## 1. INTRODUCTION

This Annex was prepared to present the data used, methods applied and consequent results of the domestic and industrial water demand (D&I water demand) study for the Region in the years of 1983, 1985, 1990, 1995, 2000 and 2005. Both water demands to be supplied by public system, i.e., Public Works Department (PWD) and Rural Environmental Sanitation Program (RESP), and by private supply system, were estimated.

The D&I water demand was classified into (1) domestic water demand including commercial and public water use (D water demand), (2) water demand of manufacturing industries (M water demand) and (3) agro-based industries water demand such as palm oil mills, rubber factories, and pineapple canning factories. All the demand were estimated in terms of source demand (S.D.), either at intake points in rivers or wells on the basis of customer demand (C.D.). In order to serve for the water balance study, and water pollution study, S.D. and C.D. were estimated by water intake, by type of supply system, by purpose of supply and by town and rural area.

## 2. PRESENT CONDITION OF D&I WATER SUPPLY AND USE IN THE REGION

### 2.1 Organization

Public water supply in the Region is administered by the following public organizations:

- (1) Public Works Department (PWD) and
- (2) State Government, under Rural Environmental Sanitation Program (RESP)

In principle, PWD of the State is responsible for domestic and industrial water supply in the State of Johor. However, untreated water is supplied with the technical and financial assistance of Ministry of Health (MOH) to the isolated rural area that will not be reached by PWD water supply system near future under RESP.

Recently, PWD and MOH discussed on the coordination of activities and both parties reached an agreement concerning the allotment of supply areas for PWD and RESP with the target of full supply of potable water to the State population including the Region.

### 2.2 PWD Water Supply and Use

In the State of Johor, PWD has 46 intakes for water supply and each intake has its own treatment plant adjacent to it. Out of these, 15 facilities are located within the Region. Direct pumping from the river is normal practice, but dams are provided for the Simpang Renggam, Layang and Lebam schemes.

Furthermore, there are three dams with intakes in Gunong Pulai area represented by Gunong Pulai dam and three river intakes in the Johor, Skudai and Tebrau rivers owned by the Public Utility Board (PUB) of Singapore. The locations of intake are shown in Fig. 1. Some details of intakes are shown in Tables 1 and 2.

PWD supplied treated water of  $72.6 \times 10^6 \text{ m}^3$  in 1983 including  $44 \times 10^6 \text{ m}^3$  tapped from the water pipe lines of PUB system.

Unaccounted-for water is defined as the balance between the total treatment plant output and the total quantity of water metered. It comprises the followings:

- (1) Leakage from service reservoirs, mains, service connections,
- (2) Operation of hydrants and flushing mains,
- (3) Losses due to metering inefficiency, and
- (4) Unauthorized water abstraction.

Unaccounted-for water ratio (UA ratio) is defined as unaccounted-for water against treatment plant output. UA ratio varies from 20% in Kluang district to 40% in Kota Tinggi district having the average value of 30% according to the statistics of PWD in 1983 (Ref. 4).

With regard to domestic water use, present per capita consumption is 242 l/d in urban area and 140 l/d in rural area according to the statistics of PWD (Ref. 5). The domestic water consumption in Johor Bahru district is by far the largest in the Region. It amounted to  $32 \times 10^6 \text{ m}^3$  or 69% of the total domestic consumption.

The manufacturing water use in Johor Bahru district shared almost 80% of the total manufacturing water use in the Region in 1983, attributable to the highly populated towns such as Johor Bahru, Senai, Kulai and others and Pasir Gudang industrial estate.

Treatment plant use (TP) is defined in this Study as the amount of treatment plant water use for its own operation and loss between intake point and treatment point. TP ratio (treatment plant water use ratio) is defined as the ratio of treatment plant use against the quantity of water abstracted at intake point. In this study, the TP ratio was assumed at 5% for all facilities in the Region.

Each water supply facility is connected by the pipeline forming water supply network except eastern part of the Region. This network enables to supply water to a service area from multiple supply systems. Existing water supply system is shown in Fig. 2.

### 2.3 Rural Environmental Sanitation Program

Rural areas located distant considerably from PWD's water supply system have been supplied untreated water through RESP with the technical and financial assistance of MOH. Water supply facilities are constructed by local people who are to be benefitted. Operation and maintenance are also carried out by themselves. Almost all of facilities in the Region are simple wells except one direct intake from the river and one rain water collection system. In 1983, RESP systems in the Region supplied water to the population of about 10,000. The locations of RESP facilities are shown in Fig. 3. RESP supplied  $0.5 \times 10^6 \text{ m}^3$  of water in 1983.

### 2.4 Processing Water Use in Palm Oil Mills and Rubber Factories and Pineapple Factories

Palm oil processing is one of the thriving industry in the Region. A large scale palm oil refinery is constructed in the Pasir Gudang Industrial Estate. It is estimated that palm oil processing industry consumed about  $4,800 \times 10^3 \text{ m}^3/\text{y}$  of water in 1983 in the Region (Annex C).

In 1983, 20 rubber factories were on operation in the Region, which is estimated to have consumed water of  $1,700 \times 10^3 \text{ m}^3/\text{y}$  (Annex C). However, rubber production have been decreasing recently because rubber is substituted by oil palm.

In 1983, 5 pineapple factories are operated. Canneries were three factories and remaining two are only cutting. Pineapple factories are estimated to have consumed  $500 \times 10^3 \text{ m}^3/\text{y}$  of water in 1983 (Annex C).

## 2.5 Water Tariff, Revenues and Expenditures

In the State of Johor, a unique water tariff is charged to a water use both in urban or rural. However, different water tariff are charged to different water use. That for industrial use is rather higher than that for domestic and public water use.

In Sept. 1983, kinds of water tariff was increased from 2 categories to 4 categories as shown in Table 3.

Revenues and expenditures of the water supply division of PWD of the State of Johor are shown in Tables 4 and 5.

## 2.6 Water Supply to Singapore

The Public Utility Board (PUB) of Singapore has been abstracting raw water from rivers in the State of Johor for the purpose of domestic and industrial water supply. With this regard, State of Johor and Singapore have agreements, Indenture and Deed.

PUB has a dam in the Pontian Kechil river and two dams in the Pulai river with intakes. Those intakes are connected by pipelines and called Gunong Pulai dam system. In addition, it has intakes in the Skudai and the Tebrau rivers. Furthermore, it has an intake in the Johor river near Kota Tinggi. An abstraction record of raw water by PUB is shown in Table 6. In 1983, PUB abstracted raw water of  $145 \times 10^6 \text{ m}^3$  (241 Mgd) from the former three intake systems and  $99 \times 10^6 \text{ m}^3$  (60 Mgd) from the Johor river. Treated water of  $44 \times 10^6 \text{ m}^3$  (121 Mld, 26.5 Mgd) was diverted from the PUB system to PWD system in 1983.

The abstraction from the former three intakes are presumed to have reached to the upper most potentials of each river. The discharge capacity of the Kota Tinggi system was expanded from  $1.6 \text{ m}^3/\text{s}$  (30 Mgd) to  $3.2 \text{ m}^3/\text{s}$  (60 Mgd) in 1980 and further expansion to  $4.7 \text{ m}^3/\text{s}$  (90 Mgd) is under construction. The capacity is to be increased to  $6.3 \text{ m}^3/\text{s}$  (120 Mgd) in the near future. The expansion is committed to reach upto  $8.4 \text{ m}^3/\text{s}$  (160 Mgd).

### 3. EXISTING PUBLIC WATER SUPPLY PROJECTS

#### 3.1 Existing Development Plan in the Region for Water Supply

There are various water supply development plans in the Region. The schemes which are presently being implemented or committed for their implementation are identified in the following existing development plans:

- (1) Johor Bahru New Water Supply Scheme, Long Term Raw Water Sources, 1983, State PWD (Ref. 18);
- (2) Feasitiliby Study of Water Supply for West Johor Phase I & Phase II, 1983, Government of Malaysia (Ref. 19);
- (3) Feasibility Study for the Bekalau Air Baru Keluang (Ref. 20), Johor, 1984, Government of Malaysia;
- (4) Johor Timur Physical Regional Planning (Ref. 21);  
and
- (5) Water Supply to Johor Tenggara Development, 1974, Government of Malaysia (Ref. 22).

#### 3.2 On-going Source Development Plan

In this study, the schemes, implementation thereof have been committed are called the on-going schemes. The outlines of on-going schemes are given below:

- (1) Layang Scheme (Ib)

The second phase of the Johor Bahru New Water Supply Scheme undertaken by PWD is called the Layang Scheme Ib. In the first phase (Ia), Layang dam will be constructed in the upstream reach of the Layang river, a tributary of the Johor river by 1985, with a supply capacity of  $38 \times 10^6 \text{ m}^3/\text{y}$  (23 Mgd, 104 Mld). A treatment plant with a capacity of  $66 \times 10^6 \text{ m}^3/\text{y}$  (40 Mgd, 181 Mld) is also provided. An experimental estuary storage is to be formed by construction of the estuary barrage in the river mouth of the Layang river.

Under the Layang scheme (Ib), a pump station in the upstream reach of Chabang Tiram river, a tributary of the Johor river, and water way between the pump station and the Layang dam will be constructed by 1986, in order to increase the supply capacity of Layang dam by  $28 \times 10^6 \text{ m}^3/\text{y}$  (17 Mgd). Consequently the water supply capacity of the Layang scheme will be  $66 \times 10^6 \text{ m}^3/\text{y}$  (40 Mgd). Main supply areas of Layang scheme are Johor Bahru and Pasir Gudang.

(2) Simpang Renggam Scheme Stage I

In the Simpang Renggam Scheme Stage I, a treatment plant with a capacity of  $9.1 \times 10^6 \text{ m}^3/\text{y}$  (25 Mld) will be constructed at Simpang Renggam in the upstream reach of the Benut river by 1990, in order to abstract the released water from Macap dam. The water is to be supplied to the Pontian district and a part of Kluang district.

(3) Kluang Scheme Stage I

The main purpose of the Kluang Scheme Stage I is to supply water to Kluang district. Renggam, Sayong and Layang Layang in the Region belong to the southernmost part of the district and are included in the target area of water supply by the scheme. A treatment plant with a capacity of  $29.2 \times 10^6 \text{ m}^3/\text{y}$  (80 Mld) will be provided at the Semberong dam to abstract and supply the impounded water. At the same time, a groundwater project with an estimated yield of  $3.7 \times 10^6 \text{ m}^3/\text{y}$  (10 Mld) will be developed at the Kahang river flood plain. The scheme will supply  $0.1 \times 10^6 \text{ m}^3/\text{y}$  (0.3 Mld) to Sayong,  $1.5 \times 10^6 \text{ m}^3/\text{y}$  (4.1 Mld) to Renggam and  $1.1 \times 10^6 \text{ m}^3/\text{y}$  (3 Mld) to Layang Layang by 1987.

(4) Tapping of PUB water

The State of Johor have tapped treated water of  $44 \times 10^6 \text{ m}^3/\text{y}$  (121 Mld) on an average from the PUB's water supply facilities. It is confirmed that this rate of tapping will be maintained upto year 2005.

(5) Expansion of the capacity of Leban facility

Present supply capacity of Leban facility,  $10.8 \text{ m}^3/\text{s}$  (6.5 Mgd), will be expanded to be  $16.6 \text{ m}^3/\text{s}$  (10.0 Mgd) by 1990.

#### 4. PROJECTION OF D&I WATER DEMAND

##### 4.1 Assumptions

Domestic and industrial water demand is and will be attributable to following 3 uses in the Region: (1) Domestic including commercial and public, (2) Manufacturing, (3) Palm oil mill, rubber factory and pineapple factory.

- (1) Household, commercial and public water demands, which have significant correlation with the size of population and with location, urban area or rural area.
- (2) Water demand of manufacturing industries, which varies by commodities. The water demand of a manufacturing industry is almost in proportion to the output.
- (3) The water demands by agro-based factories such as palm oil mill, rubber factory and pineapple factory, which are usually located in the vicinity of plantations rather than in urban areas.

Water demand were projected for town and district.

The towns and districts defined in this Study are shown in Table 6.

Domestic water demand is assumed to be partly met by public supply systems and partly by private. In urban area, state PWD is responsible for public water supply. In rural area, both state PWD and RESP are responsible.

Part of manufacturing water demand is assumed to be supplied by state PWD and the rest to be supplied by private facilities.

All of the agro-based factories water demand are assumed to be supplied by private water supply system by direct abstraction of surface water and by private wells.

For PWD water supply, the following target was set to reduce UA ratio (unaccounted-for water ratio) for 1985 during the Senior Water Engineers' Conference.

Supply Area	UA Ratio (%)
-----	-----
Individual Supply District	less than 20
Individual State	less than 25
Overall % for Peninsular Malaysia	less than 20

However, the current UA ratio in Peninsular Malaysia and the State of Johor are considerably high (Table 7).

After an investigation and the discussion with State PWD, following assumption was adopted for each district for 2005.

District	UA ratio in 2005
-----	-----
Johor Bahru	20%
Pontian	25%
Kota Tinggi	25%
Kluang	20%
Mersing	25%

The assumed UA ratio for each district in 1983, 1985, 1990, 1995, 2000 are also shown in Table 8.

TP ratio (treatment plant water use ratio ) was assumed at 5% of the quantity of water abstracted at intake point.

Source demand (S.D.) is obtained as follows:

$$S.D. = C.D. / (1 - UA \text{ Ratio}) \times (1 - TP \text{ Ratio})$$

The UA ratio and TP ratio for water supply except by PWD were assumed nil since intake points and consumption points of water are closely located and the customer demand is considered to be equal to source demand.

#### 4.2 Projection of Domestic Water Demand

##### 4.2.1 Methodology

Domestic water demand for public supply (PWD and RESP water) was projected for towns and the rural areas in the Region. Customer Demand (C.D.) for treated water was obtained for each area as follows:

$$\text{Treated Water Demand (C.D.)} = \text{Population} \times \text{Service Factor} \times \text{PCDU (Per Capita Daily Use)}$$

Accordingly C.D. for private water was estimated for each area as follows:

$$\text{Private Water Demand} = \text{Population} \times (1 - \text{Service Factor}) \times \text{PCDU}$$

Source demand (S.D.) can be obtained based on C.D., UA ratio and TP ratio as stated in Section 4.1.

##### 4.2.2 Population projection

Population projection for towns and rural areas in 1983, 1985, 1990, 1995, 2000 and 2005 were made and the results for the Region were given in Annex A (Socio-economy) which are also shown in Tables 9 to 10 in this Annex.

##### 4.2.3 Projection of service factor

The 1980's is the United Nations Water and Sanitation decade and it is proclaimed that all the inhabitants be served water by public systems and sewerage systems by 1990.

In this respect and after discussions with state PWD and MOH and considering the present service factor, future service factor was assumed by district and urban-rural as shown in Tables 11 and 12.

#### 4.2.4 Projection of per capita daily use

Per capita daily water use in Peninsular Malaysia including the Region was projected applying its correlation with per capita GDP observed in some countries based on the data given in Tables 13 and 14. Projected per capita daily use for urban and rural area thus estimated is shown in Table 15.

Per capita daily use for private domestic use was assumed at 40 liters up to 2005.

#### 4.2.5 Projected served population

Based on the projected population and service factor, population to be served by public supply system, PWD and RESP, was estimated. During 1983-2005 period, served population in the region will grow at the average annual growth rate of 4.7% and  $1,554 \times 10^3$  population will be served by public systems in 2005.

Projected served population of public water in the Region are given in Tables 16 and 17.

#### 4.2.6 Projected domestic water demand

Source demand of the total domestic water demand will grow at the average annual growth rate of 6.3% during 1983-2005 period, reaching  $187.7 \times 10^6 \text{ m}^3/\text{y}$  (514 Mld) in 2005 in the Region. Around 86% thereof will be incurred in urban area and the rest in rural area. The total domestic water demand will account for 48% of the total demand in 2005.

Domestic water demand for public supply was projected to grow rapidly reflecting the following increases:

- (1) Population increase;
- (2) Rise of urbanization ratio;
- (3) Improvement of service factor; and
- (4) increase of per capita daily use.

Total domestic water demand for public supply will grow at the average annual growth rate of 6.6% during the period from 1983 to 2005. In 2005, domestic water demand will almost fully be met by public supply systems, namely 99% or  $186.4 \times 10^6 \text{ m}^3/\text{y}$  (511 Mld) will be supplied by PWD and 0.6% or  $1.1 \times 10^6 \text{ m}^3/\text{y}$  (3 Mld) by RESP.

Projected domestic water demand is given in Tables 20 to 25.

#### 4.3 Projection of Manufacturing Water Demand

##### 4.3.1 Methodology

Manufacturing water demand was projected for the Region in 1983, 1985, 1990, 1995, 2000 and 2005 based on the gross output values of manufacturing industries and net unit manufacturing water use (NUIW) for producing unit gross output value for each commodity, considering the availability and reliability of the data which may be utilized for manufacturing water demand projection.

Manufacturing (M) water demand in terms of C.D. will be obtained as the sum of water demand of each commodity that is obtained as the product of gross output value and NUIW. S.D. of manufacturing water is obtained as follows:

$$\text{S.D.} = \text{C.D.} / (1 - \text{UA Ratio}) \times (1 - \text{TP Ratio})$$

The methodology is explained further in the subsequent sections.

#### 4.3.2 Projection of gross output value of manufacturing sector

Gross output value of the State of Johor in 1983, 1985, 1990, 1995, 2000 and 2005 has been projected in Annex A (Socio-Economic Study).

It was assumed in this Study that all of production of the manufacturing sector will be born in urban area except agro-based industries.

#### 4.3.3 Net unit industrial water use

Manufacturing water use was estimated based on NUIW by industrial classification, excluding the recyclic water use.

Industrial classification was determined based on the current Malaysian Industrial Classification as well as Japanese Industrial Classification as same with Annex A.

NUIW declines as the recyclic water use develops. The industrial water use data of Japan from 1960 to 1983 show that the NUIW has dropped sharply until 1980 and then remained almost constant after 1980 while gross unit water use including recycling water has not shown significant change after 1970. During the period of 1985 to 2005, manufacturing industries in Peninsular Malaysia are expected to make sharp growth, accompanying the modernization of manufacturing technology including water use. It was, therefore, assumed that NUIW in Peninsular Malaysia including the State of Johor in 2000 will reach the values of Japan in 1983 and keep constant until 2005. The projected NUIW is shown in Table 18.

#### 4.3.4 Projection of manufacturing water demand in the Region

As stated in Section 4.3.1, manufacturing water demand in terms of C.D. in the State of Johor will be obtained multiplying gross output value with NUIW.

Out of total manufacturing water demand, water demands of agro-based factories water demand such as palm oil mills, rubber and pineapple factories which are estimated in Annex C (Agriculture and Irrigation Development) was located in rural area. Other water demand was assumed to be located at towns such as Johor Bahru and industrial estates.

SEDC has the estimation of present water demand of each industrial estate and future development plan, which shows only Pasir Gudang Industrial Estate will have some water demand and the others will be negligible. Therefore, the water demand of Pasir Gudang Industrial Estate was taken into account with the projected figure of "Pasir Gudang Development: Master Plan for Infrastructure Services" (Table 19).

Then manufacturing water demand less water demands of agro-based factories and Pasir Gudang was allocated to each town in proportion to the population sizes.

#### 4.3.5 Projected manufacturing water demand

Manufacturing water demand of the Region was projected to rise sharply due to the rapid growth of manufacturing industries.

Source demand of total manufacturing water demand will grow at the average annual growth rate of 6.8% during 1983-2005 period, reaching  $204.9 \times 10^6 \text{ m}^3/\text{y}$  (561 Mld) in 2005, of which 93% will be attributable to demand in urban area and the rest in rural area. The public supply system will supply 90% of the total manufacturing water demand. The rest, 10%, will be met by private facilities.

Projected manufacturing water demand is given in Tables 20 to 25.

#### 4.4 Projected D&I Water Demand

Total D&I water demand was projected to rise due to the combined effect of i) population increase, ii) service factor improvement, iii) per capita consumption increase, and iv) growth of manufacturing industries.

Source demand of total D&I water demand will grow at the average annual growth rate of 6.5% during 1983-2005 period, reaching  $397.2 \times 10^6 \text{ m}^3/\text{y}$  (239 Mgd) in 2005. About 88% thereof will be occurred in urban area and the rest in rural area.

Total D&I water demand for public supply will grow at the average annual growth rate of 7.2% during the same period, reaching  $366.0 \times 10^6 \text{ m}^3/\text{y}$  (220 Mgd) in 2005. About 93% thereof will be incurred by the water demand in urban area and the rest in rural area. In 2005, about 92% of the total D&I water demand will be met by public systems.

Total D&I water demand in 1983, 1985, 1990, 1995, 2000 and 2005 are given in Tables 20 to 25.

#### 4.5 Projected D&I Water Abstraction at River Intakes

All the D&I water demand projected were allocated and loaded on the existing and proposed intakes with due regard to the existing water supply networks.

The allocations of water demand were summarized in Table 26.

#### 4.6 Water Supply to Singapore

The present water abstraction by Singapore is deemed to have reached full scale with regard to the water resources potential at Gunong Pulai, Skudai and Tebrau intake sites. And it is presumed that no future extension of intake facilities is conceivable for these

intake sites. With this accord, the present volume of abstraction for each intake mentioned above is assumed to be kept constant upto 2005.

For Johor river, present abstraction by Singapore at Kota tinggi is  $4.7 \text{ m}^3/\text{sec}$  or 90 Mgd which is controlled by the installed capacity of the treatment plant. The capacity of pipeline is  $6.3 \text{ m}^3/\text{sec}$  or 120 Mgd. Further extension of capacity by  $2.1 \text{ m}^3/\text{sec}$  or 40 Mgd is under design aiming to secure an abstraction capacity of  $8.4 \text{ m}^3/\text{sec}$  or 160 Mgd.

So far, the future amount of abstraction from the Johor river by Singapore is not projected but assumed arbitrarily that the abstraction will reach 160 Mgd in year 1990. For this preliminary study stage, two different cases are assumed for the abstractions after 1990. That is:

Case 1: Abstraction amount will reach 250 Mgd in year 1995 after it reaches 160 Mgd in 1990. After 1995 it will be kept constant, 250 Mgd, upto 2005.

Case 2: Abstraction will reach 160 Mgd in year 1990 and after that it will be kept constant, 160 Mgd, up to 2005.

The demand for the years between 1985 and 1990 for both cases and ones for the years between 1990 and 1995 were interporated by the figures estimated in proportion to the whole water demand of Singapore. The water demands by Singapore to be abstracted from the Johor river are presented in Table 27 for both case.

It is noted that the projected abstraction volume includes the treated water supply to PWD which is assumed to be  $40 \times 10^6 \text{ m}^3/\text{y}$  (110 Mld) constantly from 1985 to 2005.

6. Variation of Crop Coefficient with Growing Stage

## 1. INTRODUCTION

The objective of agriculture and irrigation development is to estimate the water demand in both sectors up to year 2005. For this purpose, information and data concerning land use, crop cultivation, future development plan, were collected at offices and corporations concerned. Interview surveys were also conducted in plantations and fields. Discussions with officials were effective.

## 2. BACKGROUND OF AGRICULTURE

### 2.1 Role of Agriculture

Agriculture is one of the largest sectors which have sustained the national economy. Although the contribution of the agricultural sector to the national economy has been decreasing gradually in recent years because of the structural change in the Malaysian economy, this sector in 1983 accounts for M\$7,030 x 10<sup>6</sup> in 1970 constant prices or 22.4% of GDP. It absorbed 1.94 x 10<sup>6</sup> workers or 37.0% of the total employment and entailed M\$10,961 x 10<sup>6</sup> in 1983 constant prices or 33% of the gross export.

The growth rate of GDP in the agricultural sector during the first three years of Fourth Malaysia Plan (4MP, 1981-85) attained to 4.0% per annum exceeding the target growth rate of 3.0% per annum under 4MP. This is due mainly to the notable increase in palm oil production. In the Mid-term Review of 4MP, therefore, the average growth rate of the agricultural sector is swelled to 4.2% per annum.

### 2.2 Organization Responsible for Agriculture Development

Ministry of Agriculture, Ministry of Land and Regional Development and Ministry of Primary Industry are the responsible agencies for agricultural development. The Ministry of Agriculture is responsible for (1) all crop production except for export crops, (2) fish and livestock production, (3) agricultural credit, marketing and research except for rubber and oil palm, and (4) farmer's organizations, community and cooperative development. The Ministry of Lands and Regional Development performs the duties of land development and rehabilitation. The Ministry of Primary Industry handles export crops.

schemes, while the Department of Agriculture is responsible for agricultural extension services.

Under the Ministry of Lands and Regional Development, there are three nationwide authorities; Federal Land Development Authority (FELDA), Federal Land Consolidation and Rehabilitation Authority (FELCRA) and Rubber Industry Smallholders Development Authority (RISDA). FELDA develops new land and distribute the developed land to eligible person. FELCRA is responsible for rehabilitation of unsuccessful state land schemes and for development of new land schemes at a smaller scale than FELDA's schemes. RISDA is responsible for encouraging rubber smallholders to replant the existing non-productive rubber trees with high-yielding varieties or other crops, to extend rubber planting areas and to obtain shares in RISDA block plantings run on an estate basis.

### 3. PRESENT STATUS OF AGRICULTURAL PRODUCTION IN THE REGION

#### 3.1 Soils

Soils in the Region are broadly classified into (1) alluvial soils extending over coastal plains, riverine flood plains and riverine terraces, (2) sedimentary soils occurring on undulating plains, rolling hills and mountainous area, and (3) soils of urban and mined land.

Based on the soil map prepared by MOA, covering area for each soil in the Region is estimated at 2,814 Km<sup>2</sup> for alluvial soils, 4,484 Km<sup>2</sup> for sedimentary soils and 52 Km<sup>2</sup> for soils of urban and mined land as shown in Table 1. Twenty of soil series are identified in the Region.

#### 3.2 Land Use

Department of Agriculture prepared a land use map in a scale of 1 to 126,720. The map shows the land use of the Region as of 1974 through interpretation of areal photographs with a scale of 1 : 25,000. The Department prepared another land use map as of 1981 in the same scale, revising the change in land use since 1974. This map has not been published yet, but it was made available to the Study. The information in the maps were confirmed by interviews and reconnaissance surveys conducted by the Study team. Various governmental offices and corporations concerned were interviewed to collect the information.

A general land use map of the Region as of 1981 covering 735,000 ha, is shown in Fig. 1. The Region includes main towns such as Johor Bahru, Kota Tinggi, Pontian Kechil, Senai, Kulai, Benut, Ulu Tiram and Masai. National road, public road and farm road are running in all directions, connecting main towns and rural centers. The international railway connecting Singapore and Bangkok is running from north to south through the Region.

Agricultural land of 395,702 ha occupying 54% of the whole Region comprises 167,967 ha of oil palm, 155,223 ha of rubber, 15,053 ha of coconut, 14,148 ha of pineapple, 9,155 ha of sugarcane and 34,156 ha of other crops including cocoa, banana, pepper, orchards, paddy, diversified crops and mixed horticulture. Forest of 228,275 ha (31%) mostly covers mountainous area in the north-eastern part of the Region. Swamps of 71,971 ha (10%) develop along coastal plains. Other areas of 39,232 ha (5%) are used for urban area, rural centers, estate compounds, mining, railway and roads.

Compared with the land use in 1974, agricultural land increased by 56,000 ha and non-agricultural land expanded by 30,000 ha. On the other hand, forest area reduced by 58,000 ha and swamps by 28,000 ha. In agricultural land, rubber decreased by 27,000 ha. Expansion of agricultural land is attribute largely to development of oil palm.

As for agricultural land use, the State DOA prepared the agricultural statistics as of 1983. The statistics shows the agricultural land use area of various crops by management sector. There exists a considerable difference regarding the area for sugarcane between this statistics and the interpretation of land use map. The statistics shows the existence of only about 10 ha of sugarcane land in the Region while the land use map indicates more than 9,000 ha. It is unnatural to consider that a sugarcane land of 9,000 ha was abandoned within the lapse of 2 years. This discrepancy should be solved in further study. Agricultural statistics shows the consistency to the land use map regarding agricultural land use except for sugarcane. The land use areas in the statistics were used for the estimation of the agricultural production after the confirmation through interview surveys.

### 3.3 Tree Crops Cultivation

As shown in the previous section, oil palm and rubber are the dominant crops in the Region. Based on the Agricultural Statistics in 1983 prepared by the State DOA, planting area of these crops are estimated at  $175 \times 10^3$  ha for oil palm and  $123 \times 10^3$  ha for rubber.

Other main tree crops are coconut ( $21.5 \times 10^3$  ha), pineapple ( $8.1 \times 10^3$  ha), cocoa ( $5.6 \times 10^3$  ha) and coffee ( $2.0 \times 10^3$  ha). They are cultivated by small-holders, estates and FELDA. The breakdown thereof are presented in Tables 2 to 7.

Productions in the Region in 1983 are estimated at  $3,345 \times 10^3$  tons as fresh fruit bunch (FFB) for oil palm and  $117 \times 10^3$  tons as dry rubber content (DRC) for rubber, applying present annual yield of FELDA schemes and present annual average yield of private estates and smallholders for both crops as shown in Table 8 and Table 9.

Pineapple production is estimated at  $177 \times 10^3$  tons as fresh fruit using an unit yield of 22.1 tons/ha estimated by the Western Johor Agricultural Development Project. Production of other crops are estimated at  $27.7 \times 10^3$  tons for coconut,  $4.5 \times 10^3$  tons for cocoa and  $7.9 \times 10^3$  tons for coffee, based on the average yield of each crop by district and by sector as shown in Tables 10 to 12.

Of these above tree crops, the harvests of oil palm, rubber and pineapple are preliminarily processed in factories located in vicinities of planting area. Those factories consume much water to process them. At present 24 of palm oil mills, 20 of rubber factories and 5 of pineapple cannery factories are in operation in the Region.

### 3.4 Rice Cultivation

In the Region, only 2 irrigation schemes for paddy cultivation have been maintained by the State DID of Johor. The total irrigation area is 255 ha. Location of these schemes is shown in Fig. 3. The Lukut scheme of 78 ha is a single paddy cropping area due to water shortage during dry season and is owned by 106 farmers (0.74 ha per farmer). On the other hand, the Ulu Benut scheme of 177 ha is a double cropping area owned by 436 farmers (0.41 ha per farmer). The unit paddy yield in these schemes has been fluctuating between 0.9 and 2.7 tons per ha mainly using Madu Tiga (3X) variety with growing period of 130 days. Most paddy farmers in the Region are working in

oil palm or rubber estates to make a livelihood according to interview to farmers. The feature of these schemes is shown in Table 22.
