#### PREFACE

It is with great pleasure that I present to the Government of Republic of the Philippines this report entitled the Panay River Basinwide Plood Control Study.

This report embodies the result of a survey which was carried out from August 1983 to November 1985 for the formulation of basin development plan placing emphasis on the flood control plan by a study team commissioned by the Japan International Cooperation Agency following the request of the Government of Philippines to the Government of Japan.

The study team, headed by Mr. Hirosuke Takahashi, had a series of discussions with the officials concerned of the Government of Philippines and conducted a wide scope of survey and data analyses.

I sincerely hope that this report will be useful as a basic reference for development of the Panay river basin as well as the country.

I wish to express my deep appreciation to the officials concerned of the Government of Philippines for their close cooperation extended to the study team.

November 1985

Keisuke Arita President Japan International Cooperation Agency Tokyo, Japan

#### LETTER OF TRANSMITTAL

November, 1985

Mr. Keisuke Arita President, Japan International Cooperation Agency, Tokyo, Japan

Dear Sir,

We have the pleasure of submitting herewith the Final Report on the Panay River Basin-wide Plood Control Study.

For preparation of this report, field investigation and studies were made for about two years starting from August, 1983. The intermediate results of the studies were compiled into a series of reports and submitted to your Agency on schedule. During October 3 and October 12 of 1985, the survey team visited the Philippines again and had the meetings to discuss about the Draft Final Report with the officials of Philippine Government concerned. All the findings and comments obtained in the meetings have been fully incorporated in this Final Report.

The engineering and socio-economic studies of the Report on the level of Master Plan recommend some projects which are technically sound and economically feasible. It is our sincere hope that the projects will be proceeded to the next stage of study for the early realization of the project as soon as possible along the recommendations presented in this Report.

In submitting this report, we wish to express our sincere appreciation and gratitude to the personnel at your Agency, the Japanese Embassy in the Philippines, and the authorities concerned of the Government of Philippines represented by the Ministry of Public Works and Highways for the constant support and cooperation extended to us during our field survey as well as home office work.

Very truly yours,

Hirosuké Takahashi Team Leader Panay River Basin-wide Plood Control Study (Nippon Koei Co., Ltd.)

#### Notes

 The currency equivalents applicable to this report are :

US\$ 1 = Peso (P) 18 = Yen (Y) 234.

 Construction cost estimates in this Study are expressed in financial costs at mid-1984 price levels.

SUMMARY OF PROPOSED DEVELOPMENT PROJECTS

#### 1. Outlines of Proposed Development Projects

The purpose and timing of implementation of the proposed development projects can be outlined as follows:

#### 1.1 Flood Control Project

(1) 1st Stage work (Short-term provisional plan)

#### River improvement

River improvements for this stage would comprise the following:

- (a) Cogon bypass floodway (9.5 km): This plan would provide for a bypass floodway from 4 km downstream of Panitan to the mouth of the Hamulauon river. Flood flow exceeding the bankful capacity of the Pontevedra river of 500 m<sup>3</sup>/sec would be diverted by this floodway.
- (b) River improvement of the Pontevedra river (6.1 km): This would provide partial improvement of the Pontevedra river from the entrance to the floodway to Pontevedra town. The channel section, where the carrying capacity is less than 500  $m^3/sec$ , would be widened and eroded banks would be revetted.

 (c) The stretch between Panitan and Cogon floodway entrance (6.5 km): The low flow capacity of the river would be expanded by improvement of the existing river channel. Levees would be constructed on the both banks.

s - 1

By this improvement work, the areas downstream of Panitan town (including the Panitan - Panay irrigation area) would be relieved of flood damages caused by floods of less than 10-year recurrence.

#### Polder dykes

Polder dykes would be embanked to alleviate flood damages at 4 towns/villages with high flood damage potentiality, i.e. Dao, Cuartero, Mambusao and Sigma.

#### Multipurpose dam

The Panay B dam would be constructed to reduce flood flows downstream of the dam. The dam is conceived as a multipurpose dam with a power station equipped with 7,100 kW generating facilities.

#### Non-structural measures

(a) Flood plain management

In areas upstream of Panitan (flood vulnerable area 220 km<sup>2</sup>), where flood control projects by structural measures will not be carried out for the time being, development should be regulated to avoid any increase in the risks of future flood damage. For areas downstream of Panitan too (flood vulnerable area 118 km<sup>2</sup>), appropriate guidelines for development will have to be set since the proposed Short-term Plan will only give protection against a 10-year flood.

s - 2

#### (b) Relocation of housing

Relocation of housing is initially proposed for two sub-areas; (i) the lower reaches of the Maayon river (sub-area Y1) and (ii) the middle reaches of the Mambusao river (sub-area M3, but excluding Mambusao town). Actual implementation should however be subject to further detailed survey to be included in the feasibility investigations in which the practicality of the plan would be examined on the basis of each building.

#### Flood forecasting and warning system

Advance information on incipient floods will be indispensable for efficient operation of structural and non-structural measures proposed herein. Flood forecasting by a stage-correlation technique is proposed as a provisional step. This would be replaced later by telemetered facilities. (See Figure 4-5 of main text for location of the proposed facilities.)

#### (2) 2nd Stage work

#### River improvement

At this stage, the bankful capacity of the river channels would be increased (design discharge: a 25year flood) in the stretches downstream of Panitan which would have been already improved under the 1st Stage Project. 16.0 km would be so improved including the Cogon floodway.

#### Polder dykes

Polder dykes would also be constructed at 3 towns/villages, i.e. Maayon, Jamindan and Dumarao.

(3) 3rd Stage work

The 3rd Stage works would protect almost all the flood vulnerable areas and thus raise the protection level up to the 100-year flood. The protective work would include:

(a) Enlargement of bankful capacity of channels improved in 2nd Stage (16.0 km):

This would raise the bankful capacity to accommodate a 100-year flood for the stretches improved in the preceding 2nd Stage work.

(b) Improvement of upstream reaches of main and tributary rivers (93.4 km):
Improvement work would be initiated in this stage for the river stretches previously left unimproved, i.e. (i) middle and upstream reaches of the Panay, (ii) lower reaches of the Maayon and (iii) lower reaches of the Mambusao river.

#### 1.2 Irrigation Development

Panitan - Panay Irrigation Project

This plan would bring a total area of 3,250 ha under irrigation, by integrating the existing sporadic PIS's into one. The target yield was set at 5.0 ton/ha (paddy). A constraint inherent in the proposed development area is that the itself area is prone to flooding. Therefore flood control project in (1) above should precede implementation of the irrigation project.

s - 4

#### Mambusao Irrigation Project

This project would aim to rehabilitate existing irrigation facilities and to expand arable areas along the lower reaches of the Mambusao river. The project covers an area of 2,145 ha in total. Like the Panitan - Panay irrigation area, this irrigation project is also located in a floodprone area. However, evaluation revealed that the project would be feasible without providing specific measure for flood protection.

#### 1.3 Roxas City Water Supply Plan

The Roxas City municipal and industrial water supply project proposed herein, has the following two objectives:

- (a) The existing water supply facility suffers from contamination by sea water. The primary objective of this project would therefore be to solve this problem, by diverting the streamflow of the main Panay river to provide a source of uncontaminated water.
- (b) The second objective would be to increase the capacity of existing facilities. The required water supply capacity in 1995 is projected to be 11,650 m<sup>3</sup>/day, while the present supply capacity is 4,200 m<sup>3</sup>/day. The proposed intake and transmission facilities would make available an additional 7,450 m<sup>3</sup> of water a day.

Due to the urgency of item (a), the work should be given priority for its early implementation.

S - 5

#### 1.4 Hydropower Generation Plan

The Panay B dam, which would be proposed as part of the 1st Stage work of the flood control project, could be completed by 1994. The power supply and demand balance indicates that the Panay Grid will be faced with a shortage in supply capacity around 1995. This would justify the commissioning of the Panay B power station by that date. The electric power generated at the Panay B power station would be transmitted to the Panitan substation (138/69 kV) and thus feed the Panay Grid. The installed capacity of the Panay B power station would be 7,100 kW, and the annual energy production would amount to 31.4 GWh.

#### 2. Implementation Schedule

Selective staged implementation has been proposed for the flood control project; initially a 1st stage project, followed by 2nd and 3rd stage projects. The two latter would be realized when future damage potentials increase and the projects become economically viable (EIRR of more than 8%). The proposed implementation schedules, including those of other projects, are presented in the attached table.

#### 3. <u>Construction</u> Cost Estimate

The total construction cost of the above proposed projects was estimated to be  $P5,820 \times 10^6$  at 1984 prices. Breakdowns by project are presented in the attached table.

4

#### 4. <u>Economic Evaluation</u>

The economic viability of the proposed projects was evaluated based on costs and benefits assessed for each project. All the proposed schemes are deemed to be economically favourable projects, as represented by favorable economic indices (EIRR

S - 6

ranges from 8.1% to 25.7%). The results of evaluation are shown in the attached table.

#### 5. Summary of Recommendations

In view of the economic viability of the projects and increasing social needs in the basin, follow-up action should be taken to achieve early implementation of the proposed projects. The next-phase studies which should be started at the earliest opportunity are:

- (a) A Feasibility Study of the 1st Stage Flood Control Project, including river improvement work, polders, Panay B dam, non-structural measures and flood forecasting/warning system.
- (b) Detailed Design of Roxas City Water Supply Project
- (c) Feasibility Studies of Panitan- Panay and Mambusao Irrigation Projects

#### 1984 November Flood Photo No. 1 (taken on Nov. 6)

Typhoon "Undang" hit the Panay river basin on Nov. 5, 1984 and caused the flood with serious damage.

This picture shows the scene of submerged road connecting the two towns of Mambusao and Sigma and the surrounding paddy fields. The water is flooded from the Mambusao river located on the left side of this picture.

#### 1984 November Flood Photo No. 2 (taken on Nov. 8)

This picture shows a view of the submerged road connecting the two towns of Panay and Pontevedra and the surrounding paddy fields/ houses at Agbalo village. The water has overflowed from the Pontevedra river seen at the right side of this picture.

Ģ

## 1984 November Flood Photo No. 3 (taken on Nov. 7)

This picture shows the scene of submerged road connecting the two towns of Panay and Pontevedra. The JICA jeep seen in the picture had to give up going to the Pontevedra town on the way due to the deeper water depth and high flow velocity.

1984 November Flood Photo No. 4 (taken on Nov. 9)

This picture shows the paddy fields along the Pontevedra river which are still submerged even 4 days after the typhoon attack.

#### CHAPTER I. BACKGROUND

R

C

6

1.1 The Panay river basin suffers from flooding almost every year and flooding has long been a major constraint hampering economic development in the Panay basin area as well as hindering stabilization of the livelihood of inhabitants. The flood problem in the Panay river basin was given preliminary study in the "Nationwide Flood Control Study" carried out from 1979 through 1982 and which recommended the necessity of further detailed planning of flood control measures on the Panay river at a river basin study level. The urgency of this was reinforced when in November 1984 Typhoon Undang caused widespread inundation in the Panay river basin and inflicted heavy damage.

1.2 In response to a request from the Government of the Philippines, the Japan International Cooperation Agency (JICA) carried out the present study, "The Panay River Basin-wide Flood Control Study" (the Study), starting in August 1983. The objective of the Study was to formulate an integrated water resources development plan for the Panay river basin. The Study accordingly covers various aspects related to basin water resources development, including investigation of socio-economy, hydrology, and land use, planning for flood control, agricultural development, multipurpose dam and water supply. Particular emphasis has been placed on the flood control aspect in view of its importance in the framework of the basin development plan.

1.3 Prior to this Study, maps at 1 : 10,000 scale covering the areas along the Panay river and its tributaries were made available under a separate JICA project through supervision of the survey and mapping processes. These maps were essential for clarifying inundation areas, assessing flood damage and estimating work quantities of protective measures. In this context, the rearrangement of work schedule through the courtesy of the Government of the Philippines, which enabled use to be made of the maps in this Study, was of great significance in the timely completion of the Study.

# CHAPTER II. PROJECT AREA

## Panay River Basin

2.1 The Panay river drains an area of approximately 2,181 km<sup>2</sup>. The basin is located in the northeastern part of Panay island, covering almost the entire area of Capiz province. The location of the basin is shown in Figure 2-1. It includes a principal city (Roxas) and 12 municipalities with a total estimated basin population of 448,000 in 1980. The gross regional domestic product of the basin at 1972 constant prices was P917 x  $10^6$  in 1982 (\$2,950 x  $10^6$  at current price). The per capita GRDP of the basin was P1,766 at 1972 price in the same year (\$5,620 x  $10^6$  at current price). Projections of population and GRDP are respectively summarized in Tables 2-1 and 2-2.

ê

9

2.2 The climate of the basin falls in Type III of the Philippines climate classification and is characterized by no pronounced seasonal climatic variation, although it is relatively wet from May to October and dry from November to April. The average annual rainfall in the basin is 2,550 mm. Its areal distribution however varies from 3,500 mm in the western mountainous area to 2,000 mm in the southeastern area, as shown in the iso-hyetal map of the basin presented in Figure 2-2. The average annual total runoff of the Panay river is 2,920 x  $10^6$  m<sup>3</sup> at the bifurcation point of the Lower Panay river and the Pontevedra river. Its annual average discharge is 92.6 m<sup>3</sup>/sec.

2.3 The geology of the river basin was studied from the regional geological maps and by field investigation. The geological map of the river basin is presented in Figure 2-3. The groundwater potential of the basin was found to be limited especially in terms of water quality due chiefly to poor quality aquifers, intrusion of seawater and contamination by sewage.

2;

# Land Use

ſ

0

P

2.4 Land use in the basin is mainly for food production. Of the total basin area of 2,181 km<sup>2</sup>, 48,530 ha (21%) is used for sugarcane; 40,960 ha (19%) for paddy fields; and 10,560 ha (5%) for fishponds. The remaining 55% is occupied by sorub, orchards, pasture, grassland, marsh/swamp and others. The land use of the Panay river basin is summarized in Table 2-3, and illustrated in Figure 2-4.

# Agricultural Production

2.5 Rice is the main crop in the basin followed by sugarcane. Total annual production of paddy in the basin stands at about 215,000 tons. Double cropping is practiced in most of the existing irrigated and rainfed fields. The total annual production of sugarcane in the basin reaches about 60,000 tons on an average.

2.6 Present average yields of paddy are about 3.2 tons per ha for irrigated paddy and 2.8 tons per ha for rainfed paddy. The price of rice is controlled by the Government. In September 1984, the buying price of milled rice was 2.65 per kg. As the typical farmer has a paddy farm of 1.5 - 2.0 ha, a family of 7 to 8 members, and an annual income ranging from P16,000 to P19,500, if his annual expenditure is P15,500 to P18,500, his Capacity to Pay is P500 to P1,000.

### Flood Records

2.7 Floods in the basin are caused mainly by passing typhoons and by tropical depressions. According to the record, the basin was visited by 19 typhoons and 11 major tropical depressions during the 37 years from 1948 through 1984. Severe floods were experienced in November 1973, May 1976 and November 1984. The flood of 1973, caused by Typhoon Openg, was the largest on record and caused the loss of 18 human lives. The second largest was the Undang flood in 1984. The Undang flood induced an instantaneous peak discharge of 1,080 m3/sec at Cuartero, which is comparable to 1,420 m3/sec of the Openg. The area inundated by the flood

Undang is shown in Figure 2-5, and the flood flow profiles are shown in Figure 2-6.

Flood Analysis and Damage Estimate

2.8 A computerized river basin model was constructed, as shown schematically in Figure 2-7, to conduct flood flow analysis. The model was chiefly calibrated by the Undang flood records. Distribution of flood flow of representative probable floods is shown by river stretches in Figure 2-8. Estimated depths of inundation in the basin for the 5-, 25- and 100-year floods are shown in Figures 2-9 to 2-11. Estimated inundation areas flooded by the 5- and 100-year floods are shown in Figure 2-12.

2.9 Consequently, the areas likely to be inundated and population affected by floods of varying return periods were estimated through simulation of flood flow, as summarized in Table 2-5. Land at risk from a 100-year flood, denoted in this Study as the flood vulnerable area, was estimated to amount to 33,820 ha, or 16% of the basin area. The flood vulnerable area includes 18,944 ha of paddy fields, 3,849 ha of sugarcane fields and 1,137 ha of fish ponds. The flood vulnerable area is inhabited by residents numbering 121,300, or 27% of the basin population. Land use in the flood vulnerable area is illustrated in Figure 2-13 and summarized in Table 2-6 by sub-area. The sub-area divisions are shown in Figure 2-14.

2.10 The average annual loss caused by flood damages was estimated to be  $P105 \ge 10^6$ , mostly in respect of crops and buildings. Itemized flood damages for 1984 are summarized in Table 2-4.

# CHAPTER III. BASIC CONCEPTS OF BASIN DEVELOPMENT

(Flood Control Plan)

# Basic Concept

.

3.1 A flood control plan must be implemented through both structural and non-structural measures. For the safety of facilities and social benefits, it is always desirable to establish a high protection level (say against a 100-year flood) in designing structural measures, for instance, by river channel improvement and dyking. Such measures are not necessarily viable from an economic viewpoint, however, because of the heavy costs and in the present state of development in the objective region. It is proposed therefore that the flood control project should be implemented in stages, to match the growth of the region's economic activities. Accordingly a threshold EIRR value of 8% was adopted for judging economic viability.

3.2 To achieve this progressive development, flood control plans by structural measures were conceived for three different protection levels, namely: Long-term Plan (LP), Mid-term Plan (MP) and Short-term Provisional Plan (SP). The design floods and protection targets of the three planning phases are summarized below:

Basic	Development criteria for formulation	<u>1 01</u>
	Flood Control Projects	an a
Development Level Alternatives	Development Target	Protection Level (Design Flood)
LP : Long-term Plan	About 90% of the population1/	100-year flood
	to be relieved from flood hazard	
MP : Mid-term Plan	About 70% of the population	25-year flood
•	to be relieved from flood hazard	

5

Basic Development Criteria for Formulation of

(continued)

Development		Protection Level
Level Alternatives	Development Target	(Design Flood)
SP : Short-term	More than 50% of the population	2 to 10-year
Provisional	to be relieved from normal floods $\frac{2}{}$	flood
Plan		

Notes;  $\underline{1}/$ : Total population in the flood vulnerable area : 121,300  $\underline{2}/$ : With some damage reduction effect to be attained also in large floods.

## Proposed Protection Area - Structural Measures

3.3 The protection of areas with a potentially high risk of flood damage should receive priority. Figures 3-1 and 3-2 respectively illustrate the damage intensities caused by 5- and 100-year floods, and Table 3-1 shows damage potential by sub-area, in which priority protection areas are defined. Since protection work in a river stretch would naturally increase the discharge in the downstream reaches, there are other costs to be taken into consideration to preserve the position of areas with a relatively low damage potential, which should be used positively as natural retarding basins. Thus priority areas for protection must be selected carefully taking all factors into consideration including the provision of retarding basins.

3.4 Six flood protection area alternatives were considered as shown in Figures 3-3 to 3-5. The area conceived in Alternative-4 (See Figure 3-4) was eventually selected as the most practicable action area after comparison of numbers of people to benefit, the area of protected farmland and the cost-effectiveness of alternative plans (as illustrated in Figure 3-6). The action area, for which a long-term master plan was proposed, would include the stretches up to Dumalag along the Panay river and stretches along the Maayon and Mambusao rivers.

## Protection Measures

ſ

3.5 Protection measures fall into two categories, structural and nonstructural. Structural measures which would protect specific action areas would comprise:

化硫酸 化乙酸盐医乙酸盐医盐

- (a) River improvements
  - a-1) Improvement of existing river channels
  - a-2) Excavation of floodways (diversion channels)
- (b) Flood control dams
- (c) Combinations of (a) and (b)
- (d) Polder dykes

3.6 Non-structural measures would be considered mainly as a substitute for structural measures outside the protection action area. Some of the non-structural measures practicable in the Panay river basin would be as follows:

- (a) Flood plain management
- (b) Structural changes to buildings
- (c) Relocation of housing
- (d) A flood forecasting and warning system

A more comprehensive list of non-structural measures is given in Table 3-2, with comments on their applicability to the Panay river basin.

(Irrigation, Municipal Water Supply and Hydropower Development)

3.7 Water resources of the Panay river are abundant in relation to the demand for present water uses in the basin area. There are therefore great opportunities for effective development of water resources in the basin. Thus the possibilities of irrigation development, improved municipal water supply and hydropower generation have also been assessed in the Study, as part of the comprehensive water resources development plan.

6. Sp. 41

CONTRACTOR AND A

# CHAPTER IV. FORMULATION OF SPECIFIC DEVELOPMENT PLAN

#### (Flood Control Plan)

4.1 The flood control plan conceived in this Study would comprise plans at three protection levels as set out in Paragraph 3.2. The approaches to achieve each protection level would include both structural and nonstructural measures. The procedures used in selecting the recommended plan are shown in Figure 4-1.

1

Ę

### Structural Measures

## Long term Plan (LP)

4.2 The Long-term Master Plan (LP) was conceived as an ultimate overall framework of flood control measures, to provide the maximum protection under full development in the future. The planned protection at the LP level was assumed to relieve 90% of the affected population from flood damage and save farmland to the maximum degree practical in the event of a 100-year flood. The LP action area is presented in Figure 3-4 (Alternative-4).

4.3 The facility plan to achieve the above LP protection level was selected by economic comparison of alternatives including river improvement plans, bypass floodways, multipurpose dam plans and combinations thereof. The location of bypass floodways and dam plans examined in the Study are shown in Figures 4-2 and 4-3 respectively. The LP facility plan finally selected would comprise river improvement for the action stretches selected in Paragraph 3.4 above (total length 115 km), a bypass floodway at Cogon and a multipurpose dam development at Panay B site.

4.4 Economic evaluation for the selected LP facility plan revealed that the Long-term Plan, which would involve large-scale construction work and an EIRR of 4.5%, would not be economically justifiable under present

conditions. Nevertheless, since the economic activity in the Panay river basin was expected to increase in the future, it was tentatively considered that implementation of Long-term Plan would become economically viable around the year 2020 (commencement of the work).

Mid tora Plan (MP)

ß

0

P

4.5 The Mid-term Plan (MP) for flood control was formulated to provide an interim protection level, with the target of relieving about 70% of the affected population from risk of damage from a 25-year flood. The proposed facility plan would include improvement of 72.6 km of the Panay, Mambusao and Pontevedra rivers. The action area of MP would almost correspond to Protection Area Alternative-3 as presented in Figure 3-4. Economic evaluation revealed, however, that implementation of MP with an EIRR estimated at 6.7% would not be justifiable under the current economic conditions. It was tentatively considered that MP should be left in abeyance until around the year 2020 (commencement of the work). This implementation timing is similar to that assessed for the LP (See 4.4 above), thus there would be no specific merit of implementation of MP ahead of LP.

4.6 A further study on MP attempted to identify selective development works which would be worthy of earlier implementation. As its outcome, recommended were the enlargement of river channel to a 25-year flood capacity in the stretches downstream from Panitan and the construction of 3 additional polders in addition to 4 polders to be included in the SP (See 4.7 below). Accordingly these selective development works were deemed to constitute the mid-term implementation plan instead of the plan described in 4.5 above, but the target set out originally (relief of about 70% population) had to be disregarded.

Short term Provisional Plan (SP)

4.7 The Short-term Plan (SP) would provide some immediate relief from the risks of flood damage responsive to the most urgent needs for protection and justifiable in terms of economic viability. The proposed flood control projects for the Short-term Plan would include improvement of the river stretches downstream from Panitan town including the Cogon floodway, against 10-year flood, construction of polder dykes around 4 towns and construction of Panay B dam. The location of towns selected for polder plans is shown in Figure 4-4.

4.8 The EIRR value of the selected flood control projects for SP was assessed to be 11.4%, which indicates that the implementation of SP would be economically justifiable under present conditions.

## Non-structural Measures

4.9 In this Study, two particular non-structural measures were considered to be applicable to the Panay river basin:

6

## Flood plain management:

The objective flood plain management would be to restrain future growth of damage potential within the areas prone to flooding by means of regulations and administrative guidelines. Specific measures would cover 1) designation of flood vulnerable areas by ranks of damage frequency and grades of risk, 2) management of development within the flood vulnerable area and 3) information and education of residents.

Relocation of housing:

In place of devising measures to protect certain areas from flooding, it will be more economical to have the inhabitants relocated from their original settlements, to reducing the value of flood damage.

4.10 Based on preliminary estimation of cost and benefits of specific measures in the sub-areas, flood plain management and relocation of housing were proposed for the whole basin area, and in two sub-areas respectively.

# Flood Forecasting and Warning System

200

ß

4.11 The flood forecasting and warning system would be effective in reducing the damage to property and human lives, by providing information of floods at an early stage in their development. An economic evaluation was made of a telemeter system, and the EIRR value was assessed as 4.5%. Notwithstanding a relatively low economic return, since the early warning of a flood event is an indispensable element in successful operation of flood control measures, both structural and non-structural, implementation of a flood forecasting and warning system was positively recommended in this Study.

4.12 In order to obtain operational knowledge of flood runoff characteristics and correlation of flood levels, it is proposed as a first-step that staff gauges should be installed on the upper reaches of the Panay river and its tributaries, these will be replaced by a comprehensive telemeter system after the necessary operational experience has been gained as proposed above. The proposed facilities for the flood forecasting and warning system are shown in Figure 4-5.

#### Formulation of Flood Control Plan

4.13 Based on the considerations stated in paragraphs 4.2 to 4.11 above, the specific projects selected for implementation respectively for the Long-, Mid- and Short-term Plans were as given in Table 4-1 and as summarized below:

Proposed Project	Long-term	Mid-term	Short-term
Design flood	Plan (LP) 100-year	Plan (MP) 25-year	Plan (SP) 10-year
Facility plan			
River improvement work	115.5 km	22.1 km	22.1 km

Proposed Flood Control Projects of Long-, Mid- and Short-term Plans

(continued)

Long-term Plan (LP)	Mid-term Plan (MP)	Short-term Plan (SP)
*	*	an g <b>≭</b> ar an
_	7 towns	4 towns
*	×	<b>≭</b> , ≞
¥	×	*
	<u>Plan (LP)</u> * - *	<u>Plan (LP) Plan (MP)</u> * * - 7 towns * *

Notes: \* Contemplated - Not contemplated

4.14 As stated in Paragraph 3.1 above, the flood control project should be implemented in stages. The three protection levels, namely LP, MP and SP, are conceived as consecutive implementation stages.

Implementation Stage	Proposed Project
1st Stage Work	Implementation of Short-term Provisional Plan
2nd Stage Work	Upgrading to Mid-term Plan level
3rd Stage Work	Upgrading to Long-term Plan level

### (Irrigation Development Plan)

4.15 Agricultural production is the largest provider of employment in the Panay river basin but development of the basin is constrained by the limited areas of arable land and the still relatively low unit yields of rice. The irrigation development plan aims to extend technical irrigation to new irrigable areas and to rehabilitate the existing systems.

4.16 Potential irrigable areas in the basin were delineated at 10 locations, with a total area of 11,700 ha, of which 5,640 ha (48%) are already under irrigation. Amongst the above, the Panitan - Panay and the Mambusao areas were selected as appropriate for development as national irrigation systems (NIS). The proposed irrigation areas cover 3,250 ha and 2,145 ha respectively. The Panitan - Panay area is proposed as a new scheme by integrating the numerous existing pump irrigation systems

(PIS), which are dispersed in the area. The Mambusao area is proposed to rehabilitate and extend the existing irrigation facilities. The general plans of the Panitan - Panay and Mambusao irrigation areas are respectively shown in Figures 4-6 and 4-7.

Ũ

0

 $\mathbf{I}$ 

4.17 Paddy was selected as the main crop for cultivation in the new development areas. Yields of 5.0 tons per hectare are anticipated for both wet season and dry season paddies under proposed irrigation systems. Irrigation water for the Panitan - Panay area would be taken from the main Panay river by pumping and for the Mambusao area from the Mambusao river by gravity.

4.18 The total construction cost of the Panitan - Panay scheme was estimated to be P183 x  $10^6$  and of the Mambusao scheme to be P79 x  $10^6$ . The annual operation and maintenance cost was estimated to be P6.0x  $10^6$  for the Panitan-Panay scheme and P1.4 x  $10^6$  for the Mambusao scheme.

4.19 The economic viability of the both irrigation schemes will depend on the flood control measures to be devised in the proposed irrigation areas. If flood damages caused by floods of less than 10-year recurrence are eliminated, the EIRR value of Panitan - Panay area would be 11.7%, while the EIRR of the Mambusao scheme would be as high as 12.3% even without the provision of flood protection work. If the areas could be improved to be flood-free (100-year flood protection), the EIRR values would be 12.8% and 17.8%, respectively. It was concluded that the both irrigations projects would be economically viable.

## (Water Supply Plan)

计算法编辑 医胆管炎 医单子白髓

4.20 Notwithstanding improvement work undertaken in 1976, the Roxas City Water District (ROX-WD) still has unsolved problems with its water supply system. The most serious problem that awaits solution is the intrusion of sea water at the water intake site on the Lower Panay river during high tides in dry seasons.

4.21 The water demand of the Roxas City Water District in 1995 is

projected to reach 7,765 m3/day, which will need a waterworks supply capacity of 11,650 m3/day if 16-hour supply is adopted, whereas the present supply capacity is only 4,200 m3/day. The second requirement of the proposed ROX-WD supply system, therefore, is an increase in the supply capability to the required supply capacity level of 1995 by adding new pumping and conveyance facilities of 7,450 m3/day.

4.22 After a study of possible alternative plans, an improvement plan for the ROX-WD is proposed in this report on the basis of the following two measures:

 Construction of a water intake on the Main Panay river and excavation of the upstream reach of the Lower Panay river to El.
 -1.0 m to permit gravitational inflow of about 2.0 m3/sec from the main Panay river, and

Ĉ

読い

. Construction of a tidal gate 6 km downstream of the existing pumping station to prevent intrusion of sea water into the Lower Panay river.

The total construction cost of the proposed improvement plan was estimated to be  $P56 \times 10^6$  on a financial cost basis. A general plan of the proposed ROX-WD Improvement project is shown in Figure 4-8.

4.23 Economic evaluation indicated that the proposed ROX-WD Improvement project would be highly efficient economically, with an estimated EIRR value of 16.9%

#### (Hydropower Generation Plan)

4.24 The electric power supply in Panay island is still elementary. Household connections account for only about 36% of the potential users, with a relatively low consumption level of about 272 kWh p.a. per connected household.

4.25 According to the demand projection employed for this Study, as

shown in Table 4-2, the system peak demand of the Panay Grid will double in 12 years, from 41 MW in 1984 to 84 MW in 1996. On the supply side, the dependable output of the Panay Grid will grow from the present 41 MW to 75 MW by 1989, by the commissioning of new diesel plants at Dingle and Power Barge Stations. The balance, as shown in Figure 4-9, is suggestive of the need for a new power source in 1995. In this context, possibility of hydropower generation was assessed in relation to storage development proposed as part of the flood control plan.

£

ſ

4.26 Panay B dam was planned and optimized as a multipurpose dam, serving flood control and hydropower generation. It would be a 52 m high concrete gravity dam of 96 x 106 m3 in gross storage with an installed capacity of 7,100 kW, and would generate about 31.4 GWh of electric energy annually. The total construction cost would be about  $P471 \times 10^6$ . A general plan of the proposed Panay B dam is shown in Figure 4-10.

4.27 Economic evaluation indicated that the Panay B dam would be economically justifiable as a multipurpose project with an EIRR value estimated to be 11.2%.

## CHAPTER V. BASIN DEVELOPMENT PROGRAM

# Proposed Development Project

5.1 Development projects identified in Chapter IV comprise a series of flood control plans including one multipurpose dam scheme which would be implemented stage-wise, two irrigation projects and one water supply project. Items and proposed phasing of the proposed projects are summarized below. Stagewise implementation of flood control projects are as shown in Figures 5-1 to 5-3.

5.2 The outline and purpose of each project were presented in Chapter IV and also in the summarized descriptions given in the "Summary" at the beginning of this report. The detailed features of the proposed project are contained in Table 5-1.

# Implementation Schedule

R

5.3 A proposed implementation schedule is presented as "the Master Schedule" in Figure 5-4. The scheduling is based on the following considerations:

. In view of their high economic viabilities and social needs, the Flood Control Project - 1st Stage and ROX-WD Water Supply Project should be started at the earliest opportunity.

- Flood Control Project 2nd and 3rd Stage works would be implemented when future damage potentials increase and the projects become economically viable (EIRR of more than 8%). The Study revealed that these projects would become economically viable if the implementations start around 2010 for the 2nd Stage Project and 2020 for the 3rd Stage Project.
- . The Panitan-Panay Irrigation Project would be completed after the 1st Stage Flood Control Project is realized in its areas. As the Mambusao Irrigation Project would have a high economic viability even without provision of flood protection works in the area, its implementation could be advanced.

# Construction Cost Estimate

5.4 The total construction cost of the above proposed projects was estimated to be  $P5,820 \times 10^6$  at 1984 prices. Breakdowns by project are given on the next page.

## Economic Evaluation

5.5 Flood control benefits were considered to accrue from damage reductions to be realized by the project and taking into account future increases in damage potential. Irrigation benefits were defined as the incremental economic value of net production between "with-Project" and "Without-project" conditions. Benefits of the water supply project were assessed on the beneficial value of water, incremental value of lands in the service area, health benefits and reduction in fire damages.

5.6 The economic viability of the proposed projects was thus evaluated from the estimated costs and benefits. The results are shown on the next page. In the evaluation, the 2nd and 3rd stage flood control projects were assumed to be implemented in line with principles described in paragraph 5.3 above. The high EIRR evaluated for the 3rd stage project (15.2%) is due to inclusion of benefits from year 2031 onward which had previously been provided by polder facilities and pumped drainage will no longer be required once the 3rd stage project is completed in 2030 and therefore the benefits thereof would be taken over by the 3rd stage project.

## CHAPTER VI. RECOMMENDATIONS

6.1 The economic evaluation of the proposed program of works revealed high economic viability of all the proposed projects. Amongst these, the projects proposed for immediate implementation with priority with respect to both economic viability and compliance with social needs will be (i) Flood Control - 1st Stage (incl. polder plans and Panay B multipurpose dam) and (ii) ROX-WD Water Supply Project. For both of the above projects, the next-phase studies should be started immediately. The studies required, and which should be carried out simultaneously, will be as follows:

Flood Control Project: Feasibility Study (F/S) of the 1st stage development plan including river improvement, polders, Panay B hydropower development, non-structural measures and flood forecasting/warning system.

ROX-WD Water Supply: Detailed design including overall review and updating of the present study.

Panitan-Panay and Mambusao Irrigation Projects: Feasibility study for both projects, wherein the study of the Panitan-Panay scheme should take into account the flood control project to be provided in the area.

6.2 Although this Study recommends that the 2nd and 3rd Stages of the Flood Control Project should be left in abeyance until the future damage potential reaches a level that would provide an EIRR value in excess of 8% p.a., consideration should be given to earlier implementation if economic circumstances and government policies permit, since they would have important social and regional developmental benefits.

6.3 It should be noted that the peak flood flows are not fixed values, but are liable to change in accordance with the land use and the retardation effects of the upstream areas. In this context, the possibilities of developing flood control storages at dam sites discarded in this Study, such as the Panay C, Badbaran A and Mambusao B, should not be completely ruled out at this study stage, but be left in for future consideration as additional candidates.

Ê

1

£.

6.4 Future land use on the flood plains will be largely dependent on the protective measures to be implemented in the area. This Study provisionally categorized the area presently prone to flooding into three:

(a) The areas where the flood control project will be carried out under a short-term program by structural measures,

(b) The areas where no flood control project will be carried out for the time being, and

(c) The areas to be preserved as future flood channel.

Basic policies of management and administrative guidelines are tentatively proposed in Table 6-1 on the basis of the three categories above. The zoning of the three areas is shown in Figure 6-1.

6.5 The limited availability of basic data, such as of storm rainfall and flood hydrology, will substantially constrain the accuracy of subsequent studies for flood control. It is emphasized therefore that hydrological observations should be continued at all gages including those installed during this Study.

6.6 The characteristics of river behabior is diffeent at each river. Therefore, the long-term observation of river behavior, including the river bed change, meandering, and hydrological observation, is suggested to be done for future flood control study. Especially, it is necessary to know the behavior of natural rivers like the Panay river.

6.7 Similarly, the present studies of non-structural measures had to remain at a preliminary study level due to the limited data available.

Details of the proposed measures need to be clarified in subsequent feasibility studies, including the recommendations for legislation required for effective enforcement of the measures.

6.8 As one of non-structural measures, the preparation of flood risk map is required. Though the comparatively detailed survey for Undang flood was carried out during the additional ivestigation in June 1985, the further detailed survey is suggested to be carried out in the next stage of study for the preparation of flood risk map which would be available not only for the reduction of flood damage but also for the proper land use.

6.9 The present study assumes the sediment yield to be  $1,400 \text{ m}^3/\text{km}^2/\text{year}$  in the upper reaches in terms of denudation rate, which was derived from the observation records in the Jalaur river located in Panay island. In view of the importance of heavy siltation in the limited reservoir storage capacity, the estimated figure should be further confirmed in the subsequent studies.

6.10 In this master plan study, a simplified operation of the reservoir was proposed by providing independent storage allocation each for flood control and hydropower. In the next-phase study, more sophisticated reservoir operation can be proposed in order to make the scheme more beneficial.

6.11 A preliminary economic evaluation included in this master plan study was based on alternative thermal plant costs. The output of this study should be further refined in the forthcoming feasibility study, in which the optimization study would take into account the least cost solution of power development program of the Panay Grid.

6.12 The Present study takes into account only the retirement of old diesel plants in planning the system development. However, other than the transmission and distribution losses, deterioration in the efficiency of the existing plants should be considered. It is suggested that this matter will be clarified in the feasibility study based on more detailed

inventory survey of the existing plants.

P

P

6.13 In the present schedule for feasibility study of irrigation project, the study for Mambusao area is scheduled to start about 1 year earlier than that for Panitan-Panay area. However, it is suggested to consider to undertake the study of both areas at the same time for administrative convenience and economics of scale.

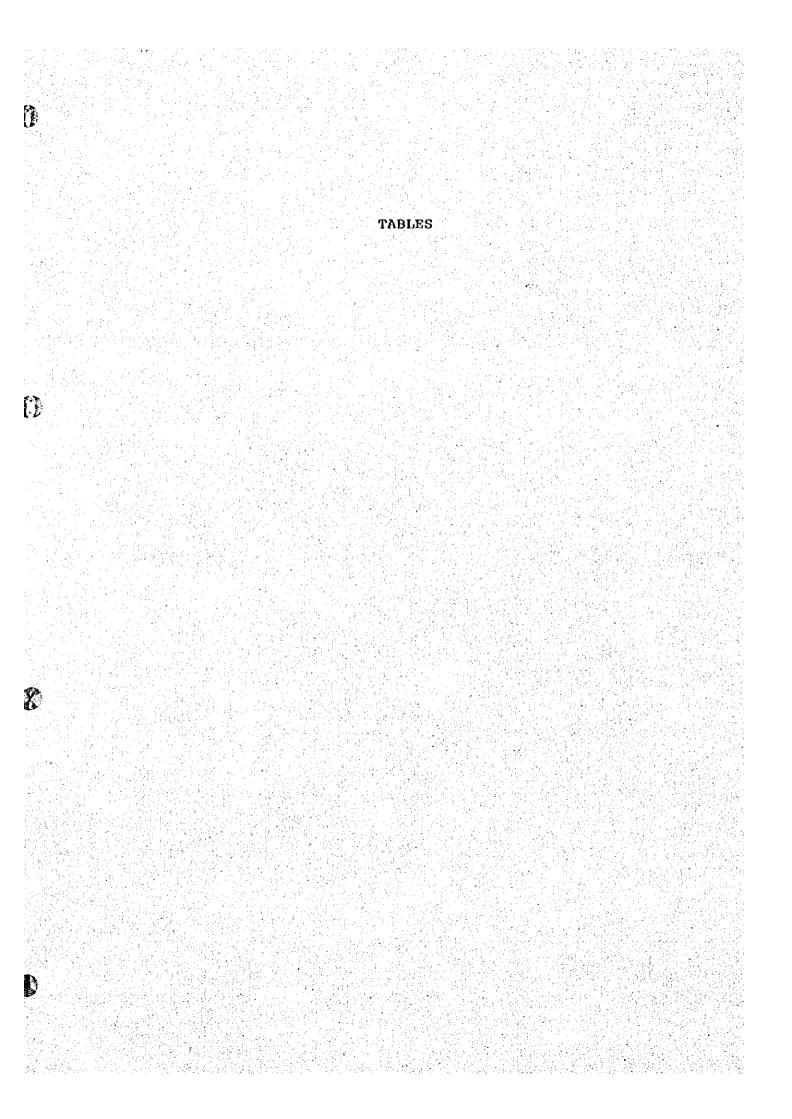

6.14 In regard to projections for future water demand, an increase of per capita consumption is expected after completion of the project. It is suggested that a sophisticated analysis on this matter is examined in the next-phase detailed study.

6.15 In the present study, the cost of water supply project is allocated only for the water supply project, nevertheless the subsidiary benefit is expected for irrigation due to the increment of fresh water. Therefore, it is suggested to consider the necessity of cost allocation for saving the cost of water supply project. However, it is noted that the benefit for irrigation cannot be included after the proposed Panitan-Panay irrigation scheme is put in service.

6.16 In the present implementation schedule of water supply project, the project is executed without phase. However, the phased execution can be also considered in case the preparation of project budget has difficulties. The phased execution is suggested to be studied in the next stage of study, if required. For example, the following phase seems to be reasonable.

- (a) Construction of tidal barrier
- (b) Excavation/dredging of the lower Panay river including the cutoff channel and construction of intake gate at the entrance to the lower Panay river.
- (c) Construction of additional pumping facilities

6.17 In paragraph 6.1 above, a comprehensive feasibility study was proposed for the 1st stage flood control project to examine all the component plans, such as river improvement, polder and dam plans, on an integral basis. Nevertheless, where separate studies are proposed due chiefly for financial reasons, priority should be given first to polder dykes, secondary to Panay B dam and thirdly to river improvement cum nonstructural measures, following economic indices (EIRR) evaluated for each component plan.

Measure	Appropriate Applications	Application to Panay River Bagin
0 8	susceptibility ement Where uses other than agricultural are competing, especially where they involve urban and industrial uses.	This measure is applicable to all areas of the basin, though agricultural land use is prominent.
Structural change	Where building/property damage is remarkable with frequent inundation, especially where the depth of flooding is not large.	This measure is applicable to the Panay river basin, in areas where floading is less than 1 m deep.
Flood proofing	Where buildings are scattered and frequently flooded, especially where flooding is less than 1 m, 3-hr advanced warning is possible.	Such measures as closure of openings and waterproofing interior would be impractical in view of type of local buildings. This plan was, therefore, not examined in this study.
Subsidised relocation	Essentially, this is a part of measures included in flood plain management. This measure is appropriate in areas where building/property damages are severe with possible risk to human life.	This measure is worthy of evaluation for all areas in the basin.
Dr.saster Dr.saster B.s. B.s. S.s. S.s. S.s. S.s. S.s. S.s.	Elsewhere.	This measure is presently undertaken. Excessive adoptio of this measure tends to remove the incentive to avoid future flood losses, and, therefore, this measure would not be an ultimate measure for the basin. No detailed evaluation was attempted in this study.
MOALLY THE LOSS DURGED Tax write-offs	Elsewhere, if approved by the government.	As in the case of disaster relief, this measure provides little incentive to reduce flood losses. Moreover, this is not supported by present legislation. Therefore no further study was attempted.
Flood insurance	Elsewhere, if insurance system is available.	This type of insurance system is presently not available and, therefore, not applicable to the basin. Moreover, this measure cannot be studied at a river basin study level, but to be left to a specific nation level study.
Flood forecasting and warning system Modify the flood	Elsewhere, and especially where flood-to-peak interval is longer than 1 day.	Applicable. This system is prerequisite as a supporting measure to any type of structural methods or other non-structural methods.
Watershed management	Where enough runoff remains in low-water period, even if this program is undertaken.	No detailed study was attempted in view of lack of data. While, forestation in the watershed area is worthy of encouragement not only for flood control purpose but als other development purposes.
