## PREFACE

The Government of Japan, in response to the request of the Government of the Republic of Indonesia, has decided to conduct a survey on the project to establish an Energy Supply-Demand Data Bank System and entrusted the Japan International Cooperation Agency (JICA) to carry out the survey.

JICA, recognizing the importance of this project for the economic and social development of Indonesia, dispatched to Indonesia a nine-man survey team headed by Mr. Takao Tomitate of The Institute of Energy Economics for the period from July 28, 1979 to March 22, 1980.

The team conducted a survey for the establishment of the Energy Supply-Demand Data Bank System.

I hope this report, compiled by the survey team, will prove to be useful for the establishment of the said bank system and for the economic and social development of Indonesia, as well as for the promotion of friendly relations between our two countries.

I wish to express my sincere thanks to the officials concerned of the government of the Republic of Indonesia for their close cooperation extended to the survey team.

March, 1980

Keisuke ARITA  
President  
Japan International Cooperation  
Agency

## 1. Outline of Technical Cooperation

The commencement of technical cooperation concerning the establishment of the energy supply-demand data bank in the Republic of Indonesia dates back to May 1977. A request for the said technical cooperation was submitted to the Japanese government by Mr. Piet Haryono, the President Director of the Indonesian State Oil and Gas Mining Enterprise (PERTAMINA).

The contents of the cooperation were confirmed between the Republic of Indonesia and Japan after submission of the request. However, there were various unclear points in connection with the Indonesian attitude and preparedness to receive the Japanese, as well as the scope of collection and filing of various data. Thus, the Japanese government dispatched a preliminary survey team to Indonesia from February 28 to March 12, 1978 in order to carry out investigations on technical cooperation concerning the project.

After their return to Japan, the team prepared the "Feasibility Study Report for Technical Cooperation on the Energy Data Bank System of the Republic of Indonesia." Meanwhile, the Indonesian side included the project in the List of Requests for Foreign Assistance (IGGI LIST) of the BAPPENAS, and at the same time submitted a formal request calling for technical cooperation to the Japanese government through the Technical Coordination Committee in the President's Office.

Upon receiving the formal request from the Indonesian government, the Japanese government examined the results obtained from the preliminary survey and studied the request. As a result, in late August 1978, the Japan International Cooperation Agency requested that the Institute of Energy Economics in Japan conduct formal investigations on the area of cooperation concerning the establishment of the energy supply-demand data bank. The Institute of Energy Economics performed its field survey from October 15 to November 13.

The objective of the field survey was to determine actual conditions in Indonesia regarding the fields which required Japanese cooperation in establishing the data bank. Thus, it was aimed at obtaining information which would help the Japanese side decide on the forms of cooperation which could be offered to the Indonesian side.

Consequently, the team was to study the situation in Indonesia by conducting the survey primarily on the following items.

- 1) Data related to petroleum and gas
- 2) Energy supply-demand forecast, and balance table
- 3) Utilization of computers at oil refineries
- 4) Overall computer utilization system

- 5) Data on energy sources other than petroleum and gas, such as electric power, coal, etc.

After these five survey items had been further broken down into 33 sub items, the survey was undertaken. The results from the extensive survey, lasting three weeks, were presented in its "Survey Report on the Energy Supply-Demand Data Bank System in the Republic of Indonesia." The basic conditions for the establishment of the Energy Supply-Demand Data Bank (EDB) system as delineated in the report may be summarized as follows.

- (1) The EDB system shall fall under the control of the MIGAS of the Indonesian Ministry of Mines and Energy, and be utilized by MIGAS and PERTAMINA with the consent of the said Ministry and the Japanese government. The data to be processed at present shall be mainly related to oil and gas, and electronic computers and software at PERTAMINA shall also be employed.

- (2) The results of the field survey show that MIGAS and PERTAMINA have sufficient data related to petroleum and gas, and in addition, the hardware, software, manpower, etc. to formulate a project to establish and EDB system and to execute it.

- (3) Important factors in establishing the EDB system include: the type of system to be considered, established, maintained, and operated; and ideas and preparations for future improvement.

According to this basic concept, the types of technical cooperation had been classified into two steps: step 1 which was aimed at establishing a comparatively simple EDB system; and step 2, a more complicated large-scale EDB system. It was noted that technical cooperation should be restricted to step 1 for the present time.

A simple EDB system designed at the first step has the following basic functions: 1) preparation of a basic energy statistical table; 2) preparation of an energy balance table; and 3) midium- and long-term energy supply-demand forecast.

Based on the basic policy described in the survey report, the Japanese government decided to offer and execute technical cooperation required for the establishment of an EDB system in Indonesia in fiscal year 1979, and entrusted the Institute of Energy Economics to undertake the actual activities.

## 2. Execution of Technical Cooperation

### 2-1 Objective and Items of Cooperation

Actual cooperative works rendered to Indonesia for the establishment of the EDB system was put into effect from the end of July 1979. The objective was to assist in the establishment of an EDB system which had been necessary for the repletion of an Energy Supply and Demand Scheme, a part of the 4th 5-Year Economic Development Plan (REPERITA IV, FY 1984-1989) set forth by the Indonesian government. Therefore, the scope of the work related to the EDB System Project was agreed upon between the two countries prior to execution of the cooperation. In the resulting Scope of Work, the objective of cooperation is stated as follows:

"The objective of the project is to enforce Japanese technical cooperation, through her experience and expertise, for the establishment of the data bank for supply and demand of energy, and its utilization system which would enable the formulation of appropriate plans on the supply and demand of energy."

After the results of the field survey of the previous year was studied and necessary adjustment of opinions made, concrete items which required cooperation were narrowed to three:

- 1) establishment of an energy data base;
- 2) preparation of energy balance tables; and
- 3) development of a medium- and long-term energy supply-demand forecast model

### 2-2 Content of Items which were Effected

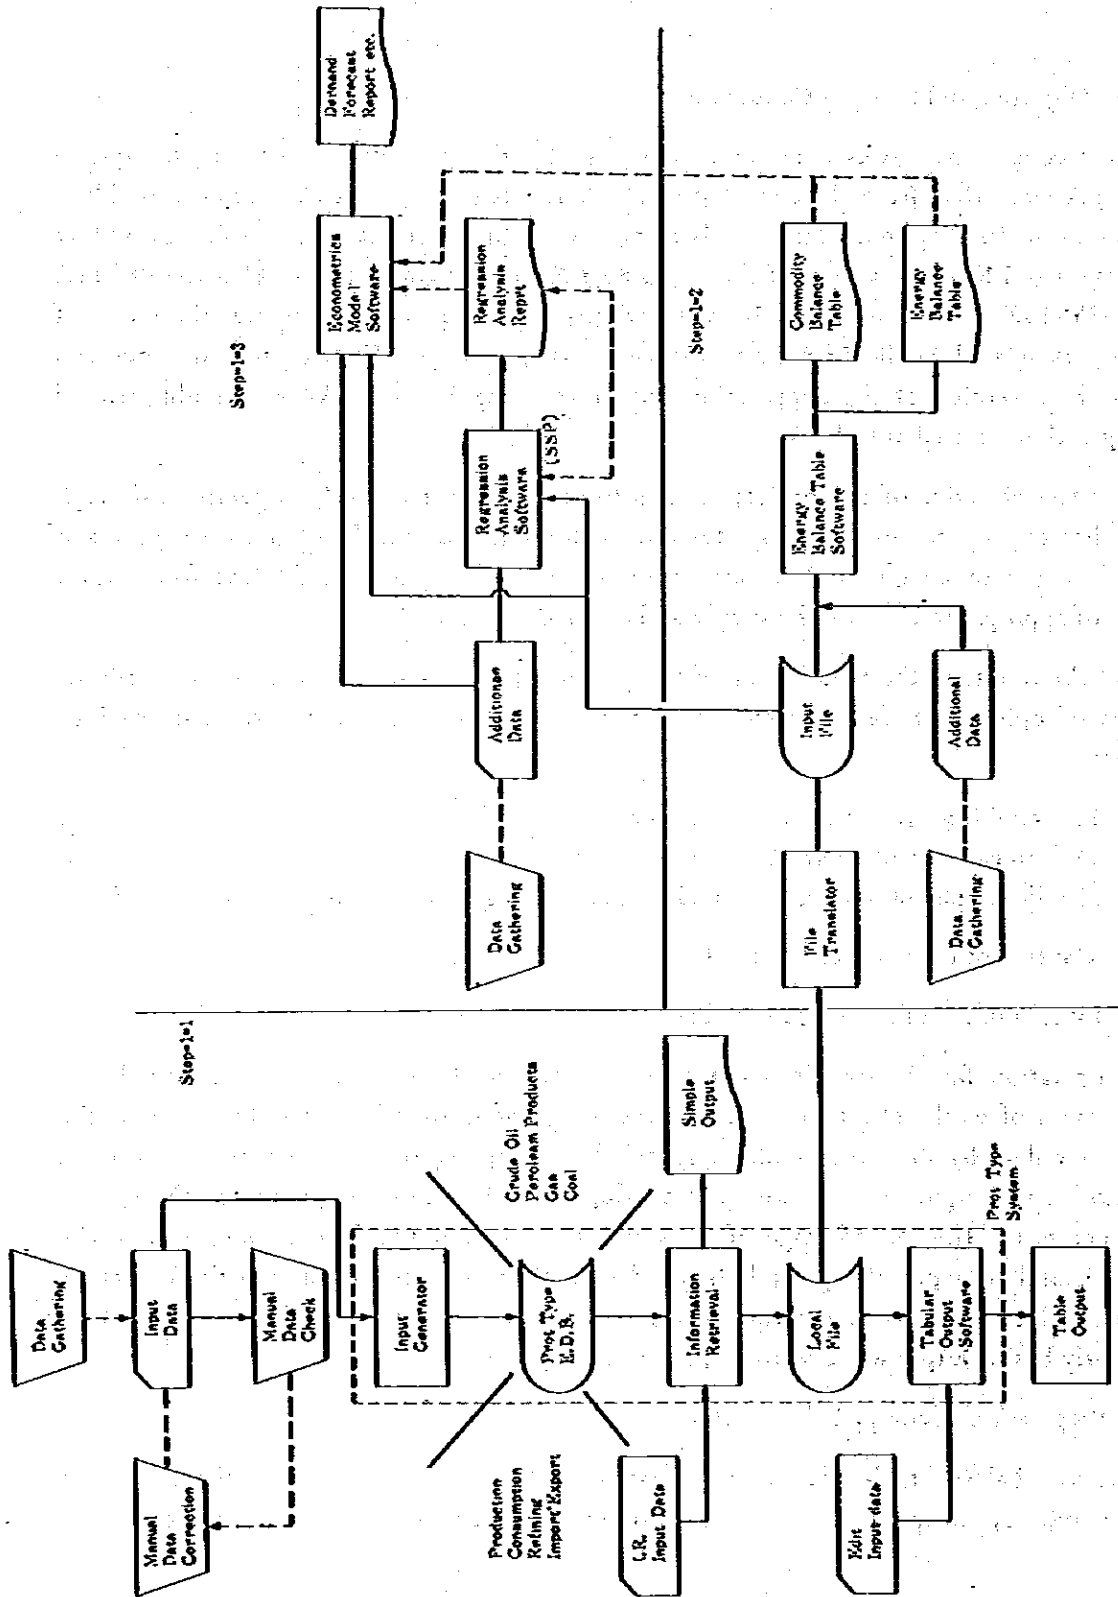

#### (1) Establishment of an energy data base

The operation for the establishment of an energy data base was roughly separated into two stages of work. The first comprised the design of an overall system which inputs the necessary data by categories under a specified form to create files, perform information retrieval and output. In addition, the development of software required for the system was necessary. The second stage of work was to determine the data to be input into the system, and to input the great bulk of data with a specified form into the computer sequentially, as well as to determine output forms for the necessary data on a monthly or yearly basis. Output was also to be performed sequentially.

#### (2) Preparation of energy balance tables

An energy balance table illustrates in matrix form, using calorific units, the process in which primary energy is transformed into secondary energy in the energy sector, and

Fig. 2-2-1 Content and Mutual Relationship of the Cooperative Operation and Division of Labor

then consumed by the industry, transportation, and residential and commercial sectors. As a result, in carrying out cooperative activities, the design of a balance table suitable for the conditions in Indonesia was a primary requirement. Next, data which are indispensable for the preparation of the designed balance table had to be collected; and the construction of an equation system for energy balances necessary for the compilation of the designed balance table was required. Finally, software capable of preparing the balance tables by inputting actual data into the equation system had to be developed. As a result, the energy balance tables for Indonesia covering the years from 1969 to 1978 were compiled in this manner.

### (3) Development of a medium- and long-term energy supply-demand forecast model

Since medium- and long-term, here, refers to a period of five to ten years, process of the works will be: first, to design medium- and long-term forecast model; second, and most important, to collect time-series macroeconomic data from the past decade, and collect data related to energy which would not be input to the data bank – indispensable elements for establishing the structural equations of the forecast model, and in deciding the values of exogenous variables; and third, to develop the medium- and long-term model and associated software. With regard to the cooperative operation in this fiscal year, various restrictions were imposed on the development of the model, primarily due to the lack of necessary time-series data. However, sufficient forecast results up to 1990 could be obtained.

The cooperative items were effected in accordance with the above described contents and procedures in Indonesia and Japan respectively, taking the form of a cooperative operation.

Figure 2-2-1 illustrates the content and mutual relationship of the cooperative operation and division of labor.

## 2-3 Composition of Members Involved in the Cooperative Operation

### (1) Composition of the JICA Expert Team

The JICA Expert Team consists of nine members including energy economists, system engineers, and system analysts. A total of eleven members participated in the field survey taken three times. These experts plus one additional took part in the cooperative operation in Japan with the Indonesian members.

### (2) Composition of Indonesian Counterpart

In undertaking the project, the Indonesian side formed a team consisting of experts in the related fields at MIGAS, LEMIGAS, and PERTAMINA in order to participate in the cooperative operation. The number of members in the team reached nearly 30, while the number of members who were dispatched to Japan as trainees exceeded 20, 4 of whom were received by the JICA.

Table 2-3-1 Members of the JICA Expert Team

Name	Distribution of Work
Takao Tomitate	Coordinator
Hitoshi Shozawa	Energy balance table
Kenichi Matsui	Energy supply-demand forecast model
Yoshio Hara	Assistant coordinator, energy statistics
Yoshiki Ogawa	Energy balance table, software for the balance table
Akio Sonobe	Data base, field coordinator
Koichi Osada	Software for the data bank
Shoji Yoshikoshi	Software for the data bank, software for the forecast model
Seisuo Takemoto	JICA
Toru Nishizutsumi (Domestic operation)	Energy supply-demand forecast model

Bunyani	PERTAMINA	Software for the data bank

## 2-4 Operational Schedule and its Content

### (1) Operational schedule and its content in Indonesia

The Japanese expert team was dispatched to Indonesia three times, and one professional was stationed in Indonesia throughout the operation of the project.

The first expert team was dispatched from July 28 to September 8, 1979. Immediately after determining the scope of the project for this fiscal year, they moved onto the execution of the operation. The first cooperative works included: 1) deciding on the types of data to be input, and the input form; 2) deciding on the forms of data output which could be obtained as statistical tables, and formulating a rough outline of the form; 3) determining the number of rows and columns in the balance tables, and confirming the availability of data; and 4) establishing software for data input into the data bank, etc.

The second team was sent on December 4 and stayed in Indonesia until December 30, 1979. Their work included: 1) preparation of software related to the energy balance table; and 2) installation of software for data retrieval and output.

The third team was dispatched from March 5 to March 11, 1980, taking over the half-completed operation. During their short stay, the work covered: 1) clarification of the problems which had arisen during the course of the cooperative operation up to that stage; and 2) discussions on the direction which the expansion of the data bank should be led in the future, and methods of cooperation required for the expansion.

### (2) Operational schedule in Japan and its content

The first domestic operation was undertaken from September 17 to November 20, 1979, succeeding the work carried out by the first dispatched team. The operation took the form of a joint operation between the Japanese and Indonesian members. The number of countermembers who had visited Japan during this period totalled 14, including 2 trainees received by the JICA.

The work of the first domestic operation consisted of: 1) construction of the equation system for energy balances; 2) input of actual data and experimental compilation of the 1978 balance table; and 3) preparation of software for data retrieval from the data bank and data output.

The major objective of the second domestic operation, undertaken from December 13, 1979 to February 17, 1980, was to develop a medium- and long-term energy supply-demand forecast model. As a result, the first half of the operational period was concentrated on the conceptual design of the forecast model. Based on the conceptual design, equation of the model and exogenous variables were set up. In the latter half, real data were input to obtain results, and software required for the operation of the model was also developed.

In order to determine the real situation of energy supply and demand in the Japanese

major industries, four field trips were made during the course of the first and second domestic operations.

**Table 2-4-1 Field Trips to Major Domestic Industries**

Date	Name of Factory
First trip Oct. 4-5, 1979	Kashima Plant of Mitsubishi Petrochemical Co., Ltd. Kashima Oil Refinery Kashima Ironworks of Sumitomo Metal Industries, Ltd.
Second trip Oct. 18-19, 1979	Hamaoka nuclear power plant of Chubu Electric Power Co. Ltd. Toyota factory of Toyota Motor Co., Ltd.
Third trip Nov. 7, 1979	Isogo steam power plant of Electric Power Development Co. (Coal) Minami-Yokohama steam power plant of Tokyo Electric Power Co., Inc. (LNG) Negishi factory of Tokyo Gas Co., Ltd.
Fourth trip Feb. 4, 1980	Nagoya Ironworks of Nippon Steel Corporation LNG receiving station of Chubu Electric Power Co., Ltd.

### 3. Energy Supply-Demand Data Bank

#### 3-1 Outline of the Data Bank System and Its Usage

The data bank system (hereinafter referred to as EDDBS) provides for the creation and updating of energy-related information files, as well as extraction, editing, and printout of necessary information.

Since the EDDBS handles diversified and massive data related to energy, it requires an efficient data access method. Therefore, the EDDBS employs the concept of "list structure" which manages data in terms of energy types, or data categories such as production volume and consumption volume.

Fig. 3-1-1 Data Categories

Original data which is processed in an EDDBS-type system is input in an encoded form. Since data is prepared based on a table which the actual names and codes, errors may possible occur in copying or punching. Thus, the EDDBS provides a "Data Check System" (hereinafter referred to as DCS), a sub-system to prevent transmission of mistakes into the information file.

The DCS determines whether there is a code which is not registered in the corresponding table with the actual names, and whether the sum of values of the header data (Refer to 3-1-1) matches the sum of values of the original data (balance check).

#### 3-1-1 Creation and Update of the Information File

The EDDBS provides three functions for creation and update of the information file.

- o Addition of new data

- o Correction of existing data
- o Deletion of existing data

Two types of data are required in order to utilize these functions. The first is the so-called directive data, specifying which of the functions will be used, and the second is a set for updating the information file depending on the selected function.

Directive data

There are three types of directive data indicating addition, correction, or deletion, and each type is paired with an end of data directive indicating the conclusion of the updating data set.

ADD	Addition of new data
CNG	Correction of existing data
DEL	Deletion of existing data
EOD	End of data

Thus, the data configuration may be one of ADD to EOD, CNG to EOD, or DEL to EOD.

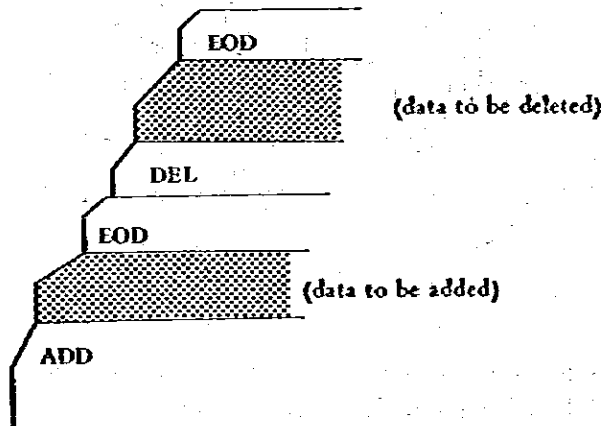

Fig. 3-1-2 An Example of Data Configuration

Data updating the information file

Since the format for updating data differs according to the function, preparation of updating data for each case will be discussed below.

Addition of new data (ADD)

Data for addition is divided into several groups, each consisting of a group header, data to be added to the information file, and a group end (END).

The group header defines the period for which data following the header will remain in the file, along with other information. The value in the header is maintained until the group end is encountered (Refer to Page 15).

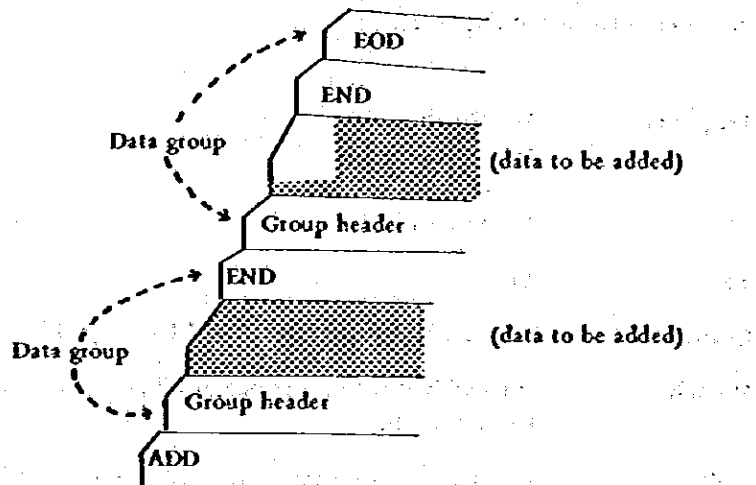

- Frequency            M: Month  
                          Q: Quarter  
                          Y: Calendar year  
                          F: Fiscal year
- Year                    Year
- Quarterly            If quarterly data, indicate one of 1 through 4.
- Monthly              If monthly data, indicate one of January(1) through December(12).
- Scale                 A scaling factor for the value of additional data (the column of Amount) is indicated in terms of an exponent of 10.  
                          If Scale = 2 and the value of data is 100.0, the data will be processed as  $100.0 \times 10^2 = 10000$ .
- Unit                  A unit of the value of updating data (the column of Amount); the following table shows available seven units.

No.	Code	
1	BBL	Barrel
2	KL	Kirolitres
3	M3	Cubic metre (m <sup>3</sup> )
4	MCF	
5	MT	10 <sup>3</sup> tons
6	BTU	British thermal units
7	KWH	Kirowatt hours

Table 3-1-1 Available Units

- Sub-Total            Used for balance check of data

Data to be added to the information file, (Refer to Page 16), as mentioned earlier, are in encoded form. Although the example shown below is a configuration for oil-related data, the one for gas-related data is the same.

**Fig. 3-1-3 An Example of an Additional Data Configuration**

Correction of existing data (CNG)

The EDBS handles correction of existing data as replacement of data. The data to be corrected is deleted from the file by giving its record number, and then the correct data is inserted in its place. The data configuration for CNG is similar to that of ADD.

The group header indicates the record number of data to be replaced (the column of Element No. on Page 19). The updating data follows the header (the same as shown on Page 15). Since the header and updating data are in pair, the group end required for ADD ) is not necessary for CNG.

Deletion of existing data (DEL)

Existing data is deleted from the file by giving the record number of the file to be deleted (Refer to Page 20).

### 3-1-2 Extraction of Data from the Information File

A partial set of data is created by extracting data from the information file using a key code and/or sub-code. Then, the partial set is converted to a set of necessary information through logical operation of the key code.

Directive data and extraction indicating data require the utilization of this function of extraction, similar to the case of updating.

#### Directive data

RET        directive data for extraction  
EOD        End of data

#### Extraction indicating data (Refer to Page 22)

As mentioned earlier, this consists of a key code and sub-codes. However, there may be two cases: the first only uses a key code, and the other uses both a key code and a sub-code.

For example, if the entire information concerning crude oil is necessary, only an appropriate key code (=1) is used, whereas if information concerning specific crude oil is necessary, then a sub-code must also be used.

Table 3-1-2 Table of Key Codes

Key Code	Classification
1	crude oil
2	petroleum products
3	gas
4	coal
5	other energy sources
6	consumer sector
7	oil refinery and gas plant
8	PERTAMINA Marketing region
9	SEAFED DEPOT
10	countries of transaction
11	domestic transportation
12	data category
13	sub-index 1
14	sub-index 2
15	year
16	month or quarter
17	data period

(Note) Sub-codes include names of individual crude oils and manufactured goods.

Fig. 3-1-4 The Case where More than Eight Sub-Codes are Used for One Key Code

There are two special types of key codes, "99" and "SV", which are used in the following cases.

"99" is used to write a logical expression of the key code to create a necessary set from a partial set (Refer to Fig. 3-1-4). When the sum of values of extracted data is desired, unit conversion of the individual values is performed by indicating a unit, such as BBL, in columns 6 through 8 of the "99" card so that the sum of the values will be printed out with a uniform unit. The built-in unit conversion table of the EDBS is shown on Page 24. If columns 6 through 8 are blank, no sum is printed. Furthermore, if a variable name included in the energy balance table is indicated in columns 73 through 80 of the "99" card, the sum, in addition to the variable name, will be transferred to an intermediate file. On the other hand, "SV" is used to transfer a set of extracted data to an intermediate file for editing purposes. A label, required to manage the extracted set for its transmission to the intermediate file, is indicated in columns 6 through 8 of the SV card.

### 3-1-3 Edition of Extracted Data

The EDBS edits extracted data, then prints out any number of tables from among the 95 shown on pages 28 and 29 specified by REPORT NO. and SUB NO. Data requiring use of this function consists of directive data and edition indicating data.

Edition indicating data (Refer to page 27)

By writing in the label name (on the specified "SV" card) of the extracted information given for its transmission to an intermediate file at the input file columns, appropriate information is read from the intermediate file.

If a specified report edits information more than two years old (FORMAT on pages 28 and 29 is F1 or F2), the oldest year must be specified at ADDITIONAL INFORMATION.

Data input into the EDBS is currently monthly-based data. However, it will be more efficient to have yearly-based data for possible interface with the energy balance table in the future.

Therefore, the EDBS is equipped with a function called YEARLY DATA OPTION which not only edits a specific report, but also writes out yearly data on a disk with the format described on page 15 and page 16. If "G" is entered in YEARLY DATA OPTION, yearly-based data is created in the format shown on pages 34 through 37. Since this function has not yet been fully established, a detailed description is not given here.

.
END
    
```

2) Report no.15-2 (Fiscal Year)

Data frequency : F instead of Y

3-1-4 Printing of Information Files (Refer to page 39)

Any contents of the information file can be printed out. By specifying the record number of the information file, partial printing is also possible.

In addition, the EDBS provides a function to print major tables and LINK ADDRESSES of the ELEMENT FILE in order to check the system's list structure.

3-1-5 Structure of the Data Deck

The first card of the data deck must be either "INIT" or "REST". If INIT is placed at the beginning, an initial state where all of the tables, files, and counters have been cleared is established. If REST is used, a restart is initiated based on previously stored information (Refer to Fig. 3-1-5).

## 3-2 Future Improvement of Energy Supply-Demand Data Bank

### 3-2-1 Preparation of Input Data

(1) After proceeded with the steps of task, that is implementation of input data, more than about 200,000 items have already been prepared. But it may not be said that implementation of the data is completely finished in the sense of checking the data and so forth.

Hereafter, obtaining many kinds of output tabulations and verifying the errors caused by the mol-definition and the lack of data, it would be necessary to make every effort for the data base to be most precise and reliable finally.

(2) At the present time, the kinds of data prepared are limited to the following ones, that is to say; the crude oil and the related products, the natural gas and the related products and the coal.

The data about the all kinds of commodities that would appear in the column of the Energy Balance Table except the data finally made sure that can not be collected should be prepared, so it is necessary to collect the data as soon as possible with the help of sections or organizations related and to make sure that the data base be complete.

(3) At present, the data is prepared for the period from January 1974 to June 1979 and the data after July 1979 must be prepared and implemented continuously.

As the initialization phase, all the data for the period mentioned above was arranged at a time, but hereafter the data should be arranged and generated to the data base monthly in the routinized base.

All the data can not be necessarily obtained from Migas and Pertamina, it would be necessary to establish the procedure so as to be able to get the data related continuously and in the routinized base with the help of organizations related.

### 3-2-2 Energy Supply-Demand Data Bank System

The EDDBS employs the concept of "list structure" to extensively process diversified and massive data related to energy in order to attain high utilization efficiency. However, the volume of input data turned out to be more than three times greater than both the Indonesian and Japanese sides had expected, totaling 200,000 cases. Thus, provisional modification of the system was performed to enable the acceptance the 200,000 cases of data. It is clear that the relationship between computer processing time and volume of data is described by an exponential increase rather than a linear one. As a result, it is difficult to attain efficient operation of the present system when handling such a volume of massive data. Moreover, the system requires an enormous capacity of disks to maintain the massive data.

Although drastic modification of the present system's basic concept is not required for efficient operation of the EDDBS, the file structure, method of maintaining the original data, and other aspects must be reviewed. This may result in the necessity of implementing measures, such as the introduction of auxiliary files.

The project for this fiscal year concentrated on the technical cut-over of the basic concept of the system, and did not attend to through studies on the operation of the system. However, it seems necessary, for the efficient operation of the EDDBS, to establish a back up system for the maintenance of the information file which was constructed from the original data. In other words, should problems stemming from the computer itself, or those from the EDDBS, be generated during the updating of a file, some measures must be taken to assure a smooth restarting.

#### Data period

Regarding the data period, all data were input to the system on a monthly basis throughout this fiscal year. It is more efficient in the cases where data are dealt with to some extent on a macro basis — such as for the forecast of energy supply and demand, and energy balance table — to input data on a half-yearly or yearly basis. As mentioned earlier, a function which automatically creates yearly-based data for some types of data was included in the EDDBS experimentally, but the function has not been fully established as of yet. The mechanism as constructed experimentally is basically sufficient for the function, and therefore expansion of the mechanism to cover the overall data is required.

In view of effective utilization of the data bank to meet the objectives, it may be advisable to divide the data bank into multiple data banks depending on function and usage — such as a micro data base and a macro data base — rather than to unreasonably attempt to formulate a single data bank. If linkage to the energy balance tables and the energy supply-demand forecast model prepared in this fiscal year is taken into account, the data bank can be improved by transmitting information using a macro-based data bank, furthermore inputting data regarding population and economy in general together with energy-related data into the macro data base. This would also lead to expansion of the scope of utilization, and improvement of the forecast model.

#### Timeliness of data

The EDDBS provides functions for retrieval of necessary information from the information file, edition, and printout. These functions are required for immediate response.

The present system was designed to operate on a batch basis. By considering a possible shift to an interactive system, timeliness of the information could be strengthened so as to markedly improve the effective utilization of information.

## 4. Energy Balance Table

### 4-1. Concept of Energy Balance Table

Now that no one can deny a fact that quantities of energy resources are limited, how efficiently use the limited energy is becoming a common subject to all the nations in the world.

To outline and analyze energy economics of a nation, it is essentially required to grasp following factors; domestic production of energy, import and export of energy, transformation process of energy, supply process of energy to final consumption sector and correlation among different types of energy resources.

To indicate a flow of energy in the form of a statistical tabular statement, it is considered optimum to introduce a matrix mode in which various types of energy resources are put lengthwise as columns and individual fields of economic activities crosswise as rows. Fig. 4-1-1 shown below represents a matrix prepared as aforementioned.

To prepare an energy balance table, supply conditions of energy deduced from domestic energy production, energy import and export and stock change are to be drawn up first. To be indicated secondly is transformation from primary energy into processed energy (secondary energy) and energy requirements in energy industries engaged in such a transformation. The last step is to indicate types and quantities of energy used in final consumption sector.

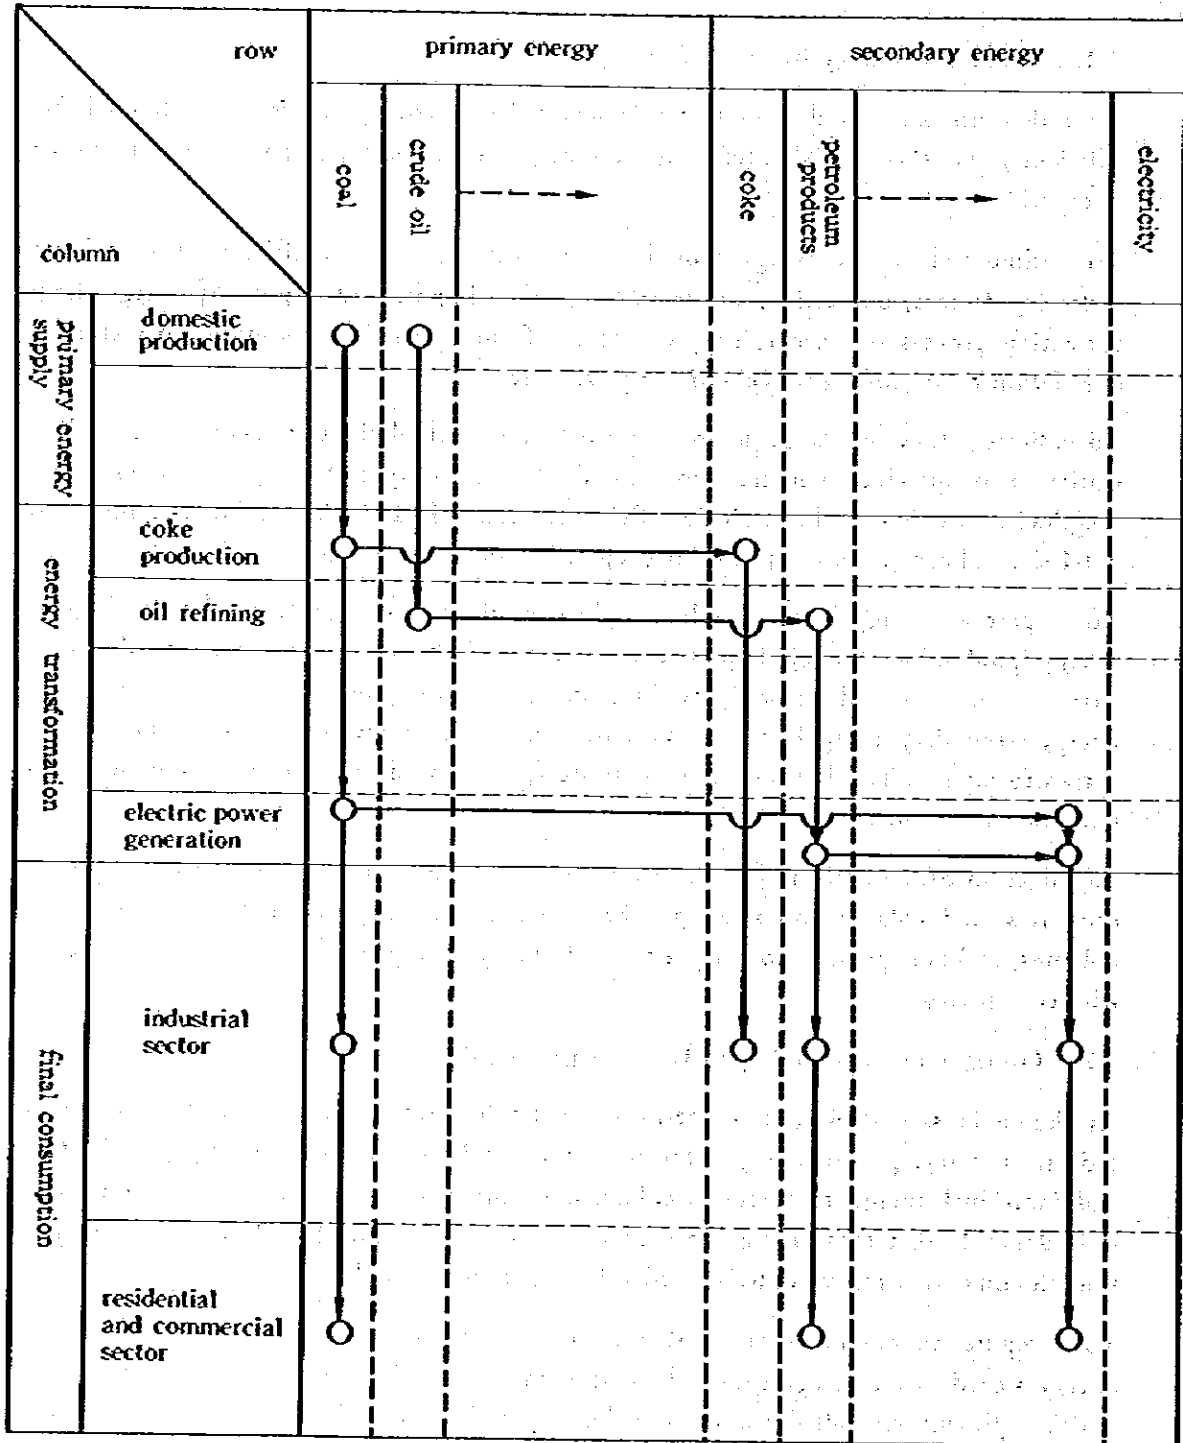

Introduction of a matrix mode, in other words, stating quantitative output and input for each row and column and striking a balance between supply and demand concerning columns, makes it possible to grasp a flow of energy as a whole from a quantitative aspect with consistency.

### 4-2. Configuration and Coding of Energy Balance Table

As shown in section 4-1, in a energy balance table, supply sources of primary energy, industries carrying out energy transformation and end consumers are put in rows and individual energy resources in columns. To make an analysis and map out policies, it is desirable that these items are subdivided as much as possible although accuracy of statistics on energy resources to be used as basic data is essential.

To compute an energy balance table with a computer by recalling basic statistics on energy stored in an energy supply-demand data bank, it is indispensable to decide codes which represent individual rows and columns of the energy balance table and establish display formats of energy basic statistics and energy balance expression. Given in Table 4-2-1 and 4-2-2 is configuration and codes of rows and columns of an energy balance table

Fig. 4-1-1 Schematization of Concept of Energy Balance Table

prepared for Indonesia. A notable feature of the energy balance table prepared for Indonesia is that fuel consumption attendant upon petroleum products and raw material consumption by the chemical industry are clearly marked off. Although naphtha is included in fuel oil total when an energy balance table is to be prepared for Japan, it is not in preparing one for Indonesia. Further, chemical industry's raw material consumption is specifically established as the 59th row in the Indonesian energy balance table.

Table 4-2-1 Configuration and Codes of Rows of Energy Balance Table

| Row No.   | Coding Symbol | Title   |
|---|---------------|---|
| <b>(1) Primary Energy Supply Sector</b>   |               |   |

### 4-3. Basic Statistics on Energy

It is basic statistics on individual energy resources that form the basis of an energy balance table.

When establishment of an energy supply-demand data bank, a part of this project, is completed and all the basic data are compiled in a computer file, it becomes possible to recall basic statistics by type of energy and by period, such as monthly basis, quarterly basis, annual basis and fiscal year basis. For calculating data shown in the energy balance table prepared this time, however, it was not possible to use the data bank because establishment of the bank was carried out in parallel with preparation of the energy balance table and all the basic statistics were not input in the bank. Accordingly, basic statistics by type of energy were obtained from various materials prepared by the Ministry of Mining and Energy for the 1969-1978 period on annual basis. Some data which were not available were calculated on a reasonable supposition which could make supply and demand well balanced.

In the collected statistics, units peculiar to individual energy resources are used, which means a principal table which forms the base of the energy balance table contains a variety of units. Accordingly, it is not possible during this stage to carry out addition and subtraction of values among different types of energy resources expressed with different units nor to calculate total energy demand of a nation. One of the purposes of an energy balance table is to establish a unit common to all the types of energy resources which enables us to carry out addition and subtraction of values among different types of energy resources, calculate total energy demand and indicate quantitative variation among alternative energy in the table to some extent.

There are various kinds of units, such as price, thermal quantity, horsepower and Kwh, which can be adopted as a common unit. Because the subject is energy, it is desirable to adopt a unit of thermal quantity, such as calorie and joule. Apart from such a viewpoint, it has been usual to adopt a unit of thermal quantity as a unified unit because it is most popular to use energy as sources of heat. For example, expressions such as "tons in terms of coal equivalent" and "tons in terms of oil equivalent" should be more clearly defined based on thermal quantity.

Now, combustion heat is usually adopted as a thermal quantity scale factor to convert values of different energy resources presented with different units into values to be presented in the form of thermal quantity, the unified unit. It should be noted, however, combustion heat value depending on production place and property of products even among a type of energy. Accordingly, to obtain an exact value, it is required to obtain combustion heat and quantity of products by place of production and property, which are summed up to gain total quantity of a type of energy. Such an operation requires a considerable labor and time and is virtually impractical.

The secondary desirable measure is to prepare average value of combustion heat by type of energy resource based on a certain method which can be accepted as a standard. To practise such a measure, it is required to establish a standard method to measure combustion heat, continue to take samples of products of various origins and properties and measure combustion heat of the samples to collect data of numerical value which enable us to obtain average value of combustion heat of individual energy resources.

In this light, data which enable us to obtain average value of combustion heat are not available in Indonesia at present. Moreover, it seems that a system which permits us to conduct experiments to obtain average value of combustion heat is not yet established, either. To prepare the energy balance table this time, a thermal quantity scale factor used in "Energy Data on Developing Countries Vol II" prepared by OECD was referred to except a few cases.

While tons coal equivalent is used as a unified unit of thermal quantity, 1 TCE (tons coal equivalent) is defined as  $7 \times 10^6$  Kcal. This is because of a strong request made by Indonesia, who considers to give a priority to coal in future energy policies of the nation.

#### 4.4. Construction of Equation System of Energy Balances

It is necessary to construct equations of calculation required for preparing an energy balance table. Listed below are all the equations constructed.

It will be worthy to explain codes of items of basic statistics by type of energy. A code of an item consists of a character code representing a category and combination of three-character codes, one representing an energy activity sector and the other type of energy (See Table 4-2-1 and 4-2-2). In other words, general form to express an item code is as follows;

|                         |                             |   |  |
|-------------------------|-----------------------------|---|--|
| A-character code        | Three-character code        | & | Three-character code                     |
| representing a category | representing type of energy |   | representing an economic activity sector |

(ex. POGR; domestic production of crude oil, CAGS & AIR; consumption of aviation gasoline for air transportation).

Codes explained above are used for indicating items of individual statistics in equations.

To set codes of thermal quantity scale factors for individual energy resources, a letter code "F" representing thermal quantity factor is combined with three-letter codes representing individual energy resources (ex. FSCO; general-purposes coal thermal quantity scale factor, FOGR; crude oil thermal quantity scale factor).

LOCATION SYSTEM OF ENERGY BALANCES

(1) Coking Coal

1. Import  
EKC02052 + EKC02000
2. Stock Change  
EKC02025 + EKC00(-1)-EKC01000
3. Total of Primary Energy Supply  
EKC02026 + EKC02022-EKC02025
4. Transformation to Town Gas  
EKC02014 + -EKC04000/EKC0
5. Transformation to Coke  
EKC02015 + -EKC04000/EKC0
6. Total of Energy Transformation Sector  
EKC02017 + EKC02016-EKC02015
7. Export  
EKC02028 + -EKC00000
8. Total of Energy Industry On Use Sector  
EKC02029 + EKC02020
9. Statistical Difference  
EKC02030 + -EKC02024-EKC02017-EKC02029

(2) Steam Coal

10. Domestic Production  
EKC03031 + EKC00000
11. Export  
EKC03033 + -EKC00000
12. Stock Change  
EKC03025 + EKC00(-1)-EKC01000

#### 4.5. Software for Preparation of Energy Balance Table

As mentioned in sections 4.3 and 4.4, we collected basic statistics on energy and built up equations of calculation required for preparing an energy balance table. Needless to say, it is possible to prepare an energy balance table by making manual calculation based on basic statistics on energy and equations of calculation. However, it is desirable to develop computer software so as to realize faster data processing. As indicated in the preceding chapter (Chapter 3), an energy supply-demand data bank system was developed in this project which was capable of storing micro data, aggregating them into basic statistics on energy and generating such statistics as an output. Accordingly, if the energy supply-demand data bank system could be linked with preparation of an energy balance table, it would become possible for us to grasp the flow of energy much faster.

For developing software for preparation of an energy balance table, we set up the following three points as basic policies.

The first point is to link the energy supply-demand data bank system of which development has already completed as mentioned before with our preparation of the energy balance table by some means, in other words, to receive basic statistics on energy from the data bank which can aggregate micro data and output the results and make the best use of them in our preparing the energy balance table. However, data scheduled to be stored in the energy supply-demand data bank system this year are primarily those on oil and gas and data on electric power, coal and other types of energy are not scheduled to. Accordingly, it is required to acquire a function to read out data on the latter types of energy from descriptions contained in cards. As a method to link the energy supply-demand data bank with our preparation of the tabular statement, following is considered; to set an intermediate file and, using an energy supply-demand data bank system, to output basic statistics on energy into the intermediate file first. The basic statistics on energy are then input into a program of energy balance table.

The second point is related to configuration of the energy balance table, that is, to write numbers and titles of rows and columns directly in the program without giving them as data. When configuration should be changed, we can complete such operations only when we change FORTRAN statements and numbers of data contained in the program. Changes in configuration of the table are required only when a number of items of energy should be newly added or a comprehensive change in structure of industries is needed. It is considered that processes to change the program in accordance with such new requirements are not so troublesome.

The third point is to give codes to equations of energy balance without writing them directly in the program. Because Indonesia is still on the way in establishing a system of basic statistics on energy and it is quite probable that methods to collect statistics will be changed substantially, which means that equations of calculation of the energy

balance table should also be changed frequently. Such being the situation, it will be extremely troublesome to change the program every time such a need arises and to compile a program newly. To avoid such a trouble, it is necessary to attach a function to the program to read equations of calculation as data and make calculations by decoding them.

While we were engaged in preparation of software in accordance with the aforementioned three points established as basic policies, the third point, in particular, is considered to form a special feature of software.

Fig. 4-5-1 shows configuration of the program in which correlation between a main program and subroutines is indicated.

Fig. 4-5-1 Configuration of Program

To read equations of energy balance as data, recall basic statistics on energy stored in the energy supply-demand data bank, make calculations in accordance with equations of energy balance and output an energy balance table, the following four steps are required.

1. To read out equations of energy balance from a permanent file, extract variables other than those indicated in each column of the energy balance table, that is, variables representing basic statistics on energy and variable names of intermediate variables from the equations, and prepare a position where values of these variables are to be stored (subroutine CLSVAR).

2. To read variable values extracted in a manner mentioned above from a file prepared using an energy supply-demand data bank reference system or paper cards, and prepare variable values required for calculations (subroutine DATSET).
