Panman method. (Refer to Supporting Report 8.1.1.)

### 8.2.2. Crop Water Requirement, ETcrop

The crop water requirement (ETcrop) is calculated by multiplying the reference crop evapotranspiration (ETo) with the crop efficiency (Kc).

$$ET_{crop} = K_c \cdot E_{To}$$

where Kc; Crop Efficiency

As for the crop efficiency Kc of paddy, the values listed below are adopted (among the values of crop efficiency adopted by the FAO), by taking into consideration factors like local peculiarities, wind velocity and other relevant conditions.

| Period of growth    | Rainy season | Dry season |
|---------------------|--------------|------------|
| 1st month           | 1.1          | 1.1        |
| 2nd month           | 1.1          | 1.1        |
| Intermediate period | 1.05         | 1.25       |
| Last 4 weeks        | 0.95         | 1.0        |

### 8.2.3. Net Farm Requirement

The net farm requirement of paddy is calculated by adding the water requirements corresponding to the following items

- Water requirement for the land preparation and the nursery
- Supplying water for the cultivation
- Percolation

to the crop water requirement subtracting the effective rainfall.

(1) Water Requirement for Land Preparation & Nursery

The following quantities of water are required for the purpose of land preparation and nursery.

- Rainy season (ETo + P + 80)mm
- Dry season (ETo + P + 70)mm

(2) Supplying Water for Cultivation

The total depth of water required for the cultivation during the growth period of paddy is as follows.

| Upper limit | Lower limit | Rainy season |             | Dry season |             |
|-------------|-------------|--------------|-------------|------------|-------------|
| 150         | 0mm         | May 1st      | - May 25th  | Nov. 1st   | - Nov. 25th |
| 50          | 20mm        | May 26th     | - July 20th | Nov. 26th  | - Jan. 20th |
| 150         | 25mm        | July 21st    | - Oct. 7th  | Jan. 21st  | - Apr. 9th  |
|             | 0mm         | Oct. 8th     | - Oct. 31st | Apr. 10th  | - Apr. 30th |

(3) Deep Percolation

Results of the measurement of deep percolation carried out in this area indicate that it has values ranging from 0.69mm/day to 1.10mm/day, with an average of 0.88mm/day. According to the results, a design value of the order of 1mm/day seems to be appropriate in this case. However, the value of 2mm/day, mentioned also in the design standard of the NIA, is adopted because the deep percolation is expected to be increased after improvement of the paddy field, the consolidation and the drainage system.

#### (4) Effective Rainfall

The effective rainfall in case of the cultivation of paddy is calculated by means of the "Paddy Operation Study", where the water balance on the paddy field level is calculated. In the "Paddy Operation Study" method, the actual rainfall is taken as the inflow and the crop water requirement is taken as run-off and the balance between them is stored in the paddy, within the limit values of the "Supplying Water for Cultivation" mentioned in the item (2) above. In case of the surplus water, it is discharged in the drainage canals, while in case of the shortage, the required quantity of water is replenished. The value of effective rainfall can be obtained by subtracting the quantity of replenished water calculated as described above from the crop water requirement.

#### 8.2.4. Diversion Water Requirement

The diversion water requirement is calculated from the net farm requirement, taking into consideration the overall efficiency.

The following values of efficiency are taken for the calculation of the overall efficiency.

|                       | Dry season | Rainy season |
|-----------------------|------------|--------------|
| Farm waste            | 0.8        | 0.7          |
| Conveyance efficiency | 0.8        | 0.8          |
| Operation efficiency  | 0.9        | 0.9          |

Accordingly, the overall efficiency is the following values.

|                    |      |      |
|--------------------|------|------|
| Overall efficiency | 0.58 | 0.50 |
|--------------------|------|------|

As for the irrigation efficiency, the values of the overall efficiency adopted in the projects of the NIA do not exceed 50%. Observation of irrigation efficiency has been carried out in some existing irrigation projects, and the obtained data are almost same as the aforesaid value.

However, a high overall irrigation efficiency should be adopted, because irrigation water is stored in the dam and distributed over an area exceeding 10,000ha in this project. In order to achieve the high overall efficiency mentioned above, the water distribution system and the maintenance & operation system should be upgraded. In other words, the efficiency can be improved by reinforcing the training program of the employees of the NIA and farmers in charge of the maintenance and operation of the irrigation system and by equipping more complete diversion facilities (e.g. installation of turn-out gates).

The gross quantity of irrigation water per unit area is calculated as follows, as a result of the considerations above.

Values of the diversion water requirement per unit area are calculated as follows.

|      | 1967 | 1968 | 1969 | 1970 |
|------|------|------|------|------|
| Jan. | -    | 484  | 477  | 414  |
| Feb. | -    | 472  | 411  | 445  |
| Mar. | -    | 249  | 239  | 226  |
| Apr. | -    | 13   | 2    | 0    |
| May  | 82   | 41   | 82   | -    |
| June | 107  | 145  | 51   | -    |
| July | 108  | 114  | 52   | -    |
| Aug. | 0    | 0    | 0    | -    |
| Sep. | 0    | 0    | 0    | -    |
| Oct. | 0    | 0    | 0    | -    |
| Nov. | 16   | 118  | 115  | -    |
| Dec. | 449  | 460  | 416  | -    |

Unit: mm

#### 8.2.5. Maximum Water Requirement

The unit water requirement in the basic drought years are

January 1968            R = 15.61mm/day

February 1968         R = 16.28mm/day

Therefore, the maximum value of the unit water requirement occurs in February, 1968. Consequently, the maximum unit water requirement at the intake becomes

1.884 Liter/sec/ha.

Since the service area for irrigation of the project is estimated at 11,500ha (Refer to Chapter 9. Water Balance Analysis of the Reservoir), the maximum water amount is calculated as below,

$$\begin{aligned} Q_{\max} &= 1,884 \times 11,500 = 21,666 \text{ Liter/sec} \\ &= 21.666 \text{ m}^3/\text{sec}. \end{aligned}$$

## 9. Water Balance Analysis of the Reservoir

### 9.1. General

The Mabini reservoir is planned to ensure the quantity of water required for the proposed irrigable area. A series of water balance analyses regarding the quantity of water required for the project area and the quantity of water dischargeable from the reservoir with the assumed scale is carried out below. The quantity of required water for the project area is estimated in accordance with the proposed cropping pattern.

### 9.2. Water Balance of the Reservoir

The study of the water balance between the available inflow and the required quantity of water was carried out throughout the period of 3 years, by assuming that at the beginning of the study (May of 1967), the stored water level is the low water surface (LWS).

At first, the normal water surface (NWS) is set at EL63.0m, in order to determine the maximum irrigable area and the lowest intake level (Refer to 6.2 Maximum Water Surface). The study of the water balance was carried out in several cases of irrigable areas. Next step is carried out the comparative study of the results, and the results obtained in "10.3. Intake Level and Service Area" of the main report.

The river maintenance flow of the Balincaguin River at the downstream of the proposed damsite is set at 2.3 m<sup>3</sup>/s for 225 square kilometers of catchment area by using  $q = 1.0\text{m}^3/\text{s}/100\text{Km}^2$  and is kept constant flow throughout the year. (Refer to 4.6. of main report)

### 9.3. Determination of Irrigable Area and Intake Water Level

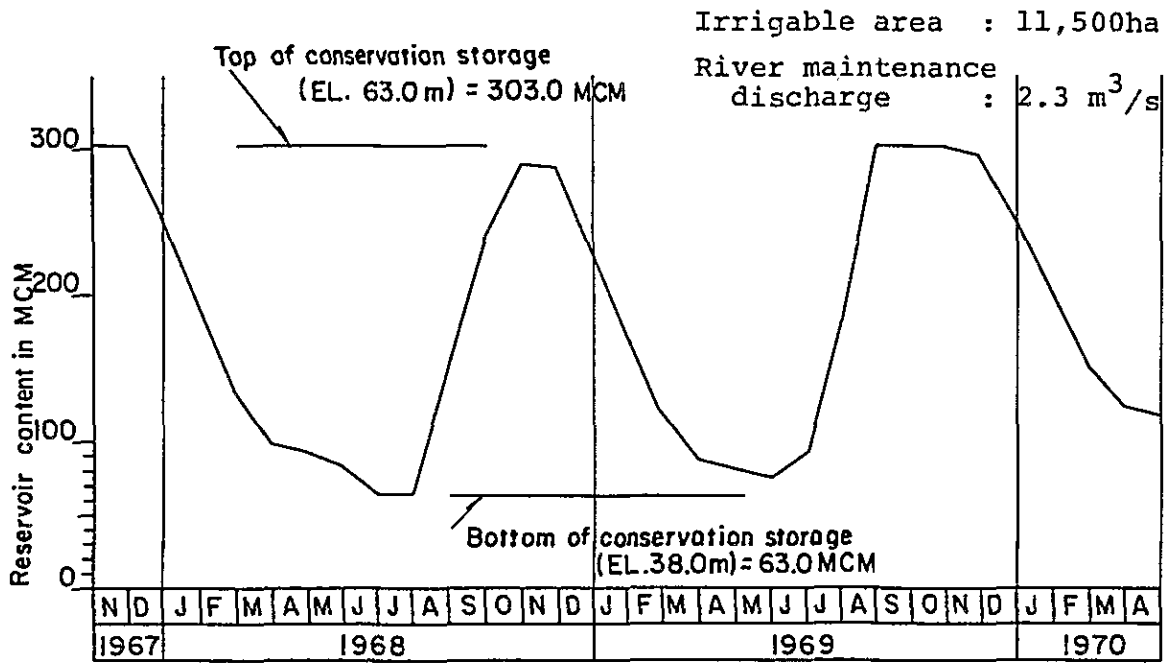

The comparison study resulted the planned irrigable area and intake level as 11,500ha and EL38.0m, respectively. The required capacity of the Mabini reservoir is estimated at 240 million cubic meters.

Accordingly, the major items of the Mabini reservoir are as follows.

|                            |                          |
|----------------------------|--------------------------|
| Normal water surface (NWS) | EL63.0m                  |
| Low water surface (LWS)    | EL39.0                   |
| Effective storage capacity | 240 million cubic meters |
| Dead water                 | 63 million cubic meters  |
| Total storage capacity     | 303 million cubic meters |

The operation of the Mabini reservoir is presented in Figure 9.2.1. According to the diagram of operation, the stored water level does not recover to the normal water surface (NWS), EL63.0m immediately after the rainy season in 1968. However, as shown in the diagram, no water shortage is made during the following dry season as well as its succeeding period. Accordingly, it is considered that the use of water during 1968 does not have any defect on the following cropping.

Fig.9.2.1 Reservoir Operation

#### 9.4. Additional Study

Request regarding the studies on the water balance in operation of the reservoir for a long term basis and on the maximum possible irrigation area was presented at the occasion of the meeting with the NIA authorities, held in 24th of February of 1982. The results of the aforesaid studies are as follows.

The period of 11 years ranging from May, 1959 to April, 1979 is selected for the said study, in view of the availability of the hydrological and meteorological data.

Results of the additional water balance analysis are presented in Figure 9.4.1, and seasonal runoff and rainfall are presented in Table 9.4.3.

## **CHAPTER 10**

### **SERVICE AREA**

## 10. Service Area

### 10.1. General

The service area is a flat and low paddy cultivation area extending over the basins of the Alaminos River and the Balincaguin River. From the administrative point of view, it extends over four municipalities (refer to "town", hereafter), namely, Alaminos, Bani, Mabini and Sual. The total arable area of the 4 towns is reported to be of the order of 19,000ha, most of which is located in existing paddy area around the town of Alaminos.

According to a land classification, a survey has already been carried out by the NIA in the area of 17,250ha which is composed of 12,146ha of arable land and of the remaining non-arable land, i.e., the dwelling land, rivers, etc. In addition to the above mentioned area, study of the project area is carried out by including the low and flat paddy area located in left bank of the Bani River and the mountainous areas. Study of additional project area resulted in 19,200ha totally and the 13,820ha of arable land.

### 10.2. Topography of the Project Area

Generally speaking, the topography of the project area presents a gentle slope (of the order of 1/300 through 1/400) from the south to the north, and therefore the topographical conditions prevailing therein are favourable for formulating an irrigation project.

The southern part of the project area is a diluvium plateau, most of which is paddy field cultivated up to the altitudes of approximately EL.40m. The northern part of the project area, particularly the vicinities of the estuary of

the Inerangan River, consists of lowland area. Paddy fields extends throughout the whole area.

There are no significant rivers in the project area except the Alaminos River and the Inerangan River. Particularly the Alaminos River which joins many tributaries should be taken into consideration at the occasion of drawing out layout of the irrigation canal systems.

### 10.3. Intake Water Level and Service Area

The relation between the area and altitude of the arable land within the project area was studied from the topographical map of 1:4,000 in scale which is still incomplete. Therefore, the topographical map of 1:50,000 in scale was used while the 1:4,000 topographical map is used complementarily. The relation between the area and altitude of arable land is presented in Figure 10.1.1 of the supporting report.

The intake water level can be determined from the altitude of the main irrigation canal, by taking into account the slope of the irrigation canal and the head losses of the intake facility to enable to supply required irrigation water to the planned irrigable area. The relation between the irrigable area and the corresponding intake water level is shown in Figure 10.2.1 of the supporting report.

The planned irrigable area of the Project was decided to be 11,500ha after water balance study utilizing effective storage capacity of the reservoir between EL.63.00m of normal water surface and EL.38.00m of low water surface (lowest intake water level). The above mentioned irrigable area can be identified within the arable land of 13,820ha.

## CHAPTER 11

### DAM

11. Dam

11.1. Determination of Dam Height

11.1.1. Crest Width

The crest width of the Mabini Dam is designed as 10m, taking into account the safety against waves, percolation and earthquakes as well as the consideration for the transportation connecting both sides of the river in the future and for the construction methods.

11.1.2. Freeboard

The free-board of the Mabini Dam is determined by formula prescribed in the dam design criteria (Ministry of Agriculture, Forestry and Fisheries of Japan). There are 2 formulae as presented below, and the height of free-board should be adopted whichever is higher

FORMULA (1) =  $H_f + h_w + h_e + 1.5$  (if  $h_w + h_e < 1.5(H_f + 3)$ )

FORMULA (2) =  $H_h + h_w + 1.5$  (if  $h_w < 0.5, H_h + 2$ )

where  $H_f$ : Normal water surface 63.00m

$H_h$ : High water surface 65.00m

$h_w$ : Height of wave due to wind 1.0m

$h_e$ : Height of wave due to earthquake 0.75m

FORMULA (1) = 66.35m

FORMULA (2) = 67.60m

In view of the results of the above calculations, the elevation of core crest is determined as 68.00m, by

adding 0.40m for allowance. The elevation of dam crest is determined as 68.50m, by adding 0.5m of core protection material. (Refer to 11.3 of Supporting Report)

## 11.2. Foundation Treatment

### (1) Main Dam

The river deposit of an approximately 30m thick has been sedimented at the proposed dam-site. The results of geological survey show that the layer is composed of sand and gravel with seepage coefficient of the order of  $1 \times 10^{-1}$  through  $10^{-2}$  cm/sec. The foundation rock consists of the basalt, has a weathered layer of 1 through 2m in thickness. Accordingly, the foundation treatment should be studied regarding two kinds of materials, the river deposit and the foundation rock. Particular importance is in the measures to deal with the sand and gravel layer of the riverbed. The cut-off trench method, the continuous cut-off wall method and the blanket method can be considered. As a result of a comprehensive study, it was decided that the cut-off trench method is the most advantageous one in view of the safety and the economy. (Refer to 11.5 Dam Type.)

### (2) Cofferdam

The amount of seepage water comes out from the riverbed sand and gravel layer under the cofferdam is estimated as the following table.

| Case | Countermeasures                               | Seepage Coefficient of Riverbed Material |         |
|------|---|--|---------|
|      |   | $1 \times 10^{-1}$ cm/sec                | Remarks |
| 1    | No Countermeasures                            | $m^3/\min$<br>323.438                    |         |
| 2    | Extension of Blanket<br>Upstream of Cofferdam | 22.990                                   |         |
| 3    | Slurry Trench                                 | 0.847                                    |         |

The amount of the above mentioned seepage through foundation of the cofferdam was calculated for the case of the probable flood of 1/20. As of now, the geological study shows that the seepage coefficient of the existing riverbed materials is the order of  $10^{-1}$  to  $10^{-2}$  cm/sec. In the rainy season, the blanket method is not sufficient to secure the safety during the construction of cut-off trench. Therefore, it is recommended that the slurry trench methods should be applied to implement safer excavation of cut-off trench for the Mabini Dam. (Refer to 11.1 of Supporting Report)

### (3) Grouting for Main Dam

The curtain grout and the blanket grout should be carried out for the foundation treatment. The curtain grout will be arranged in 3 rows, with space of 2m. The depth of the grouting is calculated by means of the Simonds's formula.

$$d = H/3 + C$$

where

d: Grouting depth

H: Water storage depth      63 - (-20) = 83m

C: Constant                      5 through 85m

The depth of the curtain grout is decided to be 15m through 35m, as a result of the calculation described above.

Four rows of blanket grout of 5m through 10m are planned at the upstream side of the curtain grout, throughout the section of 450m ranging from No. 3 through No. 12 in cross section of river at dam-site, to improve the cut-off effect and reinforce the bearing power of bedrock.

### 11.3. Seismic Coefficient

The seismic observation stations near the dam-site are located in Iba and in Dagupan. The record of previous earthquakes near the dam-site is shown in Table 11.3.1. The seismic coefficient for the stability analysis of a fill-type dam will be determined, taking into account the relation between seismic acceleration and the foundation conditions. The relationship of these are shown in Table 11.3.2. Since the proposed dam will be constructed on the foundation of the sand and gravel layer, the seismic coefficient should be 0.20 based on the recorded maximum seismic acceleration.

Table 11.3.1 Earthquake Recorders

#### 11.4. Embankment Materials

##### (1) Outline of the embankment materials

The embankment materials will be obtained in accordance with the plan described below, taking the topographical and geological conditions of the dam-site into account.

Core material - The reddish brown soil, which originated from the weathered basalt, and the dark brown soil, which consists of the alluvium, can be used as the core materials. The borrow area is shown in Figure 11.3.1. The quantity of the core material existing therein is more than 720,000 m<sup>3</sup>, which is sufficient in volume.

Transition material - The weathered basalt and the limestone can be utilized as transition materials. It is expected that the transition material will be composed mostly of the excavated material from the spillway, which is estimated at approximately 3,000,000 m<sup>3</sup> of material.

Filter material - Large amount of river deposit found at the damsite can be utilized as filter material, after screening and washing of river deposit.

Rockfill material - The fresh basalt will be used as the rockfill material. The quarry site for the rockfill is shown in Figure 11.3.1. It is estimated at about 5,000,000 m<sup>3</sup> of the rock. However, further survey is required prior to the implementation of the project because drilling survey and other detailed studies have not been carried out.

It is recommended that the borrow area should be limited within reservoir area from environmental stand of view.

(2) Results of the Survey of Embankment Materials

Five test pits were dugged, to make sure the available materials for embankment. A total of 11 samples were collected from the test pits and a soil test was carried out. Mechanical tests of rock materials were carried out by the sample taken from the boring cores of dam-site. Test results of embankment material are shown in Figure 11.3.2..

a) Core material

The reddish brown soil, the dark brown soil and the light brown soil are examined as core materials.

Reddish brown soil - This material consists of the residual soil and the weathered basalt. The samples are obtained from ATP.1. This soil is also found very often at the right bank of the downstream. This material is classified as MH in the unified soil classification.

Dark brown soil - This is the alluvium composing the paddy field located at the upstream side of the dam axis. Samples of this material are obtained from ATP.2. This layer partially contains cobbles, but this material is classified as CL and CH.

Light brown soil - This is the residual soil found in the limestone zones. Samples of this materials are collected from ATP.5 of the left bank of the downstream.

It is classified as SM.

All materials are of less seepage coefficients, of the order of  $\alpha \times 10^{-6}$  through  $10^{-8}$  cm/sec, presenting, therefore, sufficient impermeability. The natural moisture content of almost all materials exceeds by 10% over the optimum moisture content. It is considered that this is caused by the sampling in the rainy season, but the extent of the influence is unknown. The core materials were examined by triaxial compression test of specimens with a density equivalent to 95% of the maximum dry density and having wet side moisture content. The results of the soil tests are presented in Table 11.3.1.

b) Transition material

Samples of the weathered basalt was obtained from the test pit APT.4. This material is classified as SM and SW-SM according to the laboratory tests. The seepage coefficient is of the order of  $10^{-5}$  cm/sec, because its particles are fragile. The specimen with a density equivalent to 95% of the maximum dry density were examined by triaxial compression test. The results of soil tests are presented in Table 11.3.1.

c) Rockfill materials

Rockfill materials were examined by compressive strength test, the specific gravity test and the water absorption test, by using samples taken from boring cores. The test results are presented in Table 11.3.2. The results of additional tests carried out in Japan are presented in Table 11.3.3. The results of such tests show low strength of both the limestone and the basalt. The rockfill material for the riprap should be selected from better quality rock material excavated from the spillway and quarry site.

d) River deposit

The river deposit can be used as the filter. The test samples are obtained from the test pit ATP.3. It was not possible to estimate the density of the samples in the field due to the insufficient test equipments. In the laboratory, a triaxial compression tests is performed on the material passing No. 4 sieve. The density of the specimens is made as low as possible. (Dry density =  $1,497 \text{ g/cm}^3$ ), being obtained a cohesion  $C = 0.65 \text{ kg/cm}^2$  and an angle of internal friction  $\phi = 26^\circ 20'$ .

(3) Design parameters

The design data are selected from the results of the tests of the embankment materials. The stability analysis is carried out by the effective stress analysis, but it is not possible to obtain the effective stress, because the triaxial compression test equipment furnished by the NIA is not equipped with pore pressure measurement device. Accordingly, the design strength is determined based upon the total-stress parameter. The selected design parameters are presented in Table 11.4.4.

Table 11.4.4 DESIGN PARAMETER FOR EMBANKMENT

| Item          |                                  | Density                    |                                     | Strength                |                                  |

## 11.5 Dam Type

The concrete type is not suitable for the Mabini Dam, in view of the topographical and geological conditions. The earth-fill dam is also excluded because of the availability of the earth material for embankment. There are two types of rock-fill dam, namely, the central core type and the inclined core type. In the case of the Mabini Dam, results of the stability calculations suggest that the inclined core type is not appropriate, due to the small shearing strength of the core material. (Refer to Supporting Report 11.3.1.)

As a result of the above considerations, the central core type rock-fill dam is selected for the Mabini Dam. Another problem of the Mabini dam is the foundation treatment of the riverbed which affects the cross section of the dam. Therefore, a comprehensive study including the foundation treatment of the riverbed is carried out herein. The combinations of the various treatment and dam type for alternatives are as follows.

|        | Treatment of River Deposit | Dam Type               |
|--------|----------------------------|------------------------|
| Type-A | Cut-off Trench             | Central Core, Rockfill |
| Type-B | Cut-off Wall               | Central Core, Rockfill |
| Type-C | Soletanche Grouting        | Central Core, Rockfill |

The standard cross sections of the 3 types of combination are presented in Figure 11.5.1. After a comparative study of the aforesaid 3 alternatives, it is decided to adopt the central core type, TYPE-A, which carries out the excavation down to the foundation bedrock, in view of the following reasons. (Refer to Figure 11.5.3.)

1) The Construction Cost is Economical

The alternative of TYPE-A requires a construction cost approximately 150 million Pesos (US\$150 million) cheaper than the alternatives of TYPE-B and TYPE-C. (Refer to Supporting Report 11.3.2.)

2) This Type is Safer in Terms of Permeability

The continuous cut-off wall has possibility to present water leakage from concrete joints and water leakage from the boundary of the continuous cut-off wall and the core at the occasion of earthquakes, etc.

3) This is the Type Offering the Safety for Subsidence of Riverbed Material

Subsidence of river deposit is anticipated after completion of dam embankment. In the case of the continuous cut-off wall, there is a risk of destruction of the continuous wall, because a negative friction force is caused by the differential subsidence between cut-off wall and the riverbed sand and gravel layer, which are loaded by the dam body weight (approximately  $120 \text{ t/m}^2$ ). However, the differences of subsidence amounts are minor, because the dam of the TYPE-A alternative is made from the same material.

4) This is Safer Type in Case of Earthquakes

In the case of continuous wall, the characteristics frequency of the wall is different from the characteristic frequency of the foundation bedrock at the occasion of earthquakes. Therefore, cracks will be developed at the boundary between the continuous wall and the bedrock, being prone to cause water leakage and piping.

5) There are many Cases of this type in Philippines

The central core type rock-fill dams are prevailing in the Philippines. In other words, the Philippines Engineering Force has much experience in the construction of such type of dam.

6) This Alternative Makes Possible to Check by Direct Observation of the Conditions of the Foundation Rock

In this method, it is possible to check the conditions of the foundation rock by direct observation because the excavation of the cut-off trench reaches the foundation bed-rock. It is also possible to undertake grouting activities with high reliability.

## 11.6. Design of Dam Embankment

### 11.6.1. Stability Analysis of Dam Embankment

The stability analysis of the Mabini Dam is carried out by "The Slip Circle Method" in the 6 cases of which conditions are listed in the table below. (Refer to Fig. 11.6.1).

| Condition                    | Water Level of the Reservoir            | Horizontal Seismic Coefficient | Upstream | Downstream |
|------------------------------|---|--------------------------------|----------|------------|
| After Completion             | Normal Water Surface 63.00 <sup>m</sup> | 0                              | Case 1   | Case 2     |
| After Completion             | Normal Water Surface 63.00              | 0.2                            | Case 3   | Case 4     |
| After Completion             | Intermedaite Water Level 38.00          | 0.2                            | Case 5   | -          |
| Immediately after Completion | Empty -                                 | 0.1                            | Case 6   |            |

The minimum safety factor is upstream SF = 1.23 and downstream SF = 1.21 at the occasion of normal water surface. The results of the safety analysis in the various cases are as follows.

|        | Water Level | Seismic Coefficient | Upstream or Downstream | Minimum Safty Factor |
|--------|-------------|---------------------|------------------------|----------------------|
| Case 1 | N.W.S       | 0                   | Up                     | 2.77                 |
| Case 2 | N.W.S       | 0                   | Down                   | 1.93                 |
| Case 3 | N.W.S       | 0.2                 | Up                     | 1.23                 |
| Case 4 | N.W.S       | 0.2                 | Down                   | 1.21                 |
| Case 5 | L.W.S       | 0.2                 | Up                     | 1.41                 |
| Case 6 | Empty       | 0.1                 | Up                     | -                    |

The upstream slope of the Mabini Dam is determined as 1:3.0 and the downstream slope is determined as 1:2.2, as a result of the stability analysis.

#### 11.6.2. Study of the Seepage of Dam Embankment

The diagram of the seepage flow drawn out when the normal water surface (EL.63m) of the Mabini Dam is shown in Figure 11.6.2. The downstream water level is assumed to be EL12.00m. The water leakage from the dam body is calculated as follows.

Water leakage per day

$$Q_{\text{day}} = 2.3664 \text{ l/sec} \times 86,400 \text{ sec} = 204.5 \text{ m}^3/\text{day}$$

Seepage loss from reservoir is estimated at 0.05% of total reservoir capacity. (Refer to 9.2.(4) of Supporting report)

$$303,000,000 \times 0.0005 = 151,500\text{m}^3 > 240.5\text{m}^3/\text{day}$$

The upstream slope of the Mabini Dam is determined as 1:3.0 and the downstream slope is determined as 1:2.2, as a result of the stability analysis.

#### 11.6.2. Study of the Seepage of Dam Embankment

The diagram of the seepage flow drawn out when the normal water surface (EL.63) of the Mabini Dam is shown in Figure 11.6.2. The downstream water level is assumed to be EL12.00m. The water leakage from the dam body is calculated as follows.

Water leakage per day

$$Q_{\text{day}} = 2.3664 \text{ l/sec} \times 86,400 \text{ sec} = 204.5 \text{ m}^3/\text{day}$$

Seepage loss from reservoir is estimated at 0.05% of total reservoir capacity. (Refer to 9.2.(4) of Supporting report)

$$303,000,000 \times 0.0005 = 151,500\text{m}^3 > 240.5\text{m}^3/\text{day}$$

11.7. Land Acquisition

It is expected that the land for the dam-site and the reservoir area should be acquired prior to the commencement of dam construction work and that the trees should be cut before storing water.

The number of families who would require resettlement is 85.

Currently, there is no road in the upstream of the proposed dam-site. However, it is necessary to construct a new road around the reservoir of 2.00m in width for pedestrians as a service for residents in the upstream area.

**CHAPTER 12**  
**SPILLWAY STRUCTURE**

[The page contains extremely faint and illegible text, likely bleed-through from the reverse side of the document. The text is scattered across the page and is not readable.]

## 12. SPILLWAY STRUCTURE

12.1. Location and Route

It is decided to locate the spillway structure at the right bank side, after having taken consideration as listed below.

- (1) The spillway with straight configuration, which is more advantageous from the hydraulic point of view, can be constructed at the right bank side.
- (2) The confluence to the original river is more smooth at the right bank side.
- (3) The geological survey disclosed a low velocity zone at the left bank side. The construction of any important structure like spillway at left bank is not recommendable.

## 12.2. Flood Tracing

The flood control effect of the reservoir results from the balance between the inflow and the outflow. The relation between the stored water, the inflow and the outflow is given by the following expression, by taking a time interval  $\Delta t$ .

$$S = Q_i \cdot \Delta t - Q_o \cdot \Delta t$$

where:

- S : The quantity of water stored during the interval of time  $\Delta t$ .
- $Q_i$ : The average inflow during the interval of time  $\Delta t$ .
- $Q_o$ : The average outflow during the interval of time  $\Delta t$ .

The hydrograph of the flood obtained from the Probable Maximum Precipitation is used for the inflow (Refer to 4.4.) The variation in the discharge curve of the flood spillway are influenced not only by the size and configuration of the spillway, but also by the method of adjustment of the discharge. The Flood Tracing calculation is carried out for the gated spillway and for the side-channel spillway.

- (1) In case of the gated spillway
  - a. The design flood is assumed to start when the reservoir water is at the normal water surface.
  - b. The gate is assumed to be operated in such a way to keep always the normal water surface.
- (2) In case of side-channel spillway
  - a. The length of the crest of overflow is limited to be 180 m, due to the topographical conditions.
  - b. The side-channel spillway will be operated without man power.

The results of the flood discharge calculation regarding the gated spillway and the side-channel spillway, which was carried out by the above conditions are referred to Figure 12-1-1 and Figure 12-1-2 of Supporting Report. The results of calculation are presented in the table below.

|                            | Gated Spillway             | Side-Channel Spillway      |
|----------------------------|----------------------------|----------------------------|
| Maximum Rate of Outflow    | 3,100 m <sup>3</sup> /sec  | 3,630 m <sup>3</sup> /sec  |
| H.W.S                      | EL. 65.00 m                | EL. 65.00 m                |
| N.W.S                      | EL. 63.00 m                | EL. 60.30 m                |
| Effective Storage Capacity | 240,000,000 m <sup>3</sup> | 201,000,000 m <sup>3</sup> |
| Capacity at N.W.S          | 303,000,000 m <sup>3</sup> | 264,000,000 m <sup>3</sup> |
| Capacity at L.W.S          | 63,000,000 m <sup>3</sup>  | 63,000,000 m <sup>3</sup>  |

### 12.3. Selection of the Type of the Spillway

In the gated spillway, it is possible to use a design flood equivalent to 78% (3,100 m<sup>3</sup>/s) of the inflow due to the effect of surcharge, but in the side-channel spillway (ungated type spillway), it is required to use 91% (3,630 m<sup>3</sup>/s) of the inflow. In other words, the peak flood can be reduced at 3,100 m<sup>3</sup>/s from 4,000 m<sup>3</sup>/s of PMP because of the surcharge of 2 m by using gated spillway.

The highest possible water level of the proposed reservoir will be less than EL. 65.00 m in view of the topographical and geological conditions. After reducing 2 m of surcharge, normal water surface will be resulted at NWS EL.63.00 m and the effective storage capacity of 240,000,000 m<sup>3</sup> in case of a gated type spillway. However, in case of ungated type spillway, the crest elevation becomes EL.60.30 m and the effective storage capacity 201,000,000 m<sup>3</sup> even in case of adopting the maximum crest length (L = 180 m) allowed by the topographical conditions. Therefore, the gated type spillway is advantageous from the hydrological point of view, compared with the ungated type spillway. Also the comparison of the

construction costs evidences the advantage of the gated type spillway. (Refer to 12-2 of supporting report)

From the future operation and maintenance point of view, the gated spillway is disadvantageous compared with the side-channel spillway (ungated type spillway). However, spillways of dams existing in Philippines are mostly of gated type.

Therefore it is decided to adopt the gated spillway. The design flood discharge is estimated at 3,100 m<sup>3</sup>/sec, the design level of the high water surface (HWS) at EL.65.00 m and the normal water surface (NWS) at EL.63.00 m. For this purpose, a gate type which can be possible to overflow will be adopted in this spillway in case of emergency.

#### 12.4. Structural design

##### 12.4.1. Alignment

The chute of the spillway and the energy dissipator are designed with straight line in formation. The centerline of the spillway crosses the dam with an angle of about 63°.

##### 12.4.2. Determination of the scale of the gate

The study for the determination of the scale of the gates is carried out to discharge a designed flood of  $Q = 3,100$  m<sup>3</sup>/s, a high water surface of EL.65.00 m and cases of 4 gates, 3 gates and 2 gates, respectively (Refer to 12.3.2 of Supporting Report). All cases present no problem from the hydrological point of view, but the number of gates is determined as 4 from the points of view of easier operation of the gates and economical advantages.

Accordingly, 4 gates with 9.50 m width x 10.5 m height will be installed in the spillway. The total width of the gate structure will be about 50.0 m including three piers of 3 m wide.

#### 12.4.3. Chute portion and stilling basin

The width of the chute is about 50 m, same as gate structure. Chute portion is divided into two, namely steep slope and gentle slope in conforming to the topographical conditions, and the gradients in each case are 1:2.5 and 1:20, respectively.

To disperse the energy of flood, the auxiliary dam type is adopted in this spillway, in view of its advantages regarding hydraulic safety, adequacy to the topographical and geological conditions of the related area, etc..

#### 12.4.4. Warning system for flood discharge

In case of flood, the gates of spillway structure must be open step by step to discharge the flood from reservoir. However, there is a possibility to give calamities to the villagers and fishermen working in the river downstream. Therefore, facilities of warning system should be necessary to inform the villagers living downstream of increasing the river water amount before opening the gates of spillway.

### The Major Items of the Spillway

|                    |   |   |
|--------------------|---|---|
| Location           | : | Right abutment of the dam                     |
| Type               | : | Chute type with gates                         |
| Designed Discharge | : | 3,100 m <sup>3</sup> /sec.                    |
| Water Head         | : | 12.0 m (designed discharge)                   |
| Gate Size          | : | H = 10.5 m, B = 9.5 m                         |
| Gate Number        | : | Four units                                    |
| Width of Chute Way | : | 47.0 m  |
| Slope of Chute Way | : | 1:20 upstream and<br>1:2.5 downstream portion |

### Elevation

|                            |   |        |
|----------------------------|---|--------|
| High Water Surface         | : | 65.0 m |
| Normal Water Surface       | : | 63.0 m |
| Top of the Weir Crest      | : | 53.0 m |
| Bottom of Approach Channel | : | 48.0 m |
| Bottom of Stilling Basin   | : | 7.4 m  |
| Crest of Auxiliary Dam     | : | 14.1 m |
| River Bed                  | : | 12.0 m |

### Velocity of Flow through Spillway Structure

|                                |   |             |
|--------------------------------|---|-------------|
| Approach Channel               | : | 3.88 m/sec  |
| Crest                          | : | 7.37 m/sec  |
| Max. Velocity of Chute Portion | : | 28.34 m/sec |

### 13. Diversion Works

#### 13.1. Selection of Diversion System

There are two alternatives in temporary diversion of river when construction of dams, namely, a diversion tunnel system and the open channel system passing through a dam body. The open channel system is adopted often in cases of a concrete dam and a combined dam constructed in wide riverbed, where about 1/2 of the width of riverbed is sufficient to handle the design flood discharge during construction period. The tunnel system, which can be possible to construct the dam with more safety and reliability, is adopted in this project, in view of the following reasons.

- The rockfill type dam is selected for this project
- The amount of the design flood discharge amount is too large compared with the river width
- The foundation treatment in the riverbed requires a long period of time, etc.

#### 13.2. Diversion Flood Discharge

The value of the design discharge to be adopted in the diversion work should be determined by taking into consideration the type of dam, the characteristics of the flood, the flood frequency during the construction period and the anticipated damages in case of overflow. Generally speaking, the 10-20 year probable discharge is adopted in case of fill-dams. The adoption of the 20-year probability seems to be appropriate in the case of the Mabini Dam, because the design

standard of the Philippines is 1/20-1/50, in addition to the adoption of the open-cut method for the foundation treatment. Accordingly, the diversion flood discharge is estimated to be 1,500 m<sup>3</sup>/sec (Refer to 4.4 Hydrology of the Main Report).

### 13.3. Selection of Route

It is recommendable to locate a diversion tunnel at the right bank side of the river, because the tunnel length results approximately 150 m shorter than that of the left bank alternative. The right bank side is also advantageous to be able to install the intake facility inside of the diversion tunnel, because the intake facility should be at right bank side where project area to be irrigated spreads.

### 13.4. Tunnel and Cofferdam

#### 13.4.1. Cross section of the diversion tunnel and elevation of the cofferdam

The elevation of the cofferdam and the diameter of the diversion tunnel are mutually related. Accordingly, the combination of the size of the diversion tunnel and the elevation of the cofferdam is determined by carrying out the economic comparison. As can be seen in Table 13.1.1 and Table 13.1.2. of supporting report, the tunnel diameter of 8.5 m and the cofferdam elevation at EL.36.00 m is the most advantageous combination.

#### 13.4.2 Number of tunnels

In case of using only one tunnel, an extremely large one, having a 2R type standard horseshoe type cross section with

12.2 m diameter and excavation cross section of 130 m<sup>2</sup> is required in order to discharge the flood flow of Q<sub>max</sub> = 1500 m<sup>3</sup>/s. (Refer to Table 13.2.1 of supporting report). It is therefore decided to provide two diversion tunnels by taking into consideration the amount of the diversion discharge, the easy construction of the tunnel plug work, etc. One of the diversion tunnels will be used intake facility later on.

#### 13.4.3 Combination of tunnel diameters

Economical comparison is carried out for 5 different combinations. As a result, the combination of 2 tunnels with standard horseshoe type cross section with 2R = 8.5 m is adopted (Table 13.2.2 of supporting report).

#### 13.5. Major Dimension of the Diversion Work

Major dimension of the diversion work is summarized as followings:

##### Diversion Tunnels

|                 |  |
|-----------------|--|
| Location        | : Right abutment of the dam                    |
| Cross Section   | : Standard horseshoe type                      |
| Tunnel Number   | : 2-units                                      |
| Tunnel Diameter | : D = 8.5 m                                    |
| Slope           | : 1/350, 1/125                                 |
| Tunnel Length   | : 750 m, 790 m                                 |
| Velocity        | : 12.5 m/s (discharge: 1500 m <sup>3</sup> /s) |

Elevation of Tunnel Entrance : EL 13.20 m, EL 17.32 m

Elevation of Cofferdam Crest: EL 36.00 m

**CHAPTER 14**  
**INTAKE FACILITY**

## 14. Intake Facility

### 14.1. Location

A maximum quantity of 25.31 m<sup>3</sup>/s (21.666 m<sup>3</sup>/s for irrigation + 3.644 m<sup>3</sup>/s for river maintenance flow in maximum) of water is taken from the stored water between a normal water surface of HWS = 63.00 m and a low water surface of LWS = 38.00. (Refer to 9.3) The intake facility should be located at the right bank side, because all service area are located at the right bank side.

Two standard horseshoe type diversion tunnels with 8.5 m diameter are constructed at the right bank side in this project. One of the said diversion tunnels will be used as intake facility.

### 14.2. Intake Type and Structure

#### 14.2.1. Selection of the type

There are various possible types of intake facilities, namely, tower type, inclined tower type, the shaft type, etc. (Refer to Figure 14.2.1). The shaft type is adopted as a result of the comparison study of the possible alternatives (Table 14.1.1 of supporting report), in view of the following study.

#### Tower type

The maintenance and inspection of the whole intake facility is easy in this type of structure, because an emergency gate and control gates are provided at the entrance of the intake tower.

However, this type of structure is appropriate for dams with shallow reservoir depth, or steep sloped abutment requiring a short connecting bridge and offering satisfactory conditions of bedrock. In view of the foregoing, this alternative seems to be not economical, because about 150 m long bridge with 5 through 6 spans will be required in this case.

#### Inclined tower type

This type of structure is applicable when the slope is steeper than 1:1.2. (This type of intake structure should have such slope as the gate comes down by the gravity). This might be one of the cheapest alternatives if the topography and geology is permitted.. However, this alternative is not recommendable due to the gentle slope (1:3.5) of the abutment where structure is located.

#### Shaft type

This type can be adopted, if the intake of the slope tower is not preferable. This is the standard type of pressure tunnel according to the "Design of Small Dams", published by the Bureau of Reclamation of the United States. However this type presents disadvantage, as it is almost impossible to inspect the tunnel portion upstream side of the emergency gate after completion. Therefore, it is required to locate the shaft as close as possible to the reservoir.

The economical comparison of these alternatives indicates that the construction cost of the tower type structure is  $1175 \times 10^3$  US\$, while the cost of the shaft type structure is  $328 \times 10^3$  US\$, i.e., the latter one costs 1/3.5 times lower than the former one. (Refer to Tables 14.1.1 and 14.1.2 of supporting report).

#### 14.2.2. Structure

The intake structure will be a 10 m wide x 10 m high concrete structure with a steel screen and installed at the entrance of one diversion tunnel No.1. An emergency gate will be provided at upstream position of the diversion tunnel. The intake facility will use the existing diversion tunnel with the concrete plug at the middle reaches of the tunnel (length of plug portion is approximately 40 m), while at the downstream side of the plug, steel pipes will be installed.

Fig.14.2.1 Type of Intake Works

**CHAPTER 15**  
**IRRIGATION PROJECT**

## 15. Irrigation Component

### 15.1. Alternatives of the Driving Channel

The driving channel of an open canal is constructed along contour lines. A straight line position between the point A and B of the length of 2.4 Km was studied for an alternative. (Section A-B, Refer to Figure 15.1.1) However, it was decided to adopt the open canal for the driving channel, because of the following reasons.

- (a) The ground of the tunnel route and its vicinities is composed of the limestone layer, which presents risks to encounter spring water and caves. This is not appropriate for the construction of tunnels.
- (b) The open channel is more advantageous from the economic point of view. (Refer to Supporting Report, Table 15.1.1).

### 15.2. Driving Channel

#### 15.2.1. Tunnel of the driving channel

The altitude of the ground located behind the intake is of approximately EL.100 m, while the elevation of the intake is EL.38.00 m. Therefore, the upstream portion of the driving channel should be a tunnel. As mentioned before, two diversion tunnels will be excavated at the right side abutment. Accordingly, the most advantageous alternative is to use the aforesaid diversion tunnel as driving channel. Results of the study indicate that the use of the diversion tunnel for the irrigation and the hydroelectric power generation do not present problems. Therefore, it was decided to utilize one of the two diversion tunnels for driving channel.

### 15.2.2. Open section of the driving channel

#### (1) Selection of route

The open driving channel will be located along the topographical contour lines.

#### (2) Type of channel

The driving channel is required to pass a large discharge of the order of  $Q = 21.666 \text{ m}^3/\text{sec}$ , and there is a possibility of the leakage loss from the channel if it is unlined, because its foundation contains porous limestone. Therefore, the driving channel should be lined. There are two possible alternatives regarding the type of a lining channel, i.e., flume type and grouted masonry type. The grouted masonry type channel is adopted in this channel, in view of its economic advantages.

#### (3) Standard cross section of the channel

The driving channel will be a three face lined type one, and the road for the maintenance and operation purposes ( $B = 6.0 \text{ m}$ , T-14t) will be constructed along the channel. The standard cross section stipulated in the design standards of the NIA will be adopted for the driving channel. The hydraulic specifications and standard cross section of the driving channel are as follows.

|                           |   |                                     |
|---------------------------|---|-------------------------------------|
| Discharge                 | : | $Q = 21.666 \text{ m}^3/\text{sec}$ |
| Type of channel           | : | Grouted masonry type                |
| Applicable formula        | : | Manning's formula                   |
| Coefficient of roughness: |   | $n = 0.025$                         |

The standard cross section of the driving channel is shown in Figure 15.2.1 of the Supporting Report.

### 15.3. Main Canals and Lateral Canals

#### 15.3.1. Main canal Mo (Mabini Diversion Works - Diversion Works devided into East and West main canal Wo/Eo)

$$Q = 20.536 \text{ m}^3/\text{sec} \quad L = 3.0 \text{ km}$$

The main canal will be an open canal type one. Some excavation will be necessary because the ground elevation is 10 m to 15 m higher than that of the bottom of the canal. (Refer to Figure 15.3.1. of the Supporting Report).

#### 15.3.2. East and west main canal and lateral canal

##### (1) Routes of the canal

The East and west main canal will extend towards the east and west direction at the diversion point Wo/Eo. As can be seen from the discharge distribution diagram, it has a discharge of the order of 10 m<sup>3</sup>/sec at its starting point, while at the downstream end of its discharge is approximately 1.0 m<sup>3</sup>/s. The route of the main canal is located along the contour lines on the mountain, and the selection of route is made in such a way to attain a satisfactory balance between the excavations and the embankments. The lateral canals are arranged as either perpendicular or parallel to the main canal. The amount of the diversion discharge is of the order of 0.5 m<sup>3</sup>/sec through 1.0 m<sup>3</sup>/sec.

(2) Type of canal

In principle, both main canal and lateral canal will be earth lined type ones. The slope of the topography of this area is gentle (1/2000 through 1/4000) and the construction of the lining in the canal results only slight reduction of the cross section and is not economical.

The ground of the paddy area where these main and lateral canals are located is mostly composed of clayey soil or silty clay, and practically impermeable. The earth lines system will be adopted in both the main canal and the lateral canal, in view of the merit of using excavated earth materials to the embankment of the canal. (Refer to Figure 15.3.1 of the Supporting Report).

(3) Cross section of the canal

The standard design criteria of the NIA will be adopted as cross section of the canal. The standard design criteria of the NIA are presented in the next page. The distribution of slopes of the main canal and the cross section of the canal in accordance with the standard design criteria are presented in Table 15.3.1 and Table 15.3.2 of the Supporting Report.

- (a) Side slope 1:1.5
- (b) Allowable velocities 0.5 m/s through 1.0 m/s for big canal

Minimum velocity: 0.3 m/sec for small canal.

- (c) Hydraulic formula for open canal flow

$$\text{Manning's Formula } V = \frac{1}{n} \cdot R^{2/3} \cdot I^{1/2}$$

n = 0.025 for earth-lined canals

n = 0.030 for farm ditches

- (d) The base width (b) to depth (d) relationship

$$b = 2d \dots Q < 4.00 \text{ m}^3/\text{sec}$$

$$b = 2.5d \dots 4.0 \leq Q < 9.0 \text{ m}^3/\text{sec}$$

$$b = 3.0d \dots Q \geq 9.0 \text{ m}^3/\text{sec}$$

- (e) Elevation of the water surface during crop cultivation should be set at least 30 centimeters above the ground surface from the point where the canal can already be irrigated.

- (f) Free board

(i)  $Fd = 0.4d > 0.3 \text{ m}$  in case of  $d < 1.99 \text{ m}$

(ii)  $Fd = 0.25d + 0.30 < 2.0 \text{ m}$   $d > 2.0 \text{ m}$

- (g) Top berm width

For operation and maintenance

$$B = 6.0 \text{ m for main canal}$$

$$B = 4.0 \text{ m for laterals and sub-laterals}$$

### 15.3.3. Existing irrigation facilities

The maximum potential irrigable area covered by the existing irrigation facilities is approximately 3,000ha, according to data provided by the NIA. However, only 30-50 percentage of the area is irrigated. As a matter of fact, there are existing irrigation facilities in the area but the capacity is insufficient and the shortage of water occurs during the dry season. The irrigable area is located at elevations lower than new irrigation system of the project.

Therefore, the area irrigated by the existing facilities should be included in the service area of this project and is necessary to rehabilitated in some portion.

The regional water utilization associations has been organized around the existing irrigation facilities, and composed a local community from the historic and social points of view. Therefore, in case of setting up layout of irrigation systems, it should be considered in such a way to put such water utilization organizations into practical use, and the existing canals should be connected with newly constructed irrigation systems.

## 15.4. Related Canal Structures

### 15.4.1. Diversion works/check gates

In principle, the diversion works from the main canals will be used together with check gates. Each diversion work from the secondary canals will be planned in such a way to cover an paddy area of approximately 50ha.

#### 15.4.2. Siphon

Siphons will be used at places where the canal crosses rivers, while aqueducts will be used at places where the canal crosses deep valleys. Siphons will be constructed at approximately 10 places in the main canal and at approximately 3 places in the lateral canals. The largest ones are the siphon crossing the Alaminos River in the main canal and the siphon crossing the Maseden River in the lateral canal.

#### 15.4.3. Culverts

Culverts will be provided as drainage culverts, at places where the canals cross the drainage ditches. Box culverts made of concrete are recommendable, but pipe culverts can also be used, depending upon the size of the drainage ditches. Culverts will be installed at approximately 10 places in the main canal and at approximately 7 places in the lateral canals.

#### 15.4.4. Bridges

At places where the canals cross provincial roads, it is necessary to construct bridges.

Bridges will be constructed at 10 places in the main canal and 18 places in the lateral canals.

Besides those ones mentioned above, the construction of foot bridges (B = 2.0 m) is required at intervals of 2 km in the lateral canals.

#### 15.4.5. Spillway

Spillways will be provided at the upstream side of siphons and in principle at places where the capacity and cross section of the canal is changed by 5% through 10%. A total of 22 spillways will be required at the main canal.

The outline of the structures mentioned above are presented in the Design Criteria of the NIA and therefore they will be used in the project. The list of the main structures and their locations are presented in Figure 15.4.1 and Table 15.4.1 of the Supporting Report.

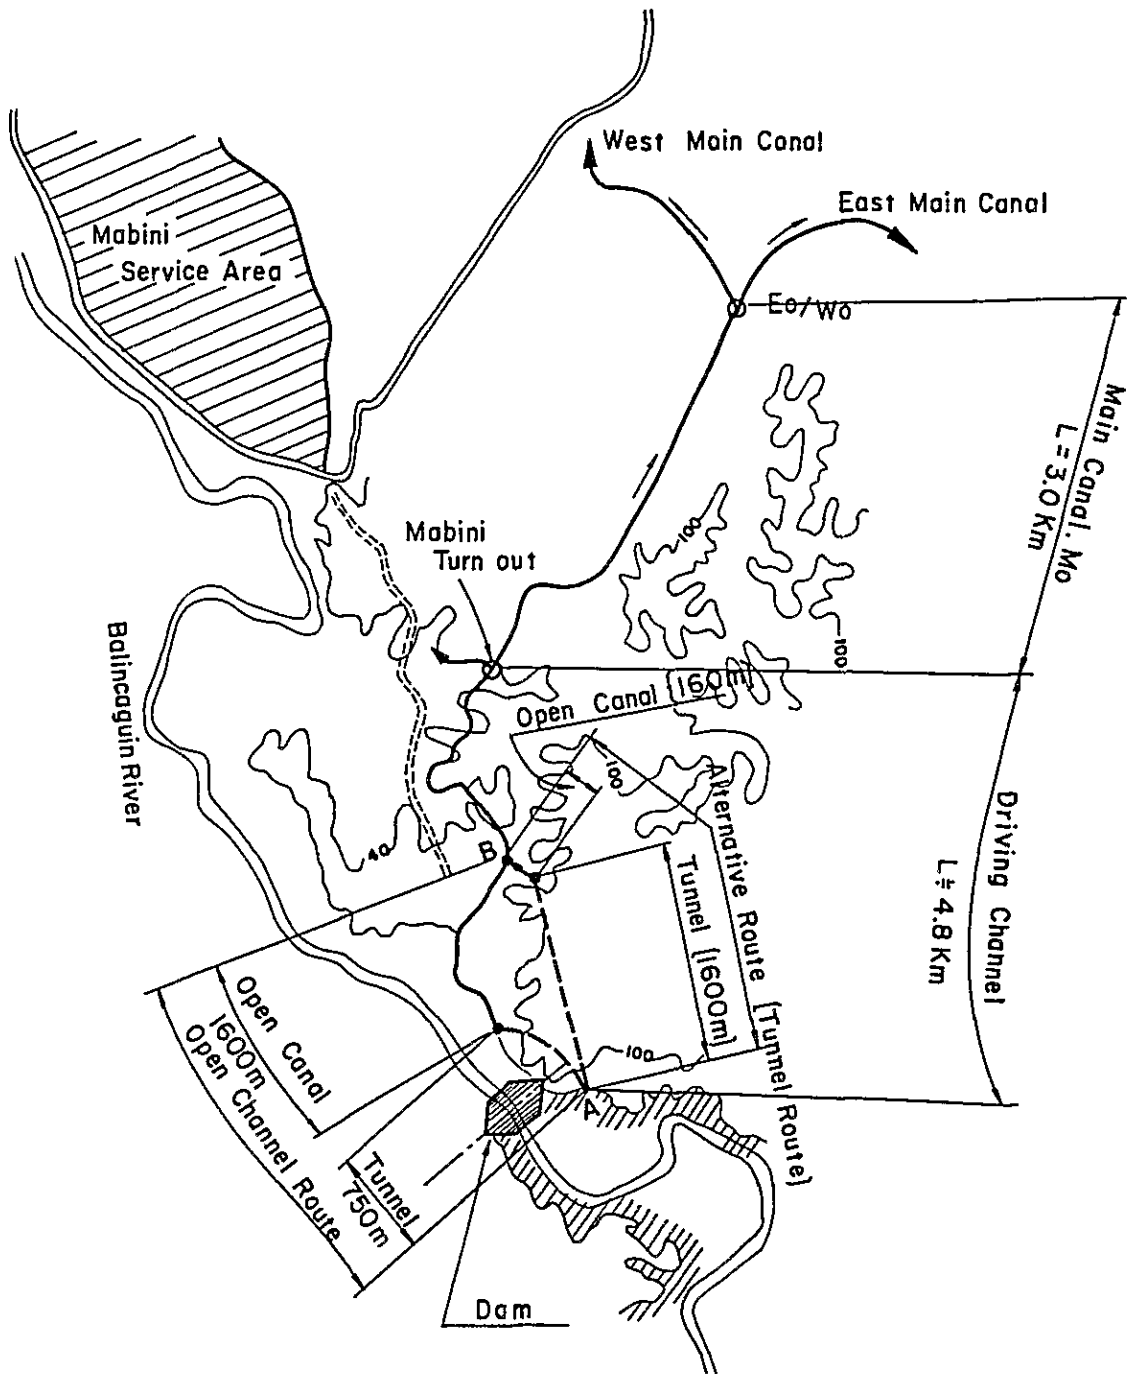

#### 15.5. Roads for Operation and Maintenance

There are two provincial roads located crosswise at the center of the 11,500ha service area. They have a very convenient configuration for the sake of planning the future road network. The network of roads required for maintenance and operation of the irrigation system will be connected to the said provincial roads.

The extensions of the main canal and lateral canals are 50 km and 135 km, respectively. These canals require the respective maintenance and operation roads. Data regarding the width of the said roads are contained in the Design Criteria of the NIA and they are perfectly able to be used in the present project. Excerpts of the Criteria are presented in the paragraph 15.5 of the Supporting Reports.

### 15.6. Drainage

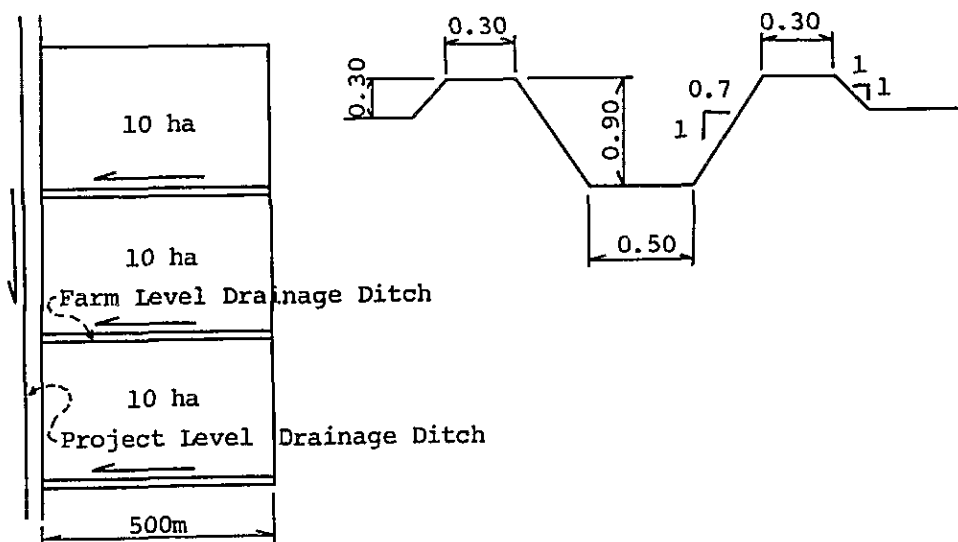

The drainage component of the Mabini Agricultural Development Project may be divided into two; namely project level drainage and farm level drainage. It may be preferable to implement project level drainage after the irrigation system of the project is completed, as farmers of the area are likely to be eager to obtain water for irrigation as soon as possible and are not keen to eliminate drainage problems without securing irrigation water. Farm level drainage is therefore included in this stage of the project.

In formulating the farm level drainage, unit water amount of drainage in the area was taken from the Design Criteria of the NIA as follows;

$$q = 6.0 \text{ Liter/sec/ha}$$

Density of drainage ditches in farm level will be about 50 m/ha. The construction cost of drainage system was estimated.

Layout and cross section of the drainage ditch are showing as follow.

## **CHAPTER 16**

### **CONSTRUCTION MANNER OF THE PROJECT**

10

10

## 16. Construction Manner of the Project

### (1) Outline of Construction Manner

The construction of the Mabini Dam is characterized by the excavation of the cut-off trench in the river deposit with a depth of approximately 30m. Prior to starting the excavation of the trench, it is required to complete the construction of the diversion tunnels and the construction of the cofferdam. The excavation of the both abutments and spillway, which has no influences from the river flow should be started before completion of the cofferdam. The grouting of both abutments should be carried out in parallel with the excavation of the riverbed trench. The embankment with a total volume of 3,854,800 cubic meters should be started after the riverbed grouting. Excavated materials, except topsoil and organic materials, should be used for the embankment materials, either directly or after stockpiling. The filter material should be obtained by screening and washing the river deposit. Concrete should be mixed at a mixing-plant installed at the dams site, by using river deposit as aggregate. The CRITICAL PATH of the construction of the project is presented in Figure 16.1.

### (2) Diversion Tunnel

Two diversion tunnels will be constructed at the right bank of the dams site. The half-face excavation method will be adopted in the construction of these two tunnels, because they have a larger diameter (8.5m). The excavation will be started from the upstream and downstream end of the tunnels, working in two shifts. Excavation will be carried out by using tractor shovels and dump trucks. The plan for the construction of these two tunnels should be drawn out in such a way to make possible the diversion of the sliding form of

the arch and the sliding form and center of the side walls. These sliding form of 10.5m and the concrete pump should be used for arch lining, while the sliding forms of 7.5m and two sets of centers of 3m should be used for the side wall lining.

(3) Excavation of the Riverbed Trench

The most critical problem at the excavating of the river deposit with thickness exceeding 30m is how to dewater the seepage water. It is recommendable to construct cutoff walls of slurry trenches at the upstream and downstream side in order to reduce the infiltration of water. The submersible pump should be adopted in order to drain infiltrated water springing out at the excavation site and continued until the back fill of embankment will be reach to the original river bed. The excavation at the two abutments of the dam-site should be carried out by bulldozers and ripper-dozers, and the river deposit should be removed away by motor-scrappers with bulldozers working as pushes.

(4) Grouting

Grouting should be started after finishing the excavation of the abutments and the riverbed, by using sets composed of two drilling machines, one grouting pump and one grouting mixer, 5 sets will be used for the grouting work. The consumption of the cement grouting is estimated at 3 bags of cement per meter.

## (5) Embankment

### Core

Borrow area is selected in the reservoir areas. Excavation and hauling by motor scrapers with pushers, spreading by bulldozers and compaction by sheepsfoot rollers will be used.

### Filter

Sand and gravel of the river deposit will be used as filter material, after washing and screening. The loading and hauling will be carried out with a combination of tractor-shovels and dump-trucks, while spreading and compaction will be carried out by bulldozers and vibrating rollers.

### Transition

For transition zone, excavated materials from other structures (mainly spillway) are expected to be transported either directly or via storage stockpiling. The combination of tractor-shovels and dump-trucks will be used for loading and hauling, while bulldozer and vibrating rollers will be used for spreading and compaction.

### Rockfill

It is expected that large quantities of quarry-run materials will be used as rockfill. The quarry site will be excavated by the bench-cut method and the type of explosive used in this case will be dynamite. The same types of construction machinery used for the construction of the transition will be used.

(6) Spillway

The construction of the spillway should be set forth practically in parallel with the embankment, because the large quantities of excavated material will be utilized for the dam embankment. The excavation of rocks of which seismic wave velocity not exceeding 2 Km/sec is planned by using ripper-dozers, because it is considered that such kinds of rock is slightly soft and rippable. However, the fresh rocks will be excavated by the bench-cut method using dynamite. The finishing surface of excavation will be protected by pre-splitting. Concrete will be transported from the mixing plant by concrete-mixer trucks and will be placed by concrete pumps.

(7) Irrigation facilities

The construction of irrigation canals will be set forth in parallel with the construction of the dam, and they will be concluded within 5 years. Backhoes, dump-trucks, bulldozers and sheepsfoot rollers will be the major machinery to be used for the construction of the earth lining canals. It is expected that the lateral canals will be constructed mainly by embankment. Accordingly, earth required for the construction of the lateral canals will be excavated and transported from the borrow areas selected in advance.

The schedule of the construction work described above is presented in Figure 16.2.

**CHAPTER 17**  
**CONSTRUCTION COST**

17. Construction Cost CONSTRUCTION COST (4)

(1) Construction Cost

The total construction cost of 1,017.0 million pesos (127.1 million US\$) consists of 571.5 million pesos (71.4 million US\$) of foreign currency and 445.6 million pesos (55.7 million US\$) of local currency. The breakdown of the construction cost is presented in Table 17.1

The construction cost is divided into 697.7 million pesos (87.2 million US\$) of the cost of dam construction cost and 319.3 million pesos (39.9 million US\$) of the cost of the irrigation facilities. The breakdown of these construction costs are presented in the Tables 17.2 and 17.3.

(2) Unit Prices

For the cost estimation, the unit prices in 1981 are adopted. The cost of machinery is calculated by converting the rental rates - October 11, 1979 "Revised Rental Rates for Use by All NIA Construction Equipment and Motor Vehicles" - into unit prices of 1981. The rental rates are applicable for only machinery possessed by the Philippine Government. Regarding the other types of machinery, the depreciation costs and the repair costs are estimated.

(3) Contingencies

Physical contingencies and price escalation due to the inflation should be included in the project cost. An amount equivalent to 10% of the construction cost will be physical contingencies. As for the price escalation, the price escalation ratios presented in Table 17.4 are adopted.

(4) Annual Construction Costs

The annual distribution of the construction cost, calculated based upon the project construction schedule, are presented in Table 17.5. The first year of implementation of the project is assumed to be 1983 and the price escalation is estimated.

(5) Classification of Local Currency and Foreign Currency

The following percentage of foreign currency of the various required materials determined by NIA "Basic Rate for Cost Estimate" are adopted.

|                          |      |
|--------------------------|------|
| 1) Cement                | 75%  |
| 2) Steel bars & hardware | 80%  |
| 3) Fuel & oil            | 50%  |
| 4) Equipment rental      | 75%  |
| 5) Sheet pile            | 100% |

## 18. Economical Evaluation

### 18.1. Benefits of Irrigation

The four towns which is located in the project area, have an administrative area of approximately 70,000ha, with approximately 26,000ha of agricultural land. The paddy harvested area in the rainy season of 1981 was 17,441ha, 15% of that corresponding to 2,559ha were of irrigated paddies. During the dry season of 1981 the paddy harvested area was only 40% of the irrigated area of the rainy season, i.e., 1,036ha.

Cultivation of paddy in two seasons by irrigation facilities will be possible throughout the whole service area (11,500ha) after completion of the project, being therefore expected a considerable increase in the production of paddy in the project area.

#### Utilization of land (ha)

|              | Present Situation | After completion of the project |
|--------------|-------------------|---------------------------------|
| Rainy season |                   |                                 |
| - Irrigated  | 1,700             | 11,500                          |
| - Rainfed    | 9,800             | 11,500                          |
| Dry season   |                   |                                 |
| - Irrigated  | 700               | 11,500                          |
| TOTAL        | 12,200            | 23,000                          |

The paddy yield per unit area in the project area during the rainy season and during the dry season are 3.16 ton/ha and 3.19 ton/ha, respectively. The yield per unit area

prevailing presently are low, because the supply of a sufficient irrigation water is not possible through the existing irrigation facilities.

However, the stable supply of a sufficient irrigation water will be possible after completion of the project. The yields in the rainy season and the dry season are expected to be increased by approximately 1.45 times and 1.5 times, respectively, as a result of the strengthening of favourable factors like the introduction of high yielding varieties, effective application of fertilizer and agricultural chemicals, etc., in addition to the supply of irrigation water.

Yield (ton/ha)

|              | Present<br>Situation | After completion<br>of the project |
|--------------|----------------------|------------------------------------|
| Rainy season |                      |                                    |
| - Irrigated  | 3.16                 | 4.48                               |
| - Rainfed    | 1.93                 | (1.93)                             |
| Dry season   |                      |                                    |
| - Irrigated  | 3.19                 | 4.79                               |

The annual production of paddy is expected to become 81,236 tons, as a result of the expansion of the cultivated area and as well as of the yield per unit area.

Production of paddy (ton)

|              | Present<br>Situation | After completion<br>of the project |
|--------------|----------------------|------------------------------------|
| Rainy season |                      |                                    |
| - Irrigated  | 5,372                | 52,670                             |
| - Rainfed    | 18,914               | -                                  |
| Dry season   |                      |                                    |
| - Irrigated  | 2,233                | 55,085                             |
| TOTAL        | 26,519               | 107,755                            |

The benefit attributable to the increase of production, calculated based upon the export price of rice, will be 112,497,000 Pesos per year.

18.2. EIRR

(1) Costs

The cost of project consists of the construction costs and the maintenance and operation costs. The taxes and interests are excluded, and the labour costs are calculated from the economic cost taking into consideration the shadow wage rates.

The conversion factor (0.827) prevailing in the Philippines is applied to the construction costs in general, while the standard conversion factor (0.820) is applied to the maintenance and operation cost, for the conversion of the financial costs into economic costs.

Cost of the Project  
(1,000 Pesos, Economic Cost, 1981 Constant Price)

|          |         |
|----------|---------|
| 1st year | 104,948 |
| 2nd year | 92,945  |
| 3rd year | 134,881 |
| 4th year | 135,197 |
| 5th year | 119,402 |
| 6th year | 33,550  |
| TOTAL    | 620,923 |

The maintenance and operation cost required annually is 3,772,000 Pesos.

(2) Benefits

The amount of annual benefit caused by the irrigation facilities and others is 115,331,000 Pesos. This benefit will be raised after the 7th year from starting of the project construction, when the dam will be full to its high water level. The construction of the dam and other related facilities will be completed in the 6th year.

(3) Life of the Project Facilities

It is assumed that the project will have a life duration of 50 years after starting full scale operation.

(4) IRR

The IRR (Internal Rate of Return) of the project calculated at 12.8%.

### 18.3. Indirect Benefits

#### 18.3.1. Increase of Income of Farmers

The average farm land holding of farmers living in the project area is about 1.5ha. The future farm budget of the farmers living in this area, calculated based upon the farming area mentioned above is presented in Table 18.4.1.

If this project is not implemented, the annual income of an average farmer living in this area is expected to be 9,191 Pesos even in case of cropping two seasons of paddy. However, after the completion of the project the income is expected to increase to 16,667 Pesos, approximately 1.8 times of the income without project. However, the figures refer to land owner farmers, and in case of tenant farmers, it is required to discount the sharecropping charge from the said income. Presently, most of the tenant farmers pay tenant in fixed amount basis, and the tenant charge is of the order of 6 cav/ha/crop (1 cav = 50Kg). In case of share-croppers, 25% of the harvested quantity is shared by the landowner. The incomes corresponding to the farming modes are presented in the table below. From the considerations above, it is evident that the setting of an appropriate tenant system and fee is indispensable in order to give more impact for the paddy production to the tenant farmers.

Farm incom (Peso)

|                                    | Without Project       |                         |                 | With Project            |
|------------------------------------|-----------------------|-------------------------|-----------------|-------------------------|
|                                    | Rainfed<br>Paddyfield | Irrigated<br>Paddyfield |                 | Irrigated<br>Paddyfield |
|                                    |                       | One<br>Cropping         | Two<br>Cropping | Two Cropping            |
| Land owner<br>farmers              | 3,183                 | 4,503                   | 8,191           | 16,667                  |
| Tenant farmers<br>(fixed amount)   | 2,303                 | 3,623                   | 7,432           | 14,908                  |
| Tenant farmers<br>(share croppers) | 1,768                 | 2,186                   | 4,536           | 9,798                   |

18.3.2. Increase of Employment Opportunity

A labour force of 2,300,000 man-day will be required for agriculture sector after completion of the project, with an increase of 1,411,000 man-day compared with the situation of the without project.

The rate of unemployment in the four municipalities was 13.5% in 1975, which means 3,686 jobless workers. It will be possible to absorb such idle manpower in the agricultural sector and the dry season cropping will be possible in full scale after the completion of the project, contributing therefore to create employment opportunity all the year round.

18.3.3. Utilization of surplus water

The dam has a surplus of storage capacity in normal years, being therefore possible to supply the irrigation water to the additional areas by using the surplus water. (Refer to 9.4)

Table 18.1.1.1 NET VALUE OF PRODUCTION

|                   |      | Area   | Yield    | Farmgate | Gross Value | Cost       | Cost of    | Net Value  | Net Ret.   |

#### 18.3.4. Flood Control Benefits

##### (1) General

In addition, damages of flood used to occur in the area along the Balincaguin River from time to time. After the construction of the dam, it will be possible to control the flood flow of the river, and eliminate the flood damages.

##### (2) Study of the Previous Flood Tracing

###### 1) Inflow Hydrograph

Measurement records of inflow hydrograph are not available. The available data and information presently are as follows.

- Annual maximum flood discharge rate.
- Data regarding the time sequence of the aforesaid maximum flood.
- Cronological table of the daily rate of discharge.
- Data of the adimensional graph method for preparation of unit hydrograph in accordance with the NIA, etc.

The inflow hydrograph required for the study is set up by the available data with comprehensive consideration.

2) Method of Operation of the 4 Gates of the Spillway

The gates should be operated in such a way to keep the high water level of 63.0m at the beginning and decline stage of the flood, while when the water level exceeds the high level of 63.0m they should be fully opened.

Accordingly, the study of flood tracing is carried out by using the 4 gates planned in the dam as variables.

3) Analysis and Results of the Flood Tracing

As shown in Table 18.3.2, the 5 cases of flood with the highest levels of water are selected for the study. The number of spillway gates to be opened in order to discharge water and the summary of the results of flood tracing studies corresponding to them are presented in Table 18.3.2.

The graphical results of the flood tracking study regarding the floods occurred in August of 1968 and September of 1966 are presented in Figure 18.3.1 and Figure 18.3.2.

Table 18.3.2 Maximum Discharge Records and Results of Flood Control by the Dam

| Year | Date                | Maximum Inflow<br>(m <sup>3</sup> /s) | Maximum Outflow (m <sup>3</sup> /s) |                    |                    |                  |

**ORGANIZATION AND OPERATION**

Handwritten text at the top of the page, possibly a header or title, which is mostly illegible due to fading and bleed-through.

Handwritten text in the middle of the page, possibly a date or a specific reference.

Main body of handwritten text, consisting of several lines of cursive script, mostly illegible.

Handwritten text at the bottom of the page, possibly a signature or footer, which is mostly illegible.

## 19. Organization and Operation

### 19.1 Implementation of the Civil Work

#### Construction of civil works

The construction of civil works of the project will be carried out under the responsibility of the NIA and the power generating facilities under the responsibility of the NPC. At the occasion of the detail design, the preparation of specifications and the purchase of construction machinery, equipment and materials, the NIA and the NPC will employ the foreign consultants for the technical cooperation. The supervision of the construction work will be carried out by the foreign consultant. The organization for the implementation of the construction work is shown in Figure 19.1

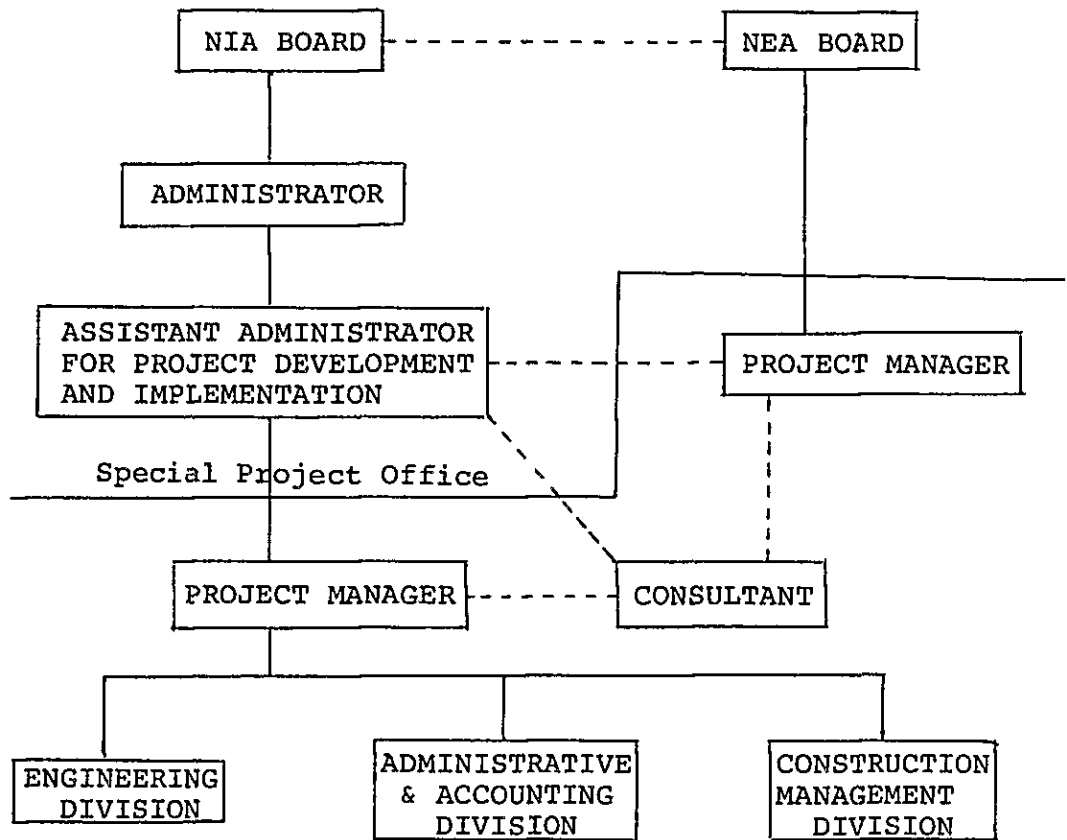

#### Compensation and indemnification

Resettlement of the people living in reservoir area and the vicinity of the dam-site to the service area should be performed with particular consideration.

### 19.2. Operation and Maintenance

The organization proposed for the operation and maintenance of the various facilities after completion is presented in Figure 19.2. The annual operation and maintenance cost estimated at 4 million Pesos and the breakdown of the cost is presented in Table 19.1.

## A. Power Generation

### A-1 Present Situation and Future Plan of the Philippines' Electrification

Due to the oil-crisis which shook the world economy in 1970's, the socioeconomic development program of the Philippines had to be dramatically revised.

The government of the Phillipines has been carrying out the Five Year Development Plan for the period from 1978 to 1982, and one of its most important issues is the development of the national energy. Nevertheless, it is foreseen that the energy development should be accelerated after 1983, with faster pace and in much larger scale.

The total installed capacity of power plants in the Philippines in 1980 is 3,766 MW and the total annual generated energy is 15,086 (GWh). Even if all power plants now under construction are completed, the overall installed capacity of the power plants in the Philippines' would be only 5,737.5 MW, while the whole demand of power in 1991 would reach some 10,000 MW when we assume the fugure rate of increase as 7%, taking into consideration of both the future rate of popula-tion increase (3%) and the tendency of the improvement of liv-ing standard of the people. The government has to make its utmost efforts to solve the future energy problems from all aspects, by installing new power plants of more than 4,000 MW in addition.

The electricity in the Philippines has been supplied by the National Power Corporation (NPC), the Meralco System, the National Electrification Administration (NEA), and the Local Electric Cooperative Inc. which has been holding power plants built by private enterprises. The next tables, (Table A-1 and A-2 of Supporting Report) show the summarized instal-

led capacity of the existing power plants (in 1980) divided in three systems in the Philippines and also the installed capacities of plants under construction. As seen in the Table A-2, the Philippines' power plants are of various types which include hydro, thermal, nuclear, geothermal and others. For the non-oil producing country like the Philippines, however, the development of the hydro-potential which still amply remains in various parts of this country should be, first of all, taken up and be implemented as fast as possible; it would be needless to emphasize that the development which utilizes the nation's own natural resources, i.e. water, would not cause air-pollution problems, while helping people living in the remote areas of the country. Once it is developed, it would not only supply cheap energy but also be operated quite easily.

The local electrification in the Philippines has been carried out along the line with the plan and policy of the National Electrification Administration (NEA). According to the plan, it is expected that 20, 50, and 100% of the electric energy required by the Local Electric Cooperative Inc. could be supplied by 1982, 1987, and 2000, respectively. On the other hand, the development of the small scale hydro-power plants has been initiated in 1930's, and, at present, many power plants are being operated such as the ones in Benguet Province in Luzon and others. Today, the total installed capacity of such small hydro power plants in Luzon, Mindanao, and Visaya exceeds 6,700 kW, 3,000 kW, and 1,000 kW, respectively (See Table A-3 of supporting report). The development of such mini-hydro plants should certainly be expedited faster and in the larger scale all over the country in the future in view of the increasing cost of the imported oil.

The Philippines is blessed with its high humidity and temperature, and its average annual precipitation exceeds 2,000 mm (3,000 mm even in some areas). It is also blessed

with its topography, and we can find many places suitable for creating dams and reservoirs in various parts of the Philippines. It is therefore to be always taken into account to check a possibility to develop hydro-potential as much as possible whenever the construction of a dam and reservoir is considered even if the dam project was mainly planned to increase agricultural production.

It was therefore concluded that the physical, socio-economic feasibility should be studied for the direction to provide hydro-power plants in the Mabini Agricultural Development Project.

## A-2 Power Generation

### (1) Power Generation

The power generation is planned based upon the following conditions: the hydroelectric power plants are to be provided as an accessory facility of the irrigation project, and the design of civil engineering works of the irrigation project is not modified by the construction of the power plants. Therefore, it is not required to allocate the construction costs of dam and related facilities to the power component.

#### a) Power generation with irrigation water

It is possible to generate electricity by irrigation water during the irrigation season during the dry season, at the downstream end of the tunnel, by utilizing the water head between the water level of reservoir and the stilling basin elevation.

#### b) Generation of power with surplus water during rainy season

It is possible to generate electricity with water discharged from the dam to the river just at the downstream of the damsite during the rainy season, by utilizing head between the water level or reservoir and of the downstream riverbed.

### (2) Installed Capacity

The following considerations are applied to the power generation with regard to the irrigation as well as the river maintenance.

|   |                          |
|---|--------------------------|
| - Maximum consumption of irrigation water (approximately)                         | 21.7 m <sup>3</sup> /sec |
| - Average discharge required for river maintenance purpose at the downstream side | 2.3 m <sup>3</sup> /sec  |
| Total   | 24.0 m <sup>3</sup> /sec |

|  |            |
|--|------------|
| a) Normal water surface  | EL 63.00 m |
| Low water surface  | EL 38.00 m |
| Turbine center water surface                                       | EL 37.00 m |
| Rated water surface  | EL 55.00 m |
| Rated water head (Hr)  | 18.00 m    |
| Length of pressure tunnel (L)                                      | 1,000.00 m |
| Water head loss (Hl) = $l/1,200 \times L + Hr \times 0.02 = 1.2$ m |            |
| Effective water head He = 18.00 m - 1.20 m = 16.8 m                |            |

$$P = Et \times Eq \times 9.8 \times Q \times He \doteq 3,000 \text{ kW}$$

P : Power generating capacity

Et: Turbine efficiency 80%

Eq: Generator efficiency (3-phase synchronous) 95%

Q : Discharge 24.0 m<sup>3</sup>/sec ... Dry Season

(Hereinafter this power station is called POWER STATION A)

|                                |            |
|--------------------------------|------------|
| b) Normal water surface        | EL 63.00 m |
| Low water surface              | EL 38.00 m |
| Water level of turbine surface | EL 15.00 m |
| Riverbed elevation             | EL 12.50 m |
| Rated water surface            | EL 55.00 m |
| Rated water head (Hr)          | 40.00 m    |
| Length of pressure tunnel (L)  | 1,200.00 m |

Water head loss  $H_l = 1/1,200 \times L + H_r \times 0.02 = 1.8 \text{ m}$

Effective water head  $H_e = 40.00 \text{ m} - 1.80 \text{ m} = 38.2 \text{ m}$

Q: Discharge  $24.0 \text{ m}^3/\text{sec}$  ... Wet Season

$P = E_t \times E_g \times 9.8 \times Q \times H_e \doteq 7,000 \text{ kW}$

(Hereinafter this power station is called POWER STATION B)

The Power Station A is operated during the dry season by using irrigation water, while the Power Station B is operated during the rain season by using water for river maintenance and the surplus water.

### (3) Generated Energy

As described in the Supporting Report, the total quantity of energy to be generated by the Power Stations A and B is approximately  $25 \times 10^6 \text{ kWh}$ . This generated energy can be consumed with ease in the 69 kV transmission line system of the NPC located in the project area, because the 69 kV transmission system has an extremely large capacity compared with the power generating capacities of the power stations A and B.

A-3 Revenue and Expenses

(1) Construction Cost

Table A-1 Construction cost

Unit: ₱1,000.

| Item  | Nos.  | Price   | Total Price |
|---|-------|---------|-------------|
| <u>A Power Station 3,000 kW</u>                         |       |         |             |
| Including accessories, outdoor switching station        | 1 lot | 20,000. |             |
| Installation works, foundation and power house          | 1 lot | 5,000.  | 25,000.     |
| <u>B Power Station 7,000 kW</u>                         |       |         |             |
| Including accessories, outdoor switching station        | 1 lot | 40,000. |             |
| Installation works, foundation, power house & residence | 1 lot | 15,000. | 55,000.     |
| <u>Gates for A &amp; B Power Station and Bypass</u>     |       |         |             |
| Gates and accessories                                   | 1 lot | 3,000.  |             |
| Installation works and civil works                      | 1 lot | 1,500.  | 4,500.      |
| <u>Penstock 100 ton</u>                                 |       |         |             |
| Laying work & civil works                               | 1 lot | 3,500.  | 6,000.      |
| <u>Surge tank 100 ton and accessories</u>               |       |         |             |
| Installation works & civil works                        | 1 lot | 2,500.  | 5,000.      |
| <u>69 kV transmission line 12 km</u>                    |       |         |             |
| Conductor & accessories                                 | 1 lot | 1,400.  |             |
| Wooden pole & installation works                        | 1 lot | 1,600.  | 3,000.      |
| <u>69 kV Switching Station</u>                          |       |         |             |
| Including accessories                                   | 1 lot | 1,000.  |             |
| Installation works and connection work to NPC line      | 1 lot | 500.    | 1,500.      |

Table A-1 Construction cost (Cont'd)

Unit: ₱1,000.

| Item   | Nos.  | Price   | Total Price |
|--|-------|---------|-------------|
| 69 kV distribution line & communication devices  |       |         |             |
| (Intake - Dam - A PS. - B PS.)   |       |         |             |
| Including accessories, line, remote control system devices and water level devices and communication devices | 1 lot | 6,000.  |             |
| Installation works   | 1 lot | 1,000.  | 7,000.      |
| Contingency  |       | 13,000. | 13,000.     |
| Total  |       |         | 120,000.    |

The main civil works for the construction of the irrigation facilities are not influenced by the construction of the power station A and B.

(2) Power Rate

1) The Annual income

According to the study at the Panganisan I Electric Corp. Inc. Bani Pangasinan, the unit price of electric power in the project area is as follows.

Table A-2 Unit cost of electricity

| Type of Consumer              | Content                 | Rate₱            |
|-------------------------------|-------------------------|------------------|
| Residential & Public Building | Minimum Bill 1 - 12 kWh | 9.45             |
|                               | Excess / kWh            | 0.79             |
| Commercial                    | Minimum Bill 1 - 12 kWh | 10.20            |
|                               | Excess / kWh            | 0.85             |
| Industrial                    | Demand Charge / kW      | 15.00            |
|                               | Energy Charge / kWh     | 0.78             |
| Irrigation                    | Demand Charge / kW      | 15.00            |
|                               | Energy Charge / kWh     | 0.71             |
| Street Lights                 | 175 W bulb / month      | (0.626)<br>39.50 |
|                               | Rate / watt             | 0.226            |
|                               | Mean rate / kWh         | 0.751            |

According to the report of the NPC, the unit price per kWh in the Luzon System is 0.48 Pesos.

The annual income is calculated as follows, by assuming this unit price.

$$0.48 \times 25,120,000 \text{ kWh} = 12,057,600 \text{ (Pesos)}$$

- 2) Calculation for Investment cost/kW and Generating power cost/kWh:

Assuming the total Investment costs for A and B Power Station including Transmission line and Switching station are ₱120,000,000, the Investment cost/kW is as follows.

$$\text{₦120,000} \div (3,000 + 7,000(\text{kW})) = \text{₦12,000} = \$1,568/\text{kW}$$

Assuming the factors undermentioned as follows,

|   |      |
|---|------|
| (a) Rate of interest per year                         | 4.5% |
| (b) Rate of depreciation per year<br>(Life: 50 years) | 2.0% |
| (c) Rate of fixed property tax per year               | 1.4% |
| (d) Rate of operation & miantenance per year          | 0.5% |
| (e) Rate of incidental expenses per year              | 0.5% |
| Total   | 8.9% |

Assuming the total kWh per year is 25,120,000 kWh,  
the generating power cost per kWh is as follows:

$$\text{kWh cost} = \frac{\text{₦120,000,000}}{25,120,000} \times 8.9\% = \text{₦0.425}$$

According to the World Bank Report for the develop-  
ing countries in 1980, the Investment cost/kW, Fuel  
cost/kWh and Generating power cost/kWh are as fol-  
lows:

Table A-3

| Kind       |                                 | Investment<br>cost/kW<br>* unit Dollar | Fuel<br>cost/kWh<br>unit Cent | Generating<br>power<br>cost/kWh<br>unit Cent |
|------------|---------------------------------|--|-------------------------------|--|
| Hydro      | Large scale, High head          | 1,100                                  | non                           | 2.4  |
|            | Small scale, Low head           | 3,500                                  | non                           | 12.7   |
| Diesel     | Large scale, Heavy oil          | 1,000                                  | 4.2                           | 6.7  |
|            | Small scale, Light oil          | 800                                    | 10.9                          | 13.2   |
| Thermal    | Large scale, Natural gas        | 800                                    | 0.4                           | 2.4  |
|            | Large scale, Coal               | 1,000                                  | 2.7                           | 5.2  |

| Geothermal | Dry steam                       | 1,400                                  | non                           | 3.0  |
|            | Wet steam or Hot water          | 2,800                                  | non                           | 6.0  |
| Nuclear    | Large scale, Composite<br>units | 1,600                                  | 1.0                           | 5.1  |
|            | Small scale, Single unit        | 2,200                                  | 1.0                           | 7.4  |
| Solarheat  |                                 | 20,000 - 30,000                        | non                           | 100 - 300                                    |
| Wind force |                                 | 5,000 - 15,000                         | non                           | 30 - 100                                     |

\* Including the cost of Transmission and Distribution line in the Investment cost/kW. Excepting the cost of Battery in the Investment cost/kW of Solar heat and Wind force.

3) Benefits expected from the generation of electricity

Power will be generated in the present project by utilizing the head of water used for irrigation purpose. The annual generation of energy will be 25,000,000 kWh. This electricity will be supplied for the general use through the NEA.

The benefit expected from the generation of electricity is expressed in terms of cost required for the development of alternative power sources. In the present case, a small scale thermal generation would be considered as an alternative source of power. In case of a small scale thermal generation, power rate at generation end is 11.4 Cent/kWh or 0.91Pesos/kWh ( refer to Table A-3 ). Accordingly, the benefit expected from the generation of electricity will be as follows;

$$25,120,000\text{kWh} \times 0,91\text{Pesos/kWh} = 22,859,200\text{Pesos}$$

#### A-4 Conclusion

The Mini hydro power development supplemented to the Project will be able to generate power which will be useful for the promotion of the social economic, and industrial growth and the commercial activities, and will achieve the electrification all over this region.

The hydro-electric power may be resulted in the reduction of dependence on the imported fossil fuel in its own way.

At any rate, the mini hydro power development shall be considered to be provided in the Mabini Agricultural Development.

Including power generation benefit, EIRR is 13.3%
