A. I - 2. Microscopic observation of the thin sections

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
686	A301	8	PU	Micrite	Silt sized detrital quartz (less than 10 per cent) and about 15 per cent of fossil fragments, which are replaced perfectly by coarsely crystalline calcite, are cemented by finely recrystallized anhedral mosaic of calcite.
692	A318	10	CG	Granite	Rock shows granular texture and composed mainly of quartz (subhedral or anhedral, weakly sheared but can not be observed wave extinction), alkali feldspar (subhedral or anhedral, mostly perthite), plagioclase (anhedral or subhedral, oligoclase, zonning clear, altered to fine mixture of sericite and clay mineral), biotite (anhedral, bending cleavage, weak pleochroism, many part altered to chlorite) and a small quantity of iron ore.
700	A333	20	TR	Quartz porphyry	Rock shows porphyritic texture and composed mainly of quartz (anhedral rounded, 3.60 x 1.62 - 0.25 x 0.03 mm, many cracks), alkali feldspar (anhedral rounded, orthoclase and perthite, 1.85 x 1.00 - 0.88 x 0.72 mm, pale gray color, inclusion of square black magnetite, and embayed sericite), plagioclase (euhedral, 0.64 x 0.45 - 0.25 x 0.10 mm, An25-20, dirty crystal, weak twinning plane, marginal altered to sericite) and biotite (1.41 x 0.34 - 0.76 x 0.12 mm, altered to fine mixture of iron ore and sericite). Black square magnetite occurs as accessory mineral. Groundmass is net texture and consists of aggregation of fine sericite and undetermined clay minerals. Only one fan figure muscovite occurs with biotite.
701	A335	20	PU	Andesitic tuff	Rock shows granular texture with weak schistosity. Constituent minerals are quartz (irregular anhedral, less than 0.08 x 0.06 mm), and calcite (irregular grain, less than 0.18 x 0.10 mm). Matrix is filled by pale brown clay undetermined mineral and pale gray volcanic ash. Fragments of andesitic rock (less than 0.95 x 0.80 mm, probably pyroxen andesite) occurs.
705	A414	23	PU	Oosparite	Original rock is oosparite, which consists of more than 70 percent of oolite and rather coarse sparry calcite matrix. Original textures are still remained, but particles have been replaced perfectly by fine anhedral mosaic of dolomite.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
728	C411	4	MP	Quartz porphyry	Consists mainly of very fine grains of quartz (irregular anhedral over 90 per cent) and feldspar (a few per cent). Rock is intruded by quartz and aplitic veins.
738	I301	6	PU	Biomicrite	More than 80 per cent of fragmental sponge secules are cemented by microcrystalline calcite. Small pellet like aggregations of clayey matter are observed sporadically. Rock is weakly recrystallized.
744	I312	7	CG	Granite Porphyry	Rock shows porphyritic texture and composed of quartz (1.44 x 0.92 - 0.12 x 0.09 mm, anhedral), alkali feldspar (subhedral, almost perthite, 3.26 x 2.06 - 0.40 x 0.15 mm), plagioclase (euhedral - subhedral, 1.96 x 0.30 - 0.25 x 0.06 mm) and anhedral magnetite. Groundmass shows fine fluidal texture and consists of mixture of plagioclase and pale gray glass.
746	I326	11	PU	Micrite	Composed mainly of very fine microcrystalline calcite with irregular shaped cavities, which are filled by sparry calcite.
747	I327	11	PU	Biosparite	More than 70 per cent of fragments of calcareous algae, echinoid spine and molluscan shell are cemented by coarsely crystalline sparry calcite. Rock is more or less recrystallized.
754	L304	21	PU	Rhyolitic tuff	Many angular fragments of quartz are scattered in volcanic ash. Plagioclase (euhedral, less than 0.90 x 0.56 mm, weakly altered to sericite), biotite (euhedral or anhedral, less than 0.36 x 0.03 mm, weak pleochroism), anhedral magnetite and alkali feldspar (anhedral, perfectly altered to fine clay mineral) occur as accessory minerals.
755	L305	21	PU	Micrite	Rock is composed mainly of very fine microcrystalline calcite with a few per cent of subangular very fine grained quartz. Rock is crushed tectonically and cemented by coarsely crystalline calcite.
766	L324	21	PU	Micrite	Less than 30 per cent of shell fragments of bivalves, gastropods and ostracods, about 10 per cent of very fine to silt sized subangular quartz, and spherical aggregates of clayey matter are cemented by very fine microcrystalline calcite. Shell materials are replaced perfectly by coarsely crystalline calcite.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
768	L329	21	PU	Micrite	More than 50 per cent of shell fragments of echinoids and 10 to 20 per cent of very fine grained angular detrital quartz are cemented by microcrystalline calcite. Fossil remains are perfectly replaced by coarse calcite crystals.
772	L347	6	PU	Dolomite	Composed mainly of finely crystalline (less than 0.1 mm) anhedral mosaic of dolomite, and 15 per cent or more of very finely crystalline quartz which is originatted from hydrothermal solution.
773	L353	6	PU	Dolomite	Composed mostly of medium crystalline (less than 0.2 mm) anhedral mosaic of dolomite with a few per cent of very fine grained detrital quartz.
774	L358	6	PU	Pelmicrite	Less than 10 per cent of shell fragments, about 20 per cent of fine grained detrital quartz and pellets are cemented by muddy microcrystalline calcite. Micritic matrix, shell fragments and pellets are incompletely recrystallized to fine to coarse anhedral mosaic of calcite. Sporadical aggregations of fine crystalline quartz, originated from hydrothermal solution, are observed.
777	L377	22	PU	Dolomite	Composed mainly of anhedral mosaic of medium crystalline dolomite.
778	L379	22	PU	Biomicrite	Rather coarsely recrystallized fossil remains are cemented by microcrystalline calcite, and discrete rhombs of dolomite replacing coarse calcite selectively.
781	L386	22	PU	Biomicrite	Spherical radiolarian shell and spine, which are replaced perfectly by calcite, are cemented by microcrystalline calcite.
782	L390	22	PU	Dolomite	Very fine (less than 0.1 mm) anhedral mosaic of dolomite.
792	L454	10	PU	Sandstone	Medium grained subangular quartz (nearly 75 per cent) and detrital grains of chert (about 20 per cent) are cemented by silica and clary matter.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
796	L481	10	CG	Gabbro	Rock shows granular and ophitic texture, and is composed of plagioclase (euhedral - subhedral, less than 2.74 x 0.60 mm, An=82 - 70), brown hornblende (less than 0.68 x 0.42 mm), green hornblende (less than 0.25 x 0.08 mm), augite (subhedral, 0.30 x 0.16 - 0.50 x 1.37 mm, CAZ 42°), olivine (anhedral, less than 0.40 x 0.18 mm, altered to serpentine along cracks) and magnetite (subhedral or anhedral, 0.42 x 0.14 - 0.08 x 0.07 mm).
798	L497	10	TR	Welded tuff	Rock shows porphyritic texture and is composed of anhedral-subhedral quartz, subhedral altered plagioclase, euhedral altered hornbrende and a small quantity of magnetite. Fragments of biotite quartz schist and shale occur in matrix. Matrix consists of volcanic ash, long lenticular pumice and glass showing strong welded structure.
799	L503	22	PU	Dolomite	Composed of rather uniform anhedral mosaic of medium crystalline (less than 0.2 mm) dolomite.
800	L522	9	PU	Dolomite	Rock is originally muddy pelmicrite, and has been partially silicified to calcareous chert. Original texture of pelmicrite is still recognized in dolomite. Still later, calcareous particles have been replaced by rhombs or anhedral mosaic of dolomite nearly perfectly in pelmicrite as well as in chert.
801	L526	9	PU	Dolomite	Original texture of biomicrite is still remained obscurely, although particles have been completely replaced by fine anhedral mosaic of dolomite.
802	L610	23	CH	Sandy shale	Fine to very fine angular grains of detrital quartz and calcite grains are cemented by red colored calcareous silty matrix.
803	L614	22	PU	Brecciatted Dolomite	Medium crystalline dolomite breccias are cemented by coarsely crystalline calcite veins.
834	M493	4	PU	Biomicrite	Small fragmental shells of foraminifera and ostracods, and less than 10 per cent of very fine grained detrital quartz are cemented by microcrystalline calcite.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
841	P321	8	CG	Granite	Rock shows coarse granular texture and is composed of quartz (anhedral, many bubbles), alkali feldspar(fresh perthite, altered orthoclase) and muscovite (anhedral, less than 4.97 x 2.06 mm). Sphene occurs as accessory mineral.
842	P323	8	TR	Granite	Rock shows granular texture and composed of quartz (anhedral, 1.54 x 0.67 - 0.16 x 0.12 mm), alkali feldspar (subhedral or anhedral, 1.70 x 1.02 - 0.25 x 0.12 mm, mainly microcline) and biotite (anhedral, 0.30 x 0.26 - 0.08 x 0.03 mm, X=pale yellow, Z=greenish brown, partially altered to chlorite). Anhedral sphene occurs as accessory mineral.
852	P521	10	TR	Welded tuff	Quartz (subhedral, less than 0.17 x 0.08 mm), plagioclase (euhedral or subhedral, 1.34 x 0.88 - 0.13 x 0.05 mm, altered to clay perfectly), hornblende (euhedral or subhedral, less than 0.18 x 0.10 mm, black ghost crystal, sericite occurs in marginal part) and biotite (subhedral, only one, 0.84 x 0.17 mm, inner part is sericite, marginal part is black). Matrix shows strong welded and consists of many recrystallized tiny quartz and volcanic pale gray ash.
855	P555	8	TR	Quartz porphry	Rock shows porphyritic texture and is composed mainly of quartz (subhedral, 1.54 x 1.04 - 0.20 x 0.16 mm) and hornblende (euhedral, less than 0.14 x 0.08 mm, marginal part black and inner part sericite due to alteration). Zoisite from plagioclase and calcite occur as secondary mineral. Groundmass is fine net texture and wholly glass, consists of fine aggregation of tiny quartz grain,and pale gray clay by weak carbonitization and silicification.
857	P562	8	PU	Dolomite	Composed of finely crystalline anhedral mosaic of dolomite.
858	P563	8	PU	Chert	Rock is originally limestone with sponge spicules, and is partially silicified to calcareous chert. Still later, calcareous particles are replaced complately by rhombs of dolomite.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
859	P565	8	TR	Quartz porphyry	Rock shows porphyritic texture and composed mainly of quartz (subhedral or anhedral), alkali feldspar (euhedral or subhedral, altered to sericite perfectly), biotite (subhedral, perfectly decomposed), and plagioclase (subhedral, perfectly decomposed). Groundmass is wholly glass, and includes many tiny quartz and sericite with silicification or sericitization.
867	S307	21	TR	Aplitic Rock	Rock is strongly kaolinitized and silicified. Alkali feldspar (subhedral, 2.40 x 1.85 - 0.38 x 0.30 mm), plagioclase (euhedral, 2.01 x 0.80 - 0.42 x 0.21 mm) and quartz (anhedral, less than 1.40 x 0.80 mm) occurs as relic minerals. Only one small zircon is recognized. Recrystallized fine quartz occurs in whole section.
875	S322-B	21	PU	Limestone	Original texture of biomicrite is remained obscurely, but particles are recrystallized to rather coarsely crystalline calcite.
881	S343	22	PU	Ore bearing Dolomite	Coarse grained subhedral or anhedral mosaic of dolomite with a few smithsonite derived from sphalerite. Sphalerite is light brown in color but very rare. The refractive index of smithsonite is higher than that of dolomite.
883	S346	22	PU	Ore bearing Dolomite	Medium to coarse grained subhedral mosaic of dolomite with a few smithsonite derived from sphalerite. Sphalerite is light brown in color and exists along fracture or fissure. Almost sphalerite is replaced by smithsonite.
888	S351	22	PU	Ore bearing Dolomite	Medium to coarse grained subhedral mosaic of dolomite. Sphalerite is rarely observed along fissure or fracture but is almostly replaced by zinc carbonate, smithsonite.
892	A339	Hc	TV	Granite	Rock shows granular texture and composed mainly of quartz (subhedral - anhedral, 1.70 x 1.55 - 0.13 x 0.11 mm), plagioclase (subhedral, 1.42 x 1.10 - 0.51 x 0.25 mm, altered to fine mixture of clay mineral and sericite), and alkali feldspar (euhedral or subhedral, up to 0.68 x 0.51 mm, altered to clay and sericite perfectly). Mafic minerals are a small quantity of muscovite (anhedral, 0.77 x 0.16 - 0.20 x 0.06 mm) and biotite (anhedral, less than 0.16 x 0.03 mm), decomposed to sericite mixture. Hematite occurs as secondary mineral.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
893	A381	Sc	PU	Pelmicrite	Original rock is nearly 30 per cent of very fine grained detrital quartz and more than 50 per cent of pellets cemented by microcrystalline calcite. Micritic matrix and pellets are changed to finely crystalline anhedral mosaic of calcite by recrystallization, with scattered rhombs of dolomite.
894	A386	Sc	PU	Limestone	Original rock is sandy pelmicrite as nearly same as A 381. Original texture is still recognized although particles are replaced perfectly by fine anhedral mosaic of dolomite.
895	C372	Ry	SA	Arkose Sandstone	Very coarse to medium grained subangular quartz(about 55 per cent) and alkali feldspar (nearly 40 per cent, mainly perthite) are cemented by a small quantity of carbonate and clayey matrix.
896	C374	Ry	CH	Limestone	Rock consists wholly of very coarsely recrystallized anhedral mosaic of calcite, although an original texture of thin lamination is still recognized.
897	C379	Ry	TV	Granodiorite	Rock shows granular texture and composed mainly of quartz (anhedral, less than 0.35 x 0.24 mm), alkali feldspar (euhedral subhedral, dirty, 1.64 x 0.72 - 0.44 x 0.30 mm), plagioclase (euhedral or subhedral, less than 1.82 x 0.78 mm) and hornblende (anhedral or subhedral, less than 0.65 x 0.42 mm). Biotite (anhedral, less than 0.49 x 0.011 mm, perfectly altered to green chlorite), apatite (euhedral, less than 0.14 x 0.02 mm) and sphene occur as accessory mineral.
898	I344	TG	PU	Andesitic tuff	Plagioclase (euhedral or subhedral, less than 0.42 x 0.16 mm, altered to mixture of quartz and hydrous iron oxides), quartz (subhedral - euhedral, less than 0.10 mm), zircon (only one, euhedral, 0.04 x 0.01 mm) and phlogopite (subhedral, X=colorless, Z=pale yellow) occur in brown volcanic ash matrix.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
900	P457	Hc	TV	Granite	Rock shows granular texture and composed mainly of quartz (anhedral, 0.25 x 0.16 mm), alkali feldspar (subhedral, mainly perthite, 0.18 x 0.16 mm), plagioclase (subhedral, perfectly altered, less than 0.77 x 0.21 mm) and biotite (subhedral - anhedral, 0.60 x 0.82 - 0.08 x 0.06 mm, bending cleavage). Sphene (anhedral, 0.33 x 0.18 mm) and magnetite (subhedral or anhedral occur as accessory mineral.
901	P458	Hc	TV	Andesite	Rock shows porphyritic texture and perfectly altered. Plagioclase (euhedral or subhedral, 0.34 x 0.13 - 0.16 x 0.06 mm, altered to clay) and hornblende (euhedral or subhedral, black unclear crystal) are phenocrysts. Groundmass consists of mixture of clay minerals, iron hydroxide, and tiny grains of quartz.
903	A346	C13	PC	Diorite	Rock shows granular texture and composed mainly of quartz (subhedral or anhedral, 0.95 x 0.60 - 0.05 x 0.01 mm, catacrastic and mosaic figure by stress), plagioclase (subhedral or nahedral, 1.64 x 0.80 - 0.20 x 0.05 mm, all large crystals altered to fine mixture of sericite and zoicite, small ones are fresh and An=64-58), hornblede (subhedral, 1.00 x 0.42 mm, Z=green, X=greenish brown) and biotite (anhedral, 1.20 x 0.14 mm, X=yellow, Z=pale brown).
909	A388	C14	Mi	Rhyolite	Rock shows glassy and composed mainly of plagioclase (euhedral or subhedral, less than 0.80 x 0.45 mm, perfectly decomposed) and hornblende (subhedral, less than 0.40 x 0.12 mm, gray unclear crystal by perfect alteration). Groundmass encloses many isolated spherulites (less than 0.50 x 0.45 mm).
910	C367	B17	SA	Andesitic tuff	Composed of quartz (subhedral or anhedral, less than 0.25 x 0.18 mm, cataclastic structure or wavey extinction), iron mineral (rounded, less than 0.15 x 0.12 mm) and many calcite cements as secondary mineral. Rarely ash globes (less than 0.18 x 0.19 mm) are recognized. Andesite fragments are observed in pale brown ash matrix.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
912	L441	D13	Mi	Porphyritic rhyolite	Groundmass is composed of very coarse to fine grained quartz (more than 50 per cent, irregular anhedral) and feldspar (about 30 per cent, mostly perthite), which is partly altered to chlorite and sericite. Phenocrysts of quartz are rarely observed.
913	L442	D13	Mi	Dacitic tuff breccia	Rock consists of quartz (subhedral, less than 0.30 x 0.18 mm) alkali feldspar (subhedral, less than 0.48 x 0.20 mm), and plagioclase (eubderal or subhedral, less than 0.45 x 0.22 mm). Matrix is composed of brown or black ash with many subrounded or rounded fragments of pyroxene andesite, acidic andesite, schist, shale, and pumice.
914	L443	D13	PU	Pelmicrite	Pellets, several per cent of fine grained detrital quartz and some fossil fragments (radiolarian and echinoids) are cemented by microcrystalline calcite.
915	L446	D12	PU	Limestone	Coarse to fine anhedral mosaic of calcite, which is originated from crinoidal biomicrite with chert grains.
916	L512	F4	MD	Monzonite	Rock shows granular texture and composed of quartz (anhedral, 0.98 x 0.80 - 0.22 x 0.15 mm), alkali feldspar (subhedral, less than 1.25 x 0.85 mm), plagioclase (subhedral, 0.80 x 0.60 mm ±) and biotite (subhedral, 1.14 x 0.88 mm ±, very weak pleochroism).
917	L514	F4	MD	Granodiorite	Granular texture and composed of quartz (anhedral, 0.21 x 0.21 mm ±), feldspar (all decomposed perfectly), hornblende (subhedral, 1.45 x 0.60 mm ±, X=green, Z=yellow) and biotite (anhedral or subhedral, 1.96 x 0.65 - 0.10 x 0.04 mm, X=pale green, Z=pale brown). Some of mafic minerals occur as embayed crystals.
918	L516	F4	MD	Diorite	Rock shows coarse granular texture, and is composed of quartz (subhedral or anhedral, wavey extinction), feldspar (euhedral - subhedral, perfectly altered to clay mineral), hornblende (perfectly altered to chlorite, anhedral) and a small quantity of magnetite.
919	L517	F4	Mi	Shale	Very fine grained detrital quartz, feldspar, chert and fragments of andesite are cemented by silt and tuffaceous matrix. Tuffaceous matrix is altered distinctly.

Sample No.	Field No.	Locality	Formation	Rock Name	Microscopic Observation
921	P541	E4	Mi	Quartz porphyry	Rock shows porphyritic texture and is composed mainly of quartz (subhedral or anhedral, 2.88 x 1.65 - 0.18 x 0.14 mm), feldspar (euhedral or subhedral, 0.92 x 0.80 - 0.40 x 0.22 mm, fine aggregations of sericite and clay minerals) and hornblende (euhedral, less than 0.21 x 0.14 mm, misty crystals). Groundmass is glassy and altered to fine mixture of clay minerals and sericite.
922	P543	E4	Mi	Dolerite	Rock shows porphyritic texture and is composed mainly of olivine (subhedral or anhedral, 1.58 x 0.70 - 0.35 x 0.21 mm, altered to antigolite perfectly) and augite (subhedral, 1.30 x 1.15 mm, altered to fine mixture of iron ore and plagioclase perfectly) as phenocrysts. Groundmass shows intersertal texture and consists of augite (euhedral, 0.28 x 0.02 mm, C Z=40° - 43°), ilmenite (euhedral prismatic, less than 0.20 x 0.02 mm) and plagioclase (euhedral, less than 0.80 x 0.15 mm, long prismatic, altered to clay minerals).
923	P546	E4	Mi	Porphyrite	Rock shows porphyritic texture, and is composed of plagioclase (euhedral or subhedral, 0.50 x 0.14 - 0.24 x 0.07mm, are altered to recrystallized quartz perfectly) and decomposed mafic mineral (0.25 x 0.20 - 0.08 x 0.06 mm, fine aggregation of iron ore and quartz). Groundmass is very fine mixture of sericite and quartz, and shows fluidal texture partly.
924	P547	P5	PU	Andesitic tuff	Rock shows porphyritic texture and is composed of hornblende (euhedral or subhedral, 0.26 x 0.20mm, unclear crystal, fine aggregation of iron ore and plagioclase) and quartz (subhedral or anhedral, 0.60 x 0.35 - 0.18 x 0.03 mm, wavey extinction). Structure of matrix is not sure, but may be altered the matrix by decomposition and strong silicification or chloritization. It consists of recrystallized fine quartz and chlorite.

A. 1 - 3. Microscopic observation of the polished sections

Sample No.	Field No.	Locality	Rock Name	Reflecting Microscopic Observation
689	A308	8	Dolomite	The specimen is dolomite with pale brown color. Under the ore microscope, besides a few pyrite and iron oxide and/or hydroxide, probably hematite and geothite, opaque mineral is not observed. Hematite occurs as separate grains of 10 to 30 microns in general size or sometimes as grains rimmed by goethite. Pyrite occurs as small individual grain or thin veinlet along the cracks.
690	A309	8	Dolomite	The specimen is pale brown dolomite, appearing quite similar to the specimen A-308. Under the ore microscope, many iron oxide and/or hydroxide grains, 50 to 100 microns in general size, and also irregular shaped veinlet 80 to 150 microns in width,which consist of hematite and goethite, are observed. No galena and no sphalerite is found.
712	C308	4	Dolomite	The specimen is very fine grained dolomitic limestone with dark brown color. Fair number of iron oxide and iron hydroxide grains are observed but sphalerite and galena are not found. Iron hydroxide and oxide grains, possibly being composed of hematite and goethite, occur as small spherular grains of hematite core with goethite rim or as irregular shaped aggregate masses less than 60 microns in size. Very fine grain of pyrite, several microns in size, are also observed.
731	C416	21	Galena bearing dolomite	The specimen is galena ore. Several grains of galena up to 7 mm in size are observed megascopically on the polished dolomite surface. Under the microscope, it is observed that galena is replaced by lead carbonate, cerussite, in irregular or network forms. Cerussite is gray in color with strong anisotropism under the crossed nicols and is very similar to gangue dolomite, but it is determined by means of X-ray powder method using a Debye-Scherrer camera. Very a few fine grain of sphalerite, 5 to 20 microns in size, also observed. Some iron hydroxide grains, perhaps goethite with some hematite and relict pyrite, of 30 to 150 microns in size are found. Fine pyrite cube crystals, 5 to 20 microns, are also found. Cu Pb Zn 0.02%, 2.48%, 0.42%

Sample No.	Field No.	Locality	Rock Name	Reflecting Microscopic Observation
755	L305	21	Galena bearing dolomite	The specimen is pale is brown colored dolomite containing some galena crystal grains in megascopically size up to 3 mm. Galena is replaced or rimmed by irregular shaped cerussite as same as Sample C-416. Besides galena, many iron hydroxide grains of 10 to 60 microns in size, may be mainly goethite, are observed. Iron hydroxide veinlet composed of small goethite spherulite, 10 to 20 microns in size, is found along fine crack of dolomite. Fine pyrite grains, 5 to 20 microns, are also found. Cu Pb Zn 11ppm, 7300ppm, 350ppm
762	L319	21	Dark colored	The specimen is limestone of dark brown or black color on polished surface. Under the microscope, galena and sphalerite are not found. Only iron hydroxide grains, masses or network, mainly goethite, and small pyrite are observed. Pyrite sometimes occurs as aggregates of colloform spherulites of 5 to 20 microns. Among goethite frequently fine pyrite relict grains are recognized. Cu Pb Zn 15ppm, 5120ppm, 152ppm
763	L320	21	Limestone (Containing Galena)	The specimen is pale brown colored limestone. A few small grains of galena, 40 microns in max. and 10 to 20 microns in general size, are recognized. Besides galena only goethite with fine pyrite relict inside less than 50 microns and tiny pyrite, 2 to 10 microns, are observed. Some iron hydroxides occur as fine disseminated colloform spherulites. Cu Pb Zn 13ppm, 813ppm, 216ppm
766	L324	21	Dark colored Limestone	The specimen is dark colored limestone. Under the microscope, very few opaque mineral is observed. Several sphalerite grains, 45 microns in maximum and 20 microns in general size, and only one fine galena of 15 × 35 microns are found. Goethite, 5 to 25 microns, and tiny pyrite, 3 to 10 microns, also seen separately. Cu Pb Zn 4ppm, 414ppm, 690ppm

Sample No.	Field No.	Locality	Rock Name	Reflecting Microscopic Observation
768	L329	21	Dark colored Limestone	The specimen is limestone with dark brown or black color on polished surface. Opaque mineral is just a few. A small number of galena less than 40 microns, hematite-like mineral grain, and goethite grains with pyrite relicts less than 120 microns are observed. Cu Pb Zn 12ppm, 424ppm, 556ppm
775	L364	22	Banded dolomite	The specimen is dolomite with pale brownish gray in color. Under the microscope, it is observed that the specimen is composed of rather coarse grains of dolomite and they show sometimes distinct idiomorphic crystal forms. Besides pyrite grains, less than 10 microns, no opaque mineral is observed. Cu Pb Zn 11ppm, 45ppm, 23ppm
776	L376	22	Zebra dolomite	The specimen is dolomite with so-called zebra structure megascopically. As same as Sample L-364 the dark gray part consists of smaller dolomite grains of 100 to 200 microns but the light part is composed of rather large dolomite grains of 400 to 500 microns. Besides a few fine separate grains of sphalerite, some relatively large iron hydroxide masses and several microns of pyrite crystals are observed. Iron hydroxide masses, 400 to 500 microns in size, consist of hematite-like minerals core and encrustered goethite. Cu Pb Zn 3ppm, 38ppm, 18ppm
786	L416	11	Banded dolomite	The specimen is banded dolomite composed of dark brown and pale brown (white) parts. Both of the dark and the white parts consist of dolomite but different in size. In the dark part it is 50 to 150 microns in size but in the white part as large as 500 to 800 microns, sometimes over 1 mm in grain size. Sphalerite grain, 600 × 900 microns in size, and several its veinlets having irregular shape, 20 to 90 microns in width, are observed. Among the white part. A rim of the shphalerite is partly replaced by zinc carbonzte, smithsonite. In the dark brown part considerable many iron oxide or hydroxide grains are observed. They occur in general in form of rectangular and their size is usually several ten microns but sometimes reaches as large as 450 microns. They consist of hematite core and goethite rim or fine mixture of them. Very a few fine galena crystals are found also in the dark part of the specimen. Cu Pb Zn 5ppm, 28ppm, 10ppm

Sample No.	Field No.	Locality	Rock Name	Reflecting Microscopic Observation
791	L437	22	Dark colored dolomite	The specimen is dark brown colored dolomite without any metallic mineral megascopically. Under the microscope, few opaque minerals are observed. Only goethite grains, 60 microns in maximum and 5 to 30 microns in general size and commonly in cubic form, are seen among gangue dolomite. Bright yellow grains of 2 to 5 microns, very similar to gold, are found, but it could not confirmed because of their small size. Cu Pb Zn 2ppm, 34pp, 14ppm
799	L503	22	Dark colored dolomite	The specimen is dark colored dolomite. It is mainly composed of nearly equigranular dolomite crystals of 100 to 250 microns. Besides, iron hydroxide grains, less than 60 microns, fine separate grains of sphalerite 10 to 20 microns, and pyrite of several microns are only observed. Cu Pb Zn 22ppm, 39ppm, 20ppm
835	M494	4	Limestone	The specimen is compact limestone with black color. Under the microscope, it is observed that the veinlet, several hundred microns in width and being composed of coarse grain of calcite, is cutting across the fine grain matrix. Among the fine grain matrix, fine iron hydroxide, possibly goethite, and pyrite less than 10 microns are observed. Sometimes hematite grain rimmed by goethite reaches as large as 40 microns. Only a few grains of sphalerite, less than 20 microns in size, are found beside or in the veinlet of coarse grain of calcite.
836	M495	4	Limestone	The specimen is compact limestone with black in color and is very similar appearance megascopically. It consists of very fine grain of calcite. Fairly many separate grains of sphalerite, 100 microns in maximum and 40 to 60 microns in general size, are observed. Most of sphalerite grains are replaced more or less by smithsonite. Very irregular shaped magnetite like minerals, brownish gray color and isotropic, are also found. Sphalerite and magnetite like mineral occur in rather coarse grain of calcite, over 100 microns, than general matrix fine limestone. Iron hydroxide less than 30 microns, usually 10 microns in size, and very fine pyrite grains are also foubd.

Sample No.	Field No.	Locality	Rock Name	Reflecting Microscopic Observation
847	P421	22	Limestone	The specimen is very compact limestone with black color. Under the ore microscope, it is observed that the specimen consists of very fine grains of calcite, 5 to 20 microns in general size. Opaque mineral is very few. Only pyrite, several ten microns or less in size and iron oxide grains are found in fine matrix.
863	P588	8	Limestone	The specimen is rough and porous limestone with brown color. Under the microscope, many cavities or pores are observed and calcite occurs in form of idiomorphic wedge like crystals of 40 to 80 microns in size. Very few galena fine grains are found in cavities of limestone and very fine grains of pyrite, some are spherical in shape, are also observed in cavities. Sphalerite is not found both in microscopic and X-ray powder diffraction.
865	S302	21	Zebra dolomite	The specimen is banded dolomite of deep to light brown in color. Under the microscope, galena and sphalerite are not found among gangue dolomite. In the part of thin veinlet, less than 0.3 mm in width, many hematite with metallic luster occur in form of rectangular or sometimes triangular. They are 250 microns in maximum and 100 to 150 microns in size and generally replaced and rimmed by goethite and also associated with irregular masses or network of iron hydroxides. Though zinc mineral is not recognized, zinc is detected from the part of iron hydroxide masses by EPMA. Cu Pb Zn 10ppm, 230ppm, 910ppm
869	S310	21	Dolomitic limestone	The specimen is dolomitic limestone with light brown in color. Opaque minerals are not so many observed. A few fine grains of galena and pyrite, less than 20 microns are observed. And iron oxide and/or hydroxide grains, less than 50 microns, are also found, however, sphalerite is not observed. By the EPMA examinations, the tiny portions at where zinc is concentrated in considerable amount, are detected, but it is hardly to identify it from calcite matrix under the microscope. It seems to be most possible that zinc exist as fine grains of carbonate, probably smithsonite, however, the existence of smithsonite is not confirmed even by X-ray powder diffraction.

Sample No.	Field No.	Locality	Rock Name	Reflecting Microscopic Observation
875	S322-B	21	Dark colored Limestone	The specimen is limestone with dark brown to black color in polished section. Under the microscope, only a few small separate grains of sphalerite, 10 to 25 microns, and a galena grain, 10 x 40 microns, are found among gangue minerals. Hematite occurs partly in form of thin string of snake-like.
888	S351	22	Zinc Ore	The specimen is sphalerite bearing dolomite. One edge of the polished specimen a brown colored elongated mass, looks iron oxides, is observed megascopically. This portion mainly consists of iron hydroxide and sphalerite. Sphalerite, white with pale brownish tint in reflection color, is replaced by zinc carbonate, smithsonite. Smithsonite shows low reflection behavior as similar to gangue dolomite and then it is very hard to distinguish each other. Replacement of sphalerite by smithsonite progresses considerably and they show "shredded", "island shaped", or "lattice shaped" textures. The grains supposed to be replaced completely by smithsonite are sometimes observed. Iron hydroxide occurs as separate grains, less than 400 microns, of goethite associated with hematite-like mineral and relict pyrite, or as complicated network. Besides them, fine pyrite of 5 to 20 microns in size are found among dolomite. Cu Pb Zn 0.01%, 0.02%, 8.80%
881	S343	22	Zinc Ore	The specimen is sphalerite-bearing pale colored dolomite. Sphalerite is observed megascopically as pale brownish or pale grayish color with semi-metallic luster on the polished section. Under the microscope, sphalerite shows white with faint brownish tint in reflection color and it gives numerous white, yellow, or brownish internal reflection which disturbs isotropic darkness under the crossed nicols. Sphalerite is replaced by smithsonite and they show the textures of "veinlet network", "scratched", "shredded", "island shaped", or "lattice shaped". Smithsonite is gray in reflection color with pleochroism which is very similar to gangue dolomite, however, smithsonite gives characteristic fancy milky yellowish internal reflection under the crossed nicols. As only by the microscopic observation it is difficult to identify smithsonite from dolomite, it was confirmed by the X-ray powder diffraction. Hematite grains, 50 to 100 microns in size, some goethite grains less than 40 microns, and fine pyrite of several microns are found as independent grains among gangue.

Sample No.	Field No.	Locality	Rock Name	Reflecting Microscopic Observation
883	S346	22	Zinc Ore	The specimen is sphalerite-bearing dolomite composed of dark colored and white colored portions. The white part consists of rather larger crystals of dolomite than those in the darker part. Several sphalerite masses up to 5 mm are observed megascopically among dolomite. Under the microscope, sphalerite is replaced by smithsonite just as same as before mentioned samples S-351 and S-343, but the grade of replacement is relatively low in this specimen. A fairly numbers of iron hydroxide grains, probably goethite with fine pyrite relict inside and less than 120 microns in size, are observed, and some of them show cubic form of pseudomorph after pyrite. Fine pyrite less than 20 microns are also found. Cu Pb Zn 0.02%, 0.02%, 22.85%
918	L516	F4	Diorite	The specimen is diorite of pale gray with greenish tint in color on polished surface. Megascopically several pyrite masses up to 2 mm in size are observed. Under the microscope, pyrite occurs as irregular shaped mass in larger grains and as round or granular shape in grains less than several hundred microns. They looks very fresh but some large grains are rimmed by goethite. Besides pyrite, tabular or fine irregular string shaped hematite-like minerals are observed.
922	P543	E4	Andestic tuff	The specimen is pale green andesitic tuff. At the edge of the polished specimen galena masses up to 500 microns in length are observed. Galena, clean white, is not replaced and associates with covellite. Tabular crystals of iron oxide, 50 × 250 microns in maximum and 20-30 × 100-150 microns in general size, are observed being scattered throughout the polished surface of the rock. They look like magnetite in their reflection color but show slightly anisotropism. There are some possibilities to be ilmenite. They are replaced by later goethite.

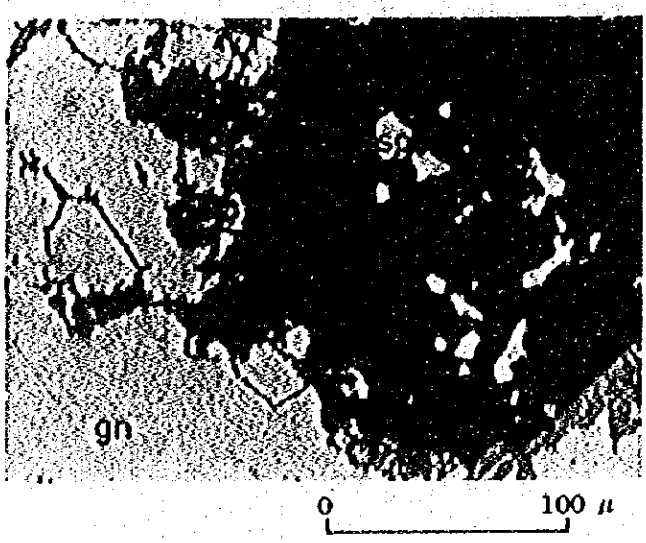
Sample C-416

Galena replaced by network of cerussite.

gn : galena

cer : cerussite



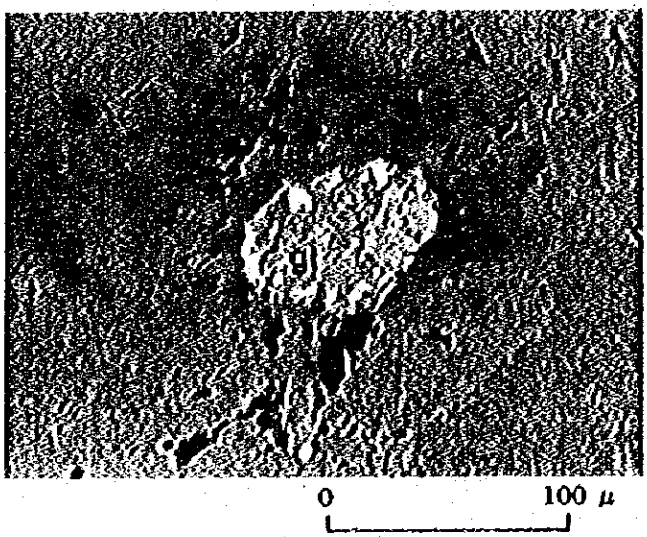
Sample C-416

Fine disseminated grains of sphalerite and galena replaced by cerussite.

gn : galena

cer : cerussite

sp : sphalerite



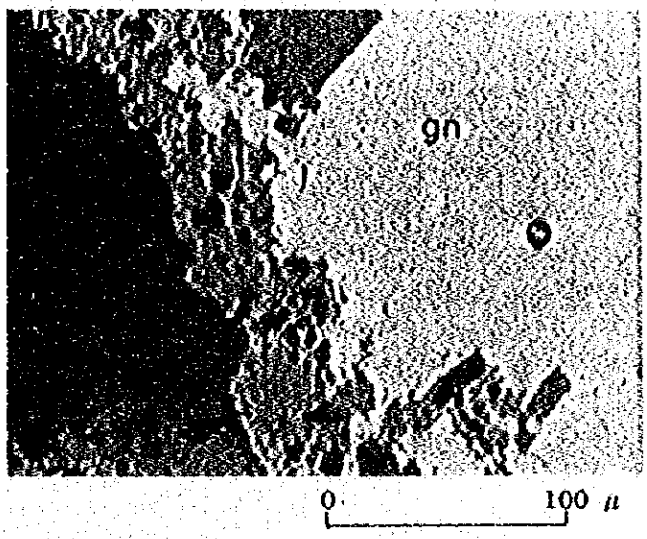
Sample C-416

Iron oxide grain (hematite and goethite?) containing tiny relict pyrite.

hm : hematite

gt : goethite

py : pyrite

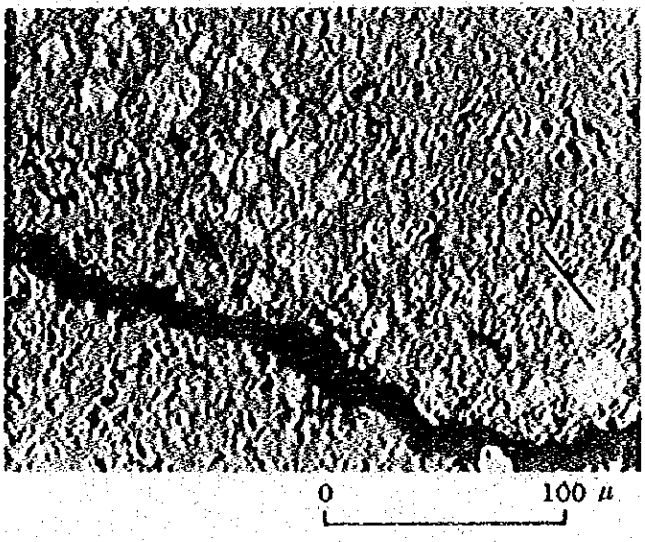


Sample L-305

Galena replaced by cerussite.

gn : galena

cer : cerussite

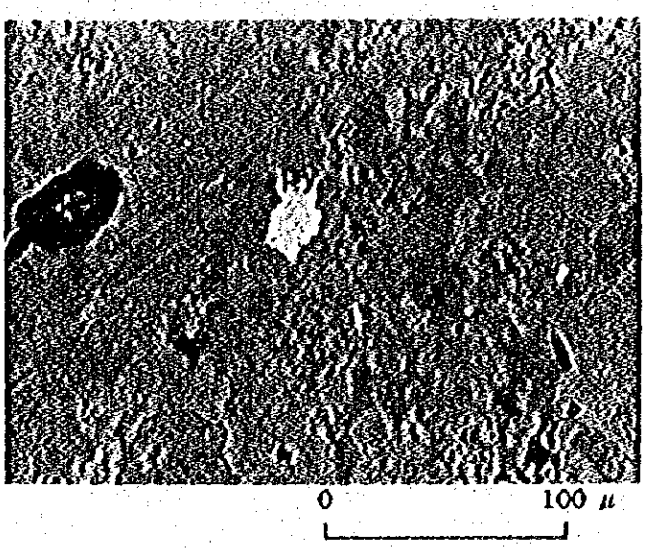


Sample L-305

Iron hydroxide veinlet composed by goethite spherulites along a crack. Pyrite recognized at the center of some goethite.

gt : goethite

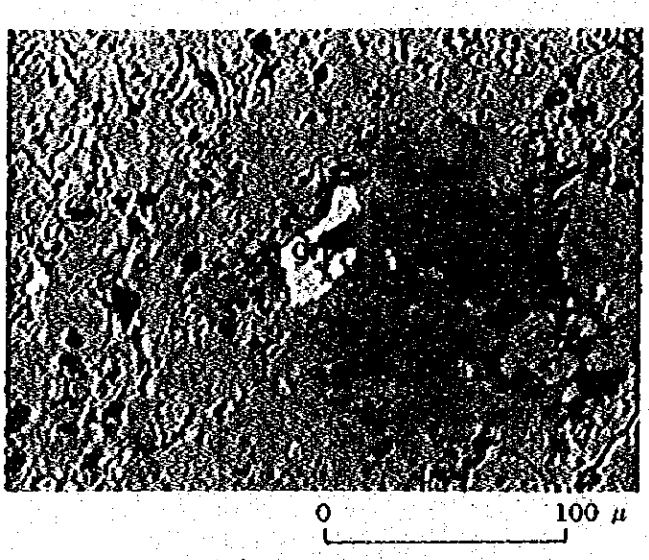
py : pyrite



Sample L-319

An aggregate of fine pyrite.

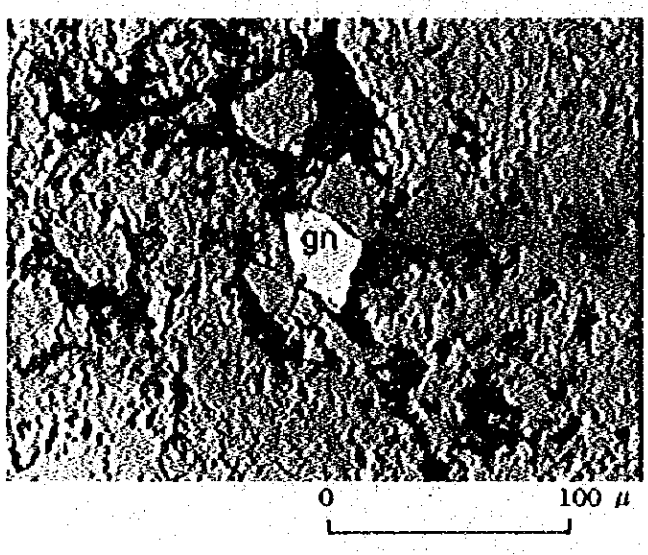
py : pyrite



Sample L-320

Small galena grains.

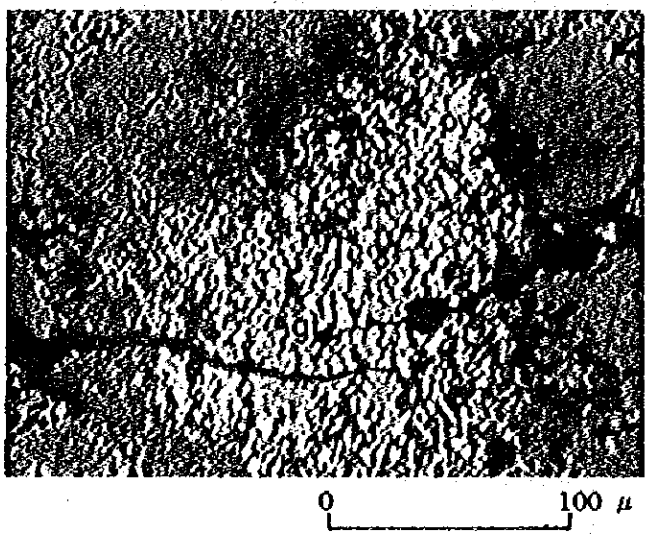
gn : galena



Sample L-320

Galena crystal in a fine crack.

gn : galena

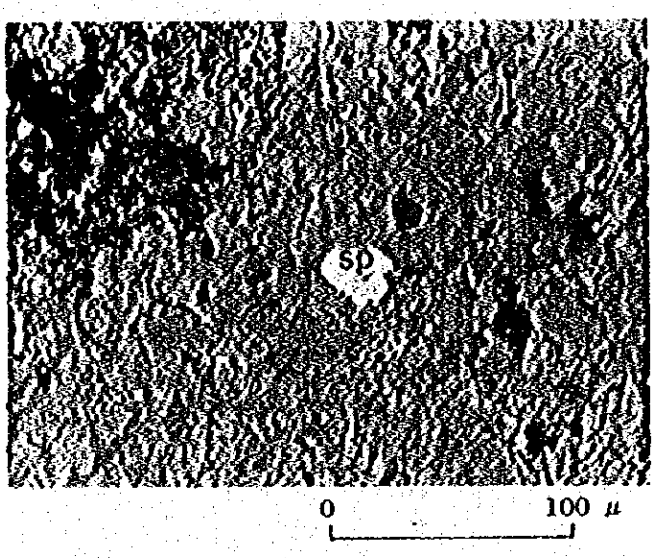


Sample L-320

Fine disseminated spherical goethite with tiny pyrite.

gt : goethite

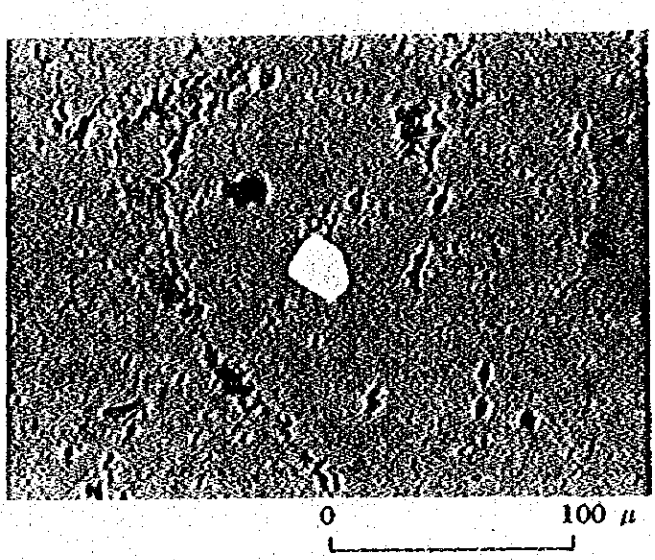
py : pyrite



Sample L-324

Fine sphalerite grain.

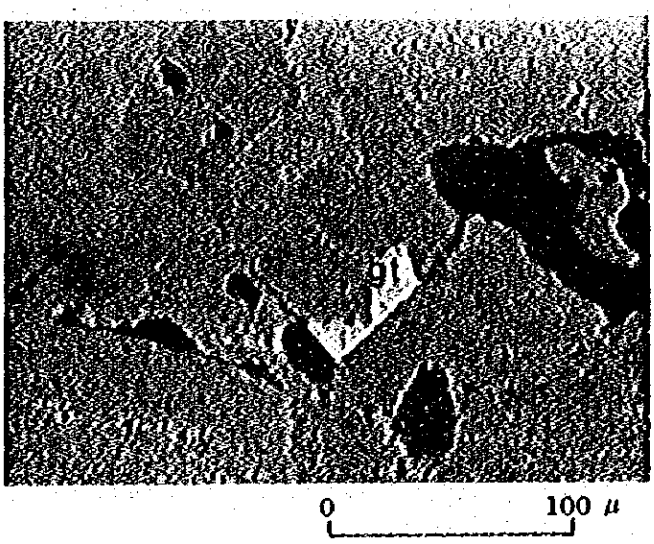
sp : sphalerite



Sample L-364

Idiomorphic pyrite cube crystal.

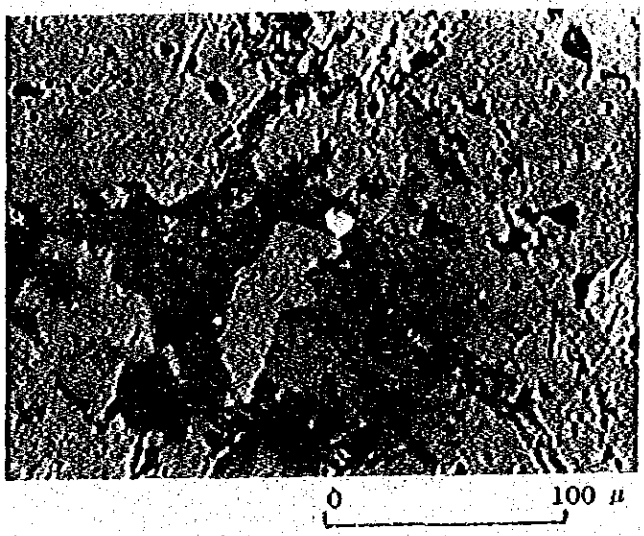
py : pyrite



Sample L-364

Small goethite grain.

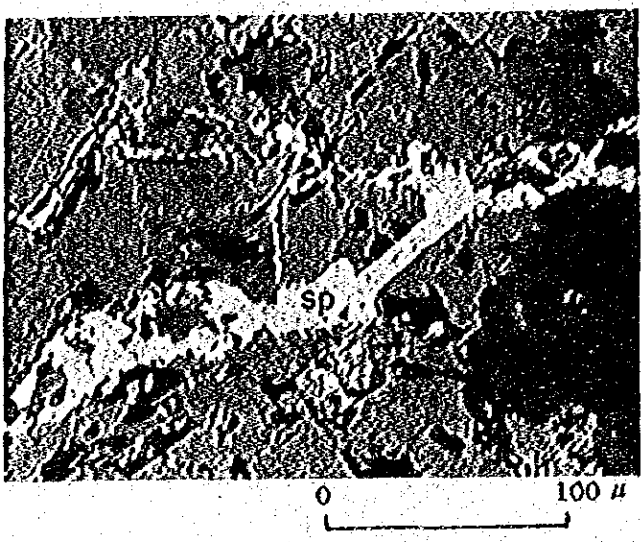
gt : goethite



Sample L-503

Fine sphalerite grain.

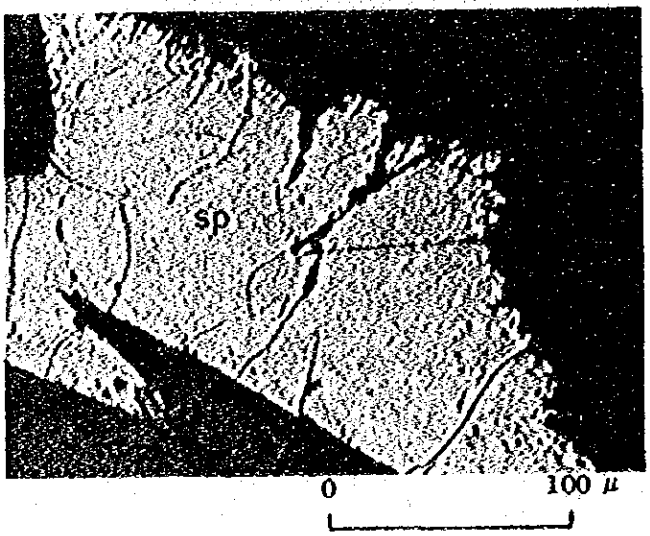
sp : sphalerite



Sample L-416

Sphalerite veinlet in dolomite.

sp : sphalerite

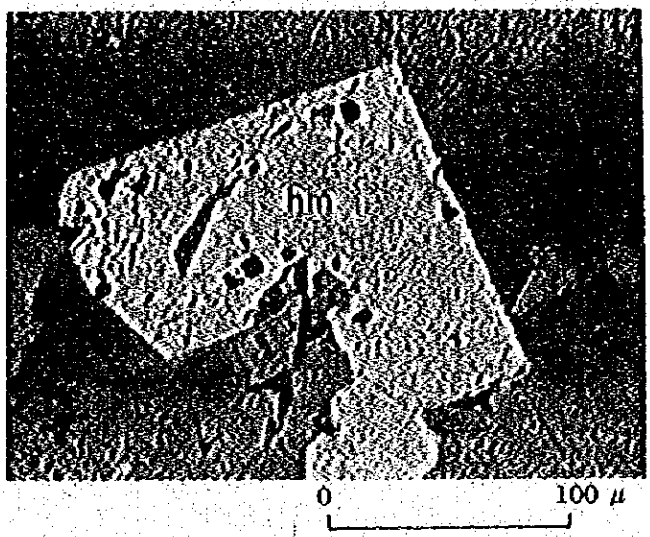


Sample L-416

Sphalerite partially replaced by smithsonite.

sp : sphalerite

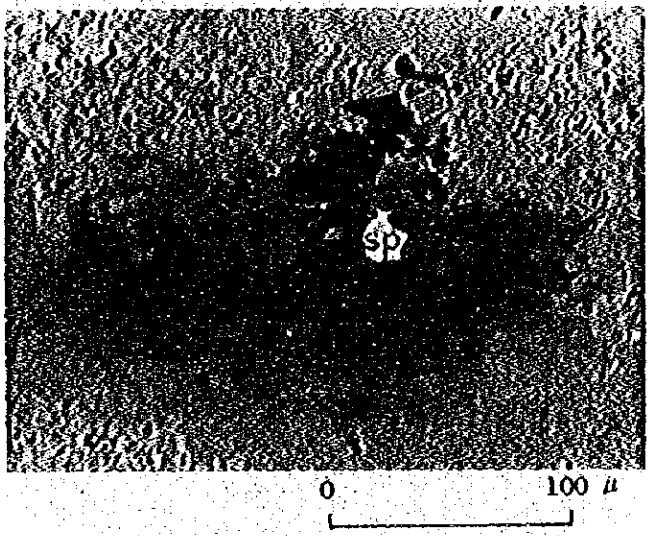
sm : smithsonite



Sample L-416

Hematite rimmed by thin goethite.

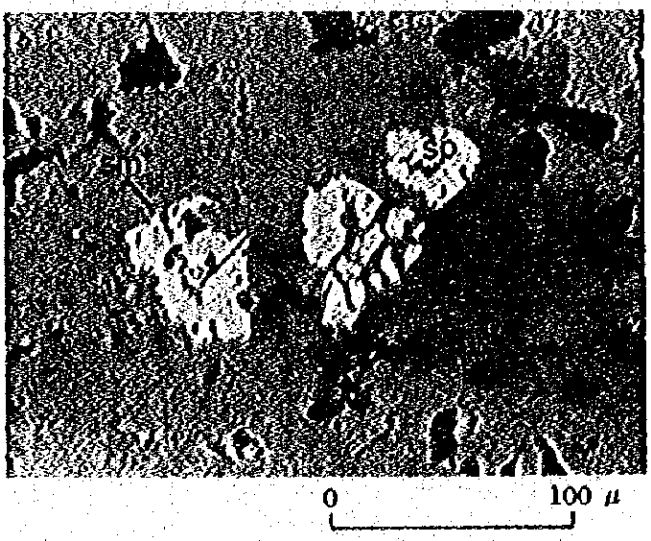
hm : hematite
gt : goethite



Sample M-494

Small sphalerite grain beside coarse grain veinlet of carbonate.

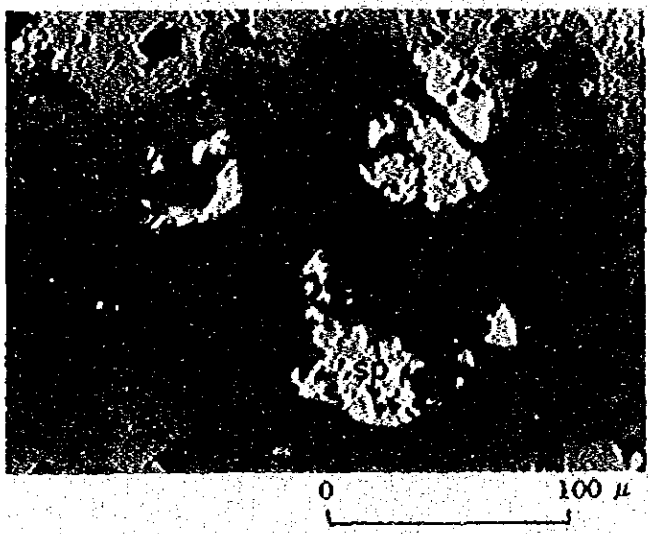
sp : sphalerite
coa-v : coarse grain carbonate veinlet



Sample M-495

Sphalerite grains replaced by smithsonite partly.

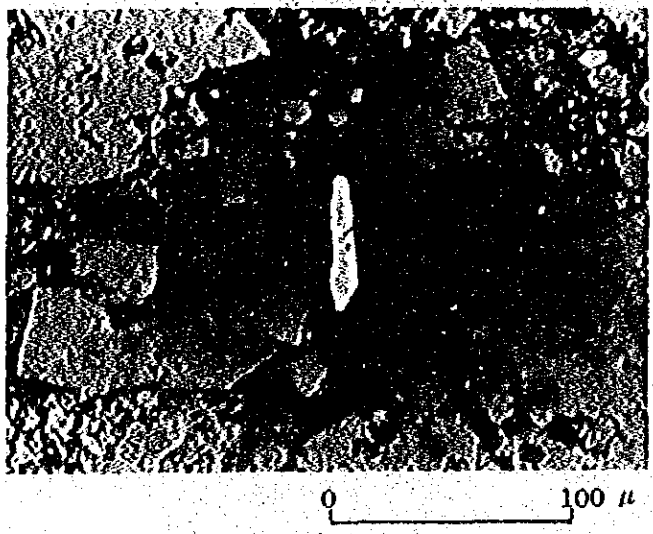
sp : sphalerite
sm : smithsonite



Sample M-495

Sphalerite grains replaced by smithsonite.

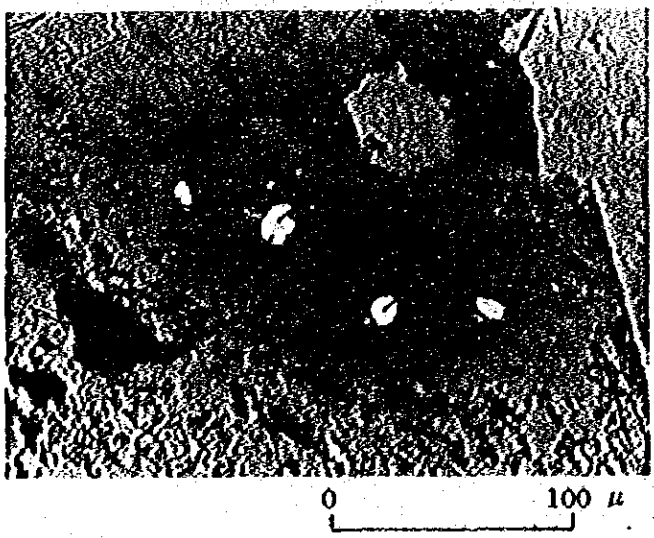
sp : sphalerite
sm : smithsonite



Sample P-588

Galena grain in the hole of porous limestone.

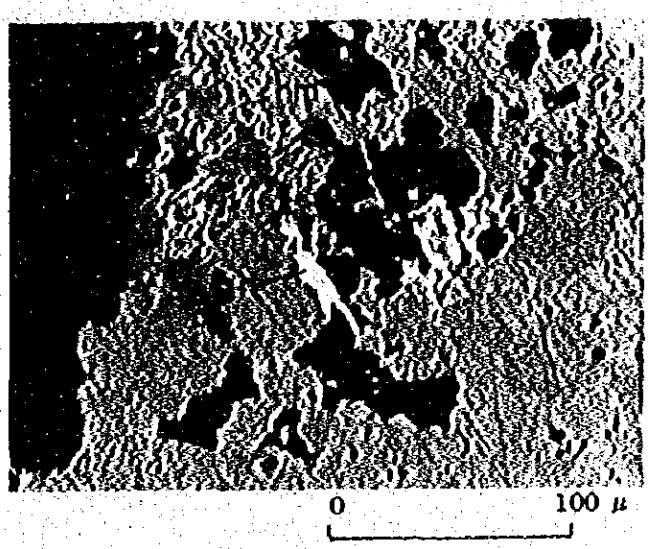
gn : galena



Sample S-310

Pyrite and galena grains.

py : pyrite
gn : galena

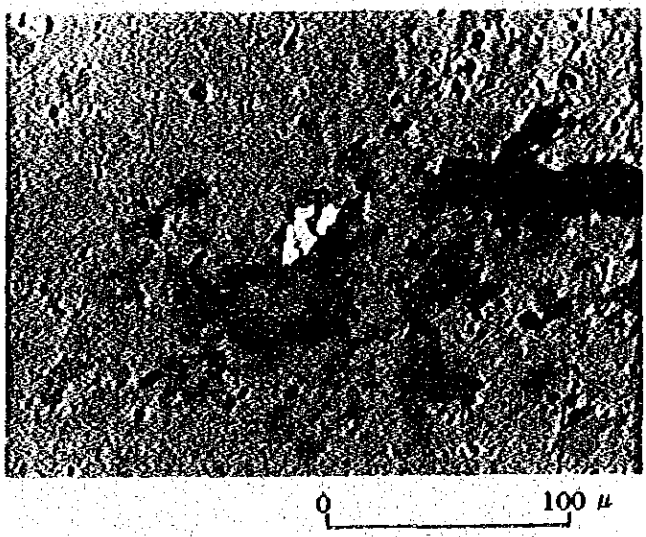


Sample S-322-B

Small galena and snake-like hematite.

gn : galena

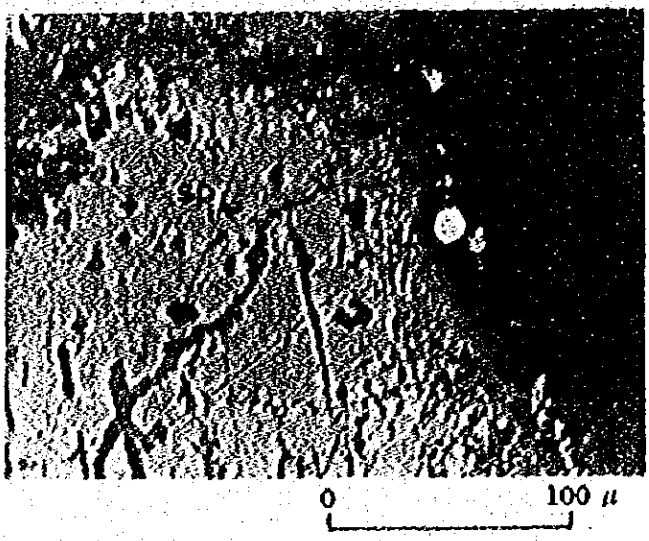
hm : hematite



Sample S-322 B

Fine sphalerite grains.

sp : sphalerite



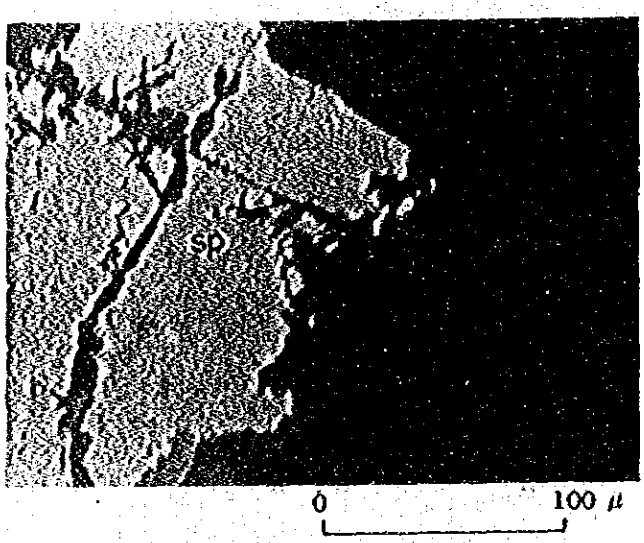
Sample S-346

Sphalerite with smithsonite and fine pyrite grains.

sp : sphalerite

sm : smithsonite

py : pyrite

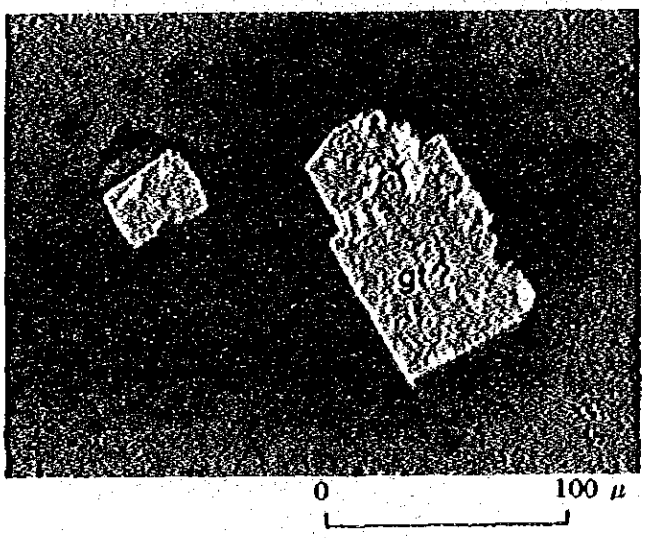


Sample S-343

Sphalerite replaced by smithsonite.

sp : sphalerite

sm : smithsonite

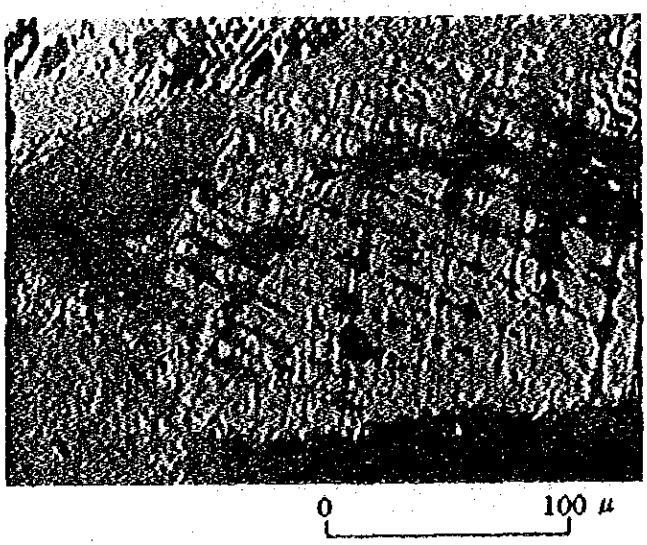


Sample S-343

Iron hydroxide (goethite?) grains with relict pyrite.

gt? : goethite?

py : pyrite



Sample S-351

Sphalerite replaced in lattice shape by smithsonite.

sp : sphalerite

sm : smithsonite

A. I - 5. Chemical composition of ore samples

Constants Used

$\lambda\beta$ = 4.72 x 10^{-10}/year

λe = 0.585 x 10^{-10}/year

K^{40}/K = 1.22 x 10^{-2} atom.%

$$\text{Age} = \frac{1}{\lambda e + \lambda\beta} \ln\left[\frac{\lambda\beta + \lambda e}{\lambda e} \times \frac{Ar^{40}R}{K^{40}} + 1\right]$$

Note : $Ar^{40}R$ refers to radiogenic Ar^{40}.

m.y. refers to millions of years.

Figs. 7a-c. Psiloceratinae gen. et sp. indet.
Right, ventral and left side views of a fragmental specimen, C 323, ×1.

Fig. 8. Camptonectes ? sp.
Left valve of a very small ill-preserved specimen, C 322, ×8.

Figs. 8, 9. Entolium (Entolium sp.)
Left valve of two fragmental specimens, P 503, ×1.5.

Fig. 11. oxytoma (oxytoma) sp.
Left valve of a fragmental specimen, M 451, × 1.4.

Figs. 12-17. Weyla (weyla) sp.

Figs. 12a-c. Steinkern, external mold and gum model of a fragment of right valve, P 503 × 1.2.
Fig. 13. Steinkern of a fragment of right valve, posterior auricle preserved, P 503, × 1.4.
Figs. 14. External mold and gum model of a fragment of right valve, posterior auricle preserved, P 503, × 1.3.
Fig. 15. Steinkern of a fragment of right valve, P 503, × 1.3.
Figs. 16a, b. External mold and gum model of left valve of the same specimen as Fig. 15, P 503, × 1.3.
Figs. 17a, b. External mold and gum model of a fragment of left valve, P 503, × 1.3.

Figs. 18-20. Astarte sp.

Fig. 18. Right valve of a very small specimen, A 376, × 6.
Fig. 19. Left valve of a poorly preserved specimen, A 376, × 2.
Fig. 20. Left valve of ill-preserved small specimen, A 376, × 5.

Figs. 21a, b. Crinoid stem gen. et sp. indet.
Axial and side views of a crinoid stem, A 376, × 6.

Fig. 22. "Pentacrinites" sp.
Axial view of a fragmental stem, L 337, × 6.

Explanation of Plate 3

Figs. 1, 2. Bio-micrite with gastropods shell. A 323.
Many small gastropods and few echinoid fragments are cemented by micritic calcite, ×10. Gastropods and echimoids can not be identified.

Fig. 3. Bio-micrite. A 340.
Muddy micritic limestone with echinoid spine, molluscan shell and intraclasts, deformed rather distinctly by plastic flow, ×10.

Fig. 4. Calcareous shale with molluscan shells. A 345.
Molluscus can not be identified. ×10.

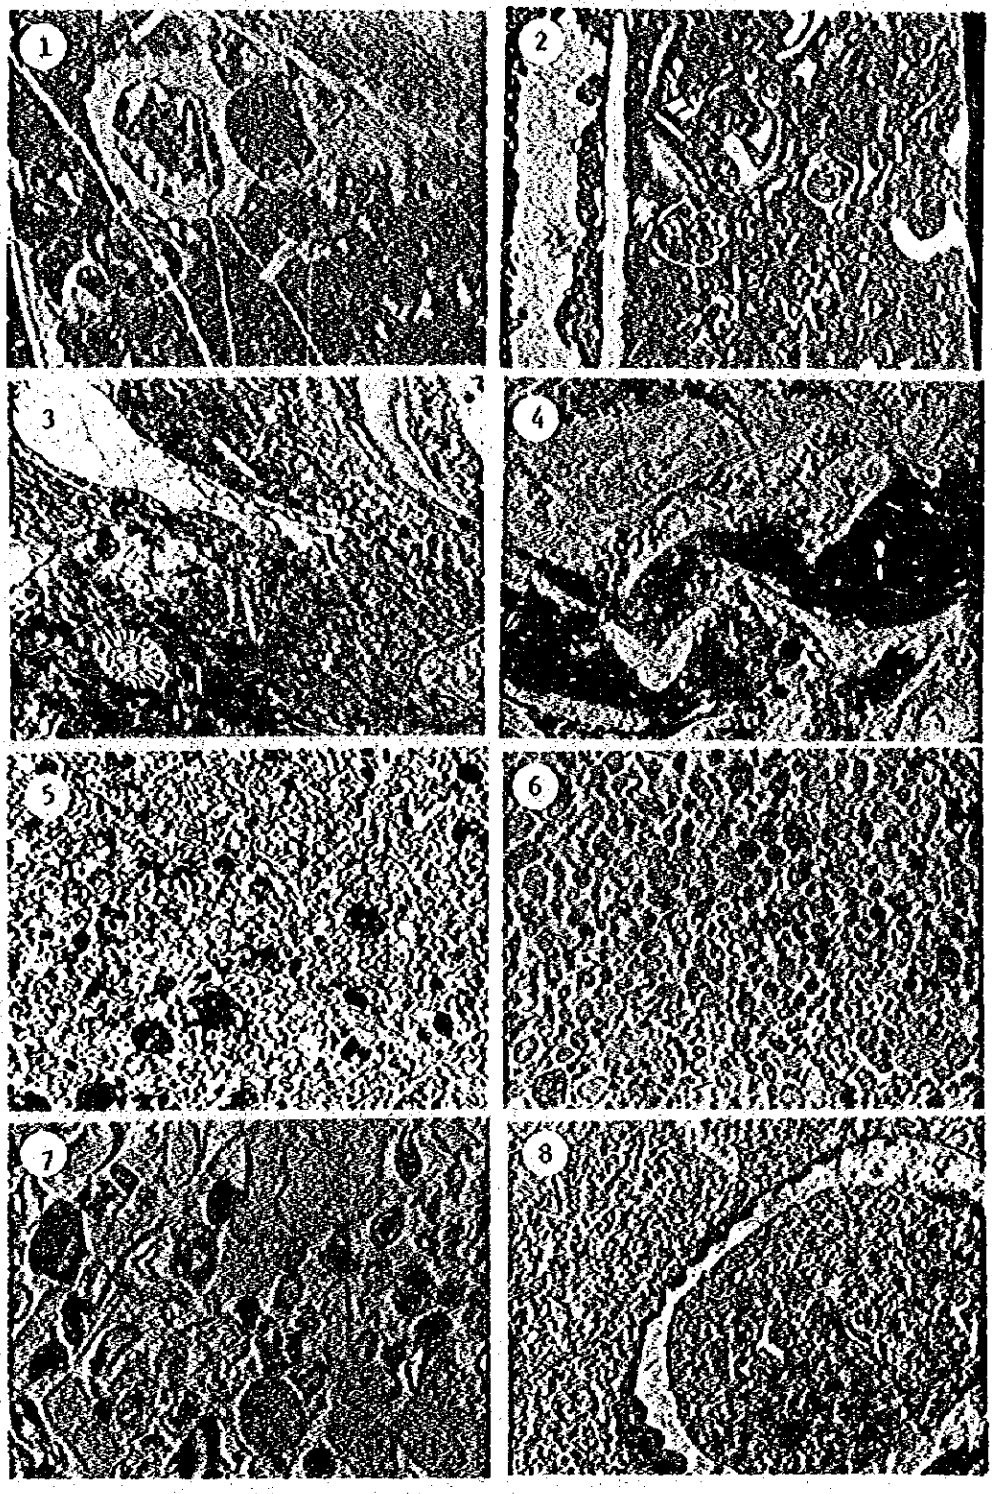
Fig. 5. Calcareous shale with carbonaceous matter. A 352. ×10.

Fig. 6. Slightly dolomitized pelsparite. A 359. ×10.
Fine grained pellets and few fragments of shell are cemented by fine sparry calcite.

Fig. 7. Possiliferous oosparite. A 363. ×10.
Coarse grained intraclasts, echinoid fragments and oolites are cemented by sparry calcite.

Fig. 8. Possiliferous micrite. A 376. ×10.
Sponge spicules and shell fragments are cemented by micritic fine calcite. Sponge and shell can not be identified.

Plate 3



Explanation of Plate 4

Fig. 1. Fossiliferous sandy limestone. L 301. ×10
Small fragments of echinoids, gastropods and bivalves, and very fine grained angular quartz and feldspar are cemented by micritic limestone. Possils can not be identified.

Fig. 2. Distinctly brecciated and silicified oolitic limestone.
L 315. ×10

Fig. 3. Crinoidal sandy limestone. L 319. ×10
Fragments of crinoid stem, intraclastic limestone and several per cent of quartz and rock fragments are cemented by muddy micritic calcite.

Fig. 4. Crinoidal sandy limestone. L 337. ×10
Small fragments of crinoid stem, intraclastic limestone and nearly ten per cent of quartz and rock fragments are cemented by muddy micrite.

Fig. 5. Muddy bio-micrite. L 338. ×10
Small fragments of echinoid spine, molluscan shell and crinoidal stem are cemented by muddy micrite.

Figs. 6, 7. Radiolarian bio-micrite. C 323. ×10

Fig. 6. Very small gastropods and re-crystallized radiolarian remains are cemented by micrite.

Fig. 7. Showing re-crystallized radiolarian remains.

Fig. 8. Muddy limestone with echinoid spine. S 327. ×10
Many fragments of echinoid spine are cemented by muddy micrite.

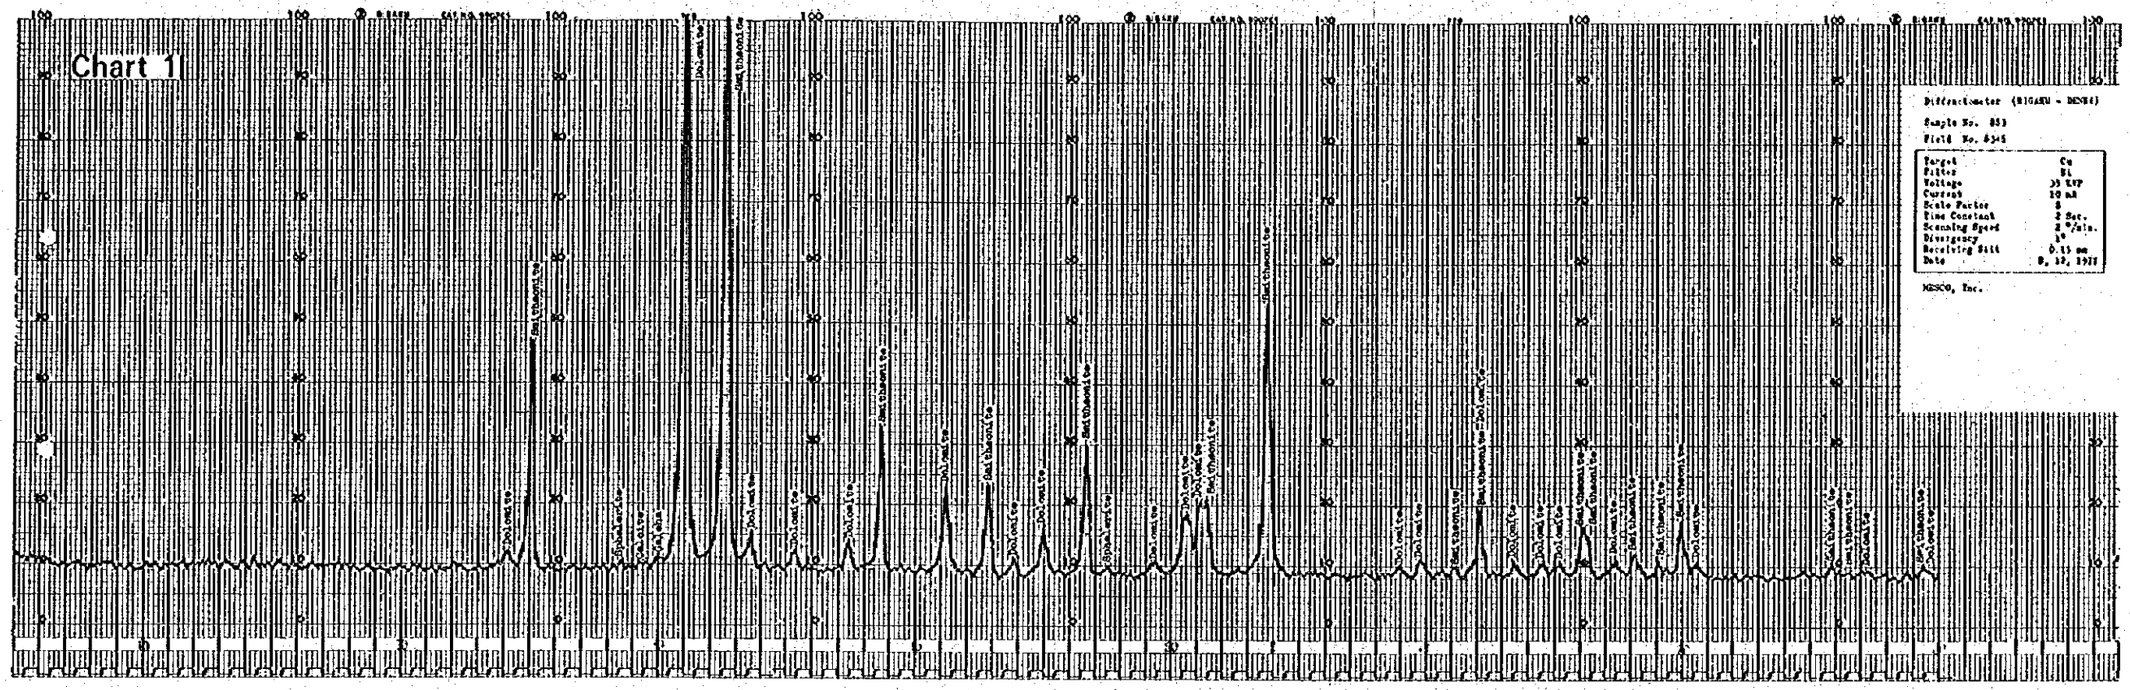
A. I - 11. Charts of X-ray diffraction test



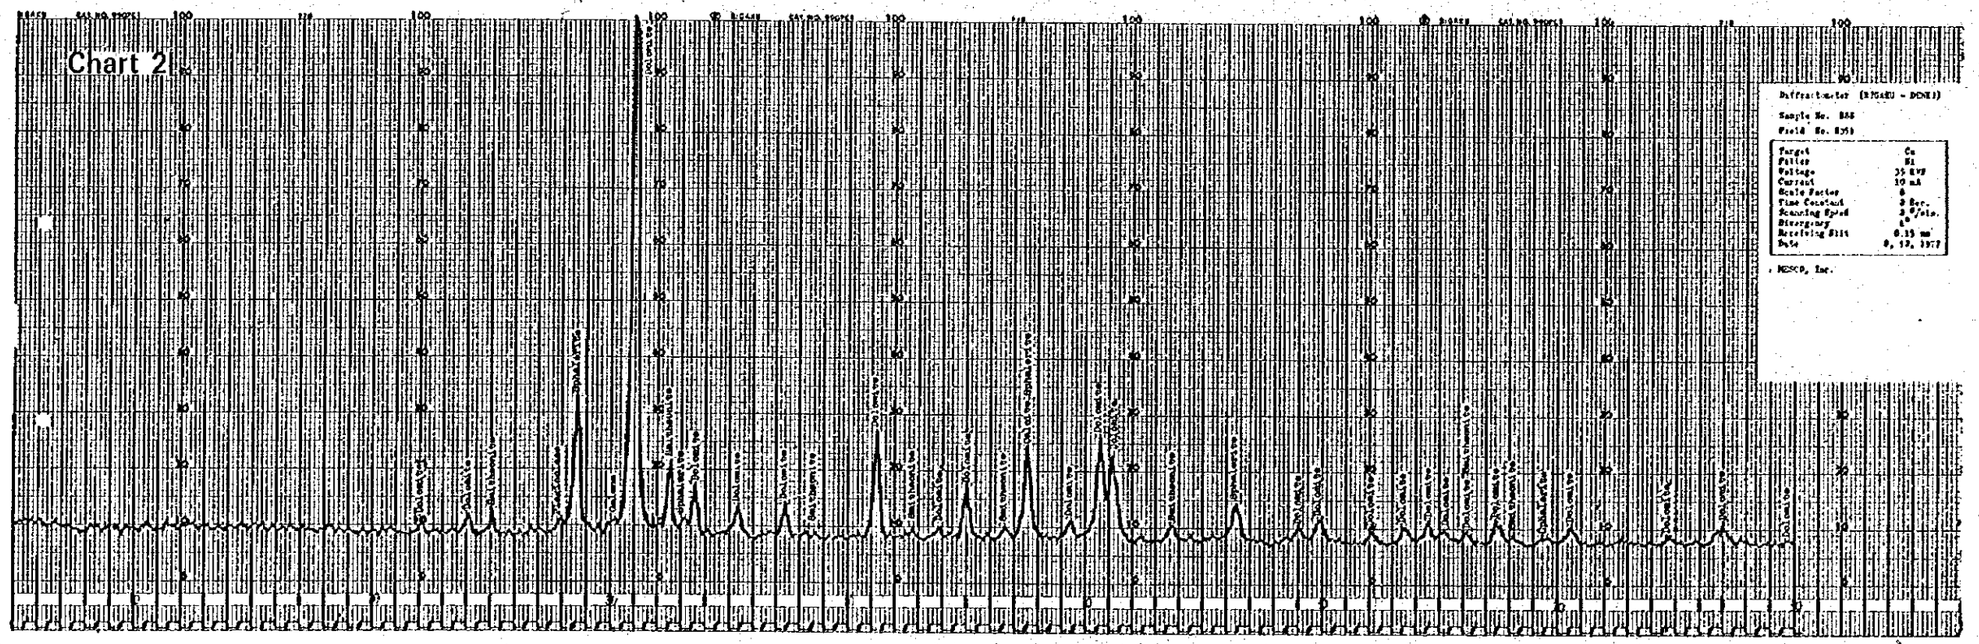


Chart 3

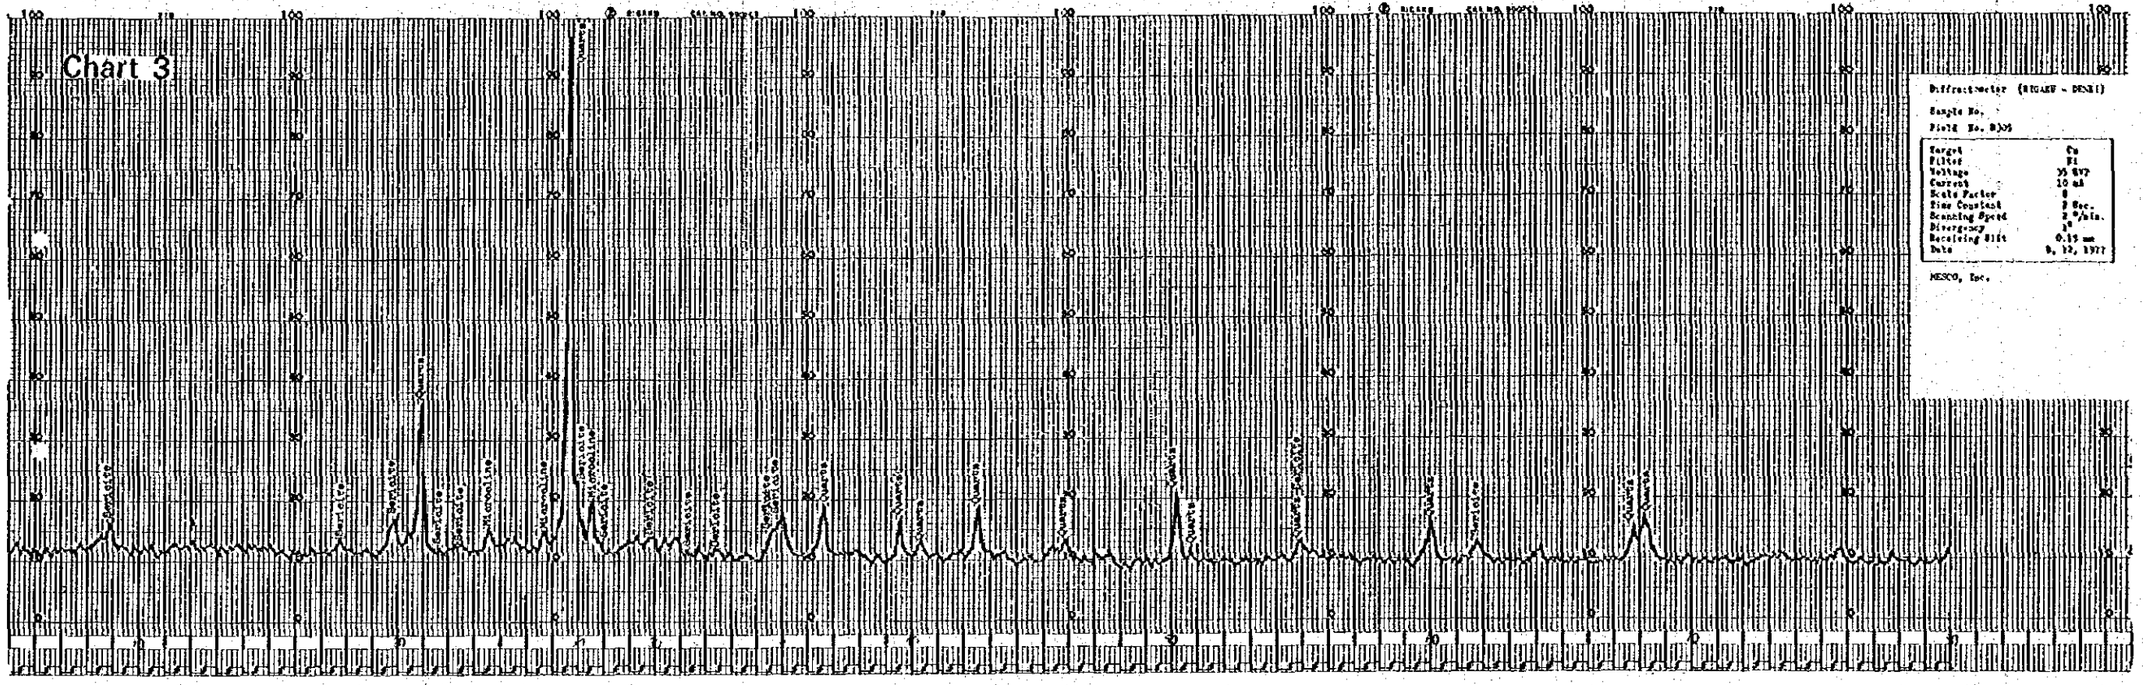

Chart 4

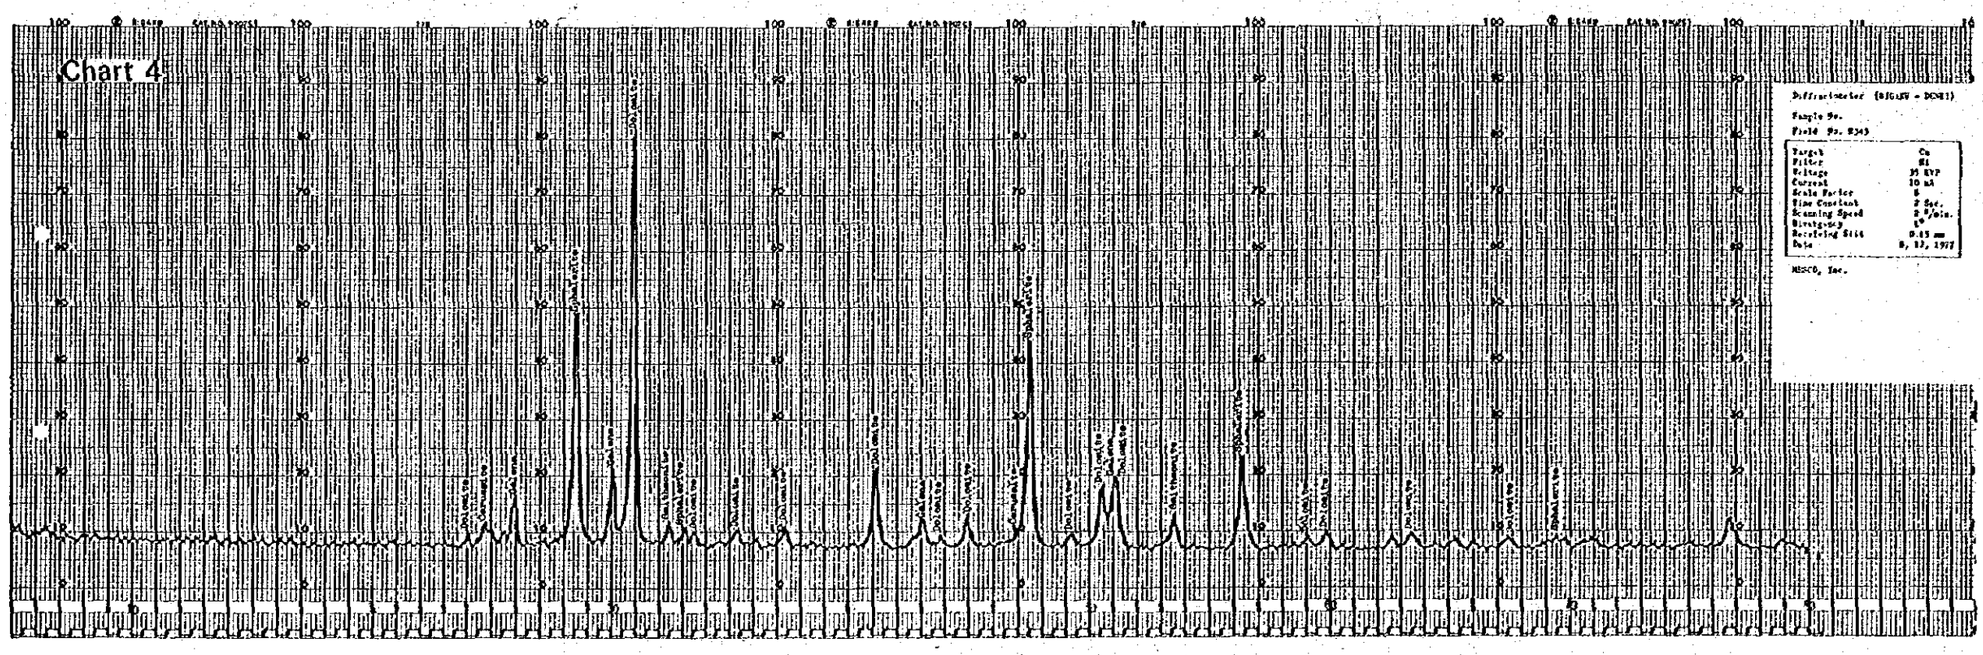

A. I - 12. Flow sheets of chemical analysis

(Cu, Pb, Zn, Ni, Mg)

Sample (1 g) (in 100 - 300 ml conical beaker).

← $HCl + HNO_3 + H_2O$ (3:1:1, 20 ml).

← $HClO_4$ (5 ml).

Evaporation for consolidation.

← (1:1) HCl (8 ml).

Heating for solution.

Cooling (at room temperature).

Transfering in 100 ml beaker.

Shaking.

Filtration (No. 6, 9 cm).

Atomic absorption.

(S)

Sample (0.5 g) (in 100 ~ 300 ml conical beaker).

←— $KClO_4$, about 1 g.

←— HNO_3, 30 ml.

Leaveing out at room temperature.

(reacting to SO_4 for about 30 minutes).

Evaporation for consolidation.

(at lower than 100°C).

Cooling.

←— HCl 5 ml.

←— H_2O 30 ml.

Heating for solution.

Filtration (No. 131, 15 cm, filter paper).

Vashing (hot water added to filtrate makes 200 ml).

Heating (until reaching a boil).

(If Fe is present, it is added a few drops of $NH_2OH.HCl$ (10%) and becomes colourless).

←— $BaCl_2$ (10%) 20 ml.

Heating and leaveing out (for 2 ~ 3 hours).

Filtration (No. 6, 12.5 cm)

Evaporation.

Laying in ashes (at 900 ~ 1,000°C).

Cooling (in desiccator).

Weighing. (S % is $\frac{S}{BaSO_4}$)

A. III - 6. Microscopic observation of the thin sections

Sample No.	Location		Formation	Rock Name	Microscopic Observation
	Hole No.	Depth (m)			
52111	52-1	125.35	Pucara Group	Silicified dolomite	Rock composed of fine to coarse anhedral mosaic of dolomite and about 50% of very fine microcrystalline quartz. Microcrystalline quartz impregnates sporadically and irregularly in mosaic of dolomite. Original rock may be silicified limestone and then calcite is replaced perfectly by dolomite.
52113	52-1	127.35	Pucara Group	Tuffaceous shale	Rock shows granular with weak banded structure. Constituent minerals are recrystallized quartz (very small grain), sericite (very small, fine, and mixed with clay minerals) and hydrous iron ore.
52115	52-1	129.35	Pucara Group	Dolomitized limestone	Original rock may be a fossiliferous limestone composed largely of echinoids debris. Fossil fragments completely recrystallized to coarse anhedral mosaic of calcite, and the matrix replaced by fine grained anhedral mosaic of dolomite by dolomitization.
52123	52-1	210.00	Pucara Group	Recrystallized muddy limestone	Rock consists mainly of rather coarsely recrystallized anhedral mosaic of calcite and muddy materials with silt sized angular detrital quartz. A few shell fragments replaced by very coarse anhedral mosaic of calcite, but can not be identified.
52124	52-1	225.00	Pucara Group	Calcareous fine sandstone	Fine to very fine angular grains of detrital quartz and feldspar cemented by rather coarsely recristallized anhedral mosaic of calcite and clayey materials. Very coarsely recrystallized shell fragments, small spherical carbonaceous matter and spore are scattered in matrix, but can not be distinguishable.
52202	52-2	80.00	Mitu Group	Rhyolitic tuff	Main constituent minerals quartz (β-type, subhedral or anhedral, 1.95 x 1.82–0.40 x 0.32 mm), alkali-feldspar (subhedral, 2.70 x 2.18–0.50 x 0.30 mm, perthite), plagioclase (euhedral or subhedral, less than 0.82 x 0.52 mm, perfectly decomposed; fine mixture of clay minerals and sericite, or changed to calcite) and small quantity of iron ore. Matrix consists of rhyolitic ash and gray colored.

Sample No.	Location		Formation	Rock Name	Microscopic Observation
	Hole No.	Depth (m)			
52204	52-2	140.00	Mitu Group	Rhyolitic tuff	Main constituent minerals quartz (anhedral, 1.86 x 0.50mm - 0.04 x 0.10 mm), plagioclase (euhedral or subhedral, 0.98 x 0.74 mm - 0.40 x 0.15 mm, no zonning, tiny albite twinning, An=24-35, weakly kaolinitized and sericitized), alkali-feldspar (subhedral - anhedral, some of perthite, 1.87 x 0.58-0.50 x 0.18 mm) and iron ore (small quantity, small irregular mass). Calcite (anhedral mass or vein, 2.74 x 2.05-0.20 x 0.15 mm) occurs as secondary mineral. Matrix pale gray, and consists of rhyolitic ash and weakly silicified.
52323	52-3	97.90	Pucara Group	Dolomite	Rock consists wholly of very fine to coarse anhedral mosaic of dolomite. Variation of grain size of mosaic may be originated by micritic matrix and coarse fragments of fossils.
52312	52-3	180.00	Pucara Group	Weakly dolomitized fossiliferous limestone	Fossil fragments consists mainly of echinoids recrystallized to coarse anhedral mosaic of calcite. Original matrix may be micritic limestone with fine grained angular detrital quartz and feldspar. Matrix changes to fine grained anhedral or subhedral mosaic of dolomite by dolomitization.

A. III - 7. Microscopic observation of the polished sections

Sample No.	Location		Rock Name	Microscopic Observations
	Hole No.	Depth (m)		
52108	52-1	115.90	Silty dolomite	The specimen is fine grained calcareous dolomite with many calcite veinlets. Under the ore microscope, many euhedral pyrite grains, 50 to 60 microns in size and aggregates of botryoidal-like grains of 5 to 10 microns are observed. A few fine grains of sphalerite, less than 50 micron in size are recognized among calcite grains.
52109	52-1	116.55	Calcareous dolomite	The specimen is grey dolomite, with many quartz veins, in which are recognized sphalerite with pale brown to yellowish brown in color. Microscopically, sphalerite shows euhedral or subhedral crystal form and more than 1mm in size. Many pyrite grain, mostly euhedral crystal form and about 20-30 microns in size, are found around the sphalerite. Among the calcareous dolomite grains, two forms of pyrite are observed; one is a euhedral crystal, 20 to 30 microns in size; the other is a rounded crystal, a few microns in size.
52110	52-1	124.35	Silty dolomite	The specimen is light grey colerd dolomite with quartz vems. Under the microscopie it is observed that the specimen consists of the fine grains of dolomite (50-60 microns) with many grain of pyrite just as same as before mentioned manner of sample 52109. very few grains of sphalerite, anhedral crystal form and 30-50 microns in size, are found among the dolomite grains. In the quartz vein, sphalerite are observed to be 0.5mm in size, and galena, 1mm in size, are replaced partly by cerussite.
52112	52-1	126.35	Silty dolomite	The specimen is grey dolomite with quartz veins. Megascopically sphalerite grains of 1 to 2 mm in size, are observed. This sphalerite shows euhedral crystal form and accompanies many pyrite as same as sample No. 52109. Among the dolomite crystals many pyrite grains are likely as sample No.52109. A few sphalerite are also recognized.
52114	52-1	128.35	Silty dolomite	The specimen is dolomite with dark grey color. Pyrite is main opeque mineral in two crystal forms as same as sample No.52109. A few grains of sphalerite formed anhedral crystal 10 microns in size are found between the gangue dolomite.
52116	52-1	130.35	Silty dolomite	The specimen is dark gray dolomite containing many fossils' remains. Under the microscope, many subhedral crystals of galena and sphalerite are observed in and/or around dolomitized fossiles. Size of crystals (galena, sphalerite) is about 1mm. In the gangue dolomite, pyrite grains are observed with two crystal forms of sample No.52109. But no sphalerite is observed among the gange dolomite in this specimen.

Sample No.	Location		Rock Name	Microscopic Observations
	Hole No.	Depth (m)		
52118	52-1	140.70	Silicified dolomite	The specimen is dark grey dolomite. Under the microscope, dolomite is composed of nearly equigranular crystals of 50 to 60 microns in diameter. Pyrite grains, mostly euhedral crystal form and 5 to 20 microns in size are found. Several grains of sphalerite, about 10 microns in size are also observed.
52119	52-1	150.90	Muddy dolomite	The specimen shows brownish grey in color. Microscopically many pyrite grains are observed. Only few grains of sphalerite with anhedral crystal form and 30 to 50 microns in size are found in the gangue dolomite.
52312	52-3	180.00	Limestone	The specimen is limestone with dark grey color on polished surface. Under the ore microscope, many grains of shalerite and pyrite are found among the calcite grains. Although a few grains of sphalerite (30-50 microns in size) are recognized as euhedral crystal form in the large grains of calcite that is thought to be recrystallized, they are observed mostly anhedral, 10-20 microns in size among the no recrystallized calcite grains. Pyrite occur as various sizes and crystal forms as same as above-mentiond manners.
52321	52-3	96.50	Limestone	The specimen is grey limestone. Galena is main ore mineral in this specimen. Microscopically it shows subhedral crystal form and is replaced by irregular shaped cerussite. A few pyrite are observed.
52322	52-3	97.50	Fine grained limestone	The specimen shows dark grey in color. Under the microscope, pyrite grains are abundantly observed with euhedral crystal form in shape and sevaral microns in size. And very few grains of sphalerite are also observed.
52408	52-4	120.00	Limestone	The specimen is grey colored limestone. Under the microscope, sphalerite and pyrite are observed. Their occurence is very similar to that of sample 52312.
52107	52-1	105.00	Silty dolomite	The specimen is megascopically very fine grained dolomite composed of gray part and dark grey one. Under the microscope, in the gray part, very few pyrite and sphalerite grains, 30-40 microns in size, are observed but, no sphalerite is found.

A. III - 8. Fossils under microscopic observation

Sample No.	Location		Formation	Rock Name	Fossils	Microscopic Observation
	Hole No.	Depth(m)				
52117	52-1	131.05	Pucara Group	Siliceous shale	Bivalves gen. and sp. indet.	Rock consists mainly of siliceous shale with fragmental shells of bivalves. Shell materials nearly perfectly replaced by anhedral quartz with silicification. Form and surface ornamentations of valves can not be observed.
52401	52-4	15.00	Pucara Group	Fossiliferous pelmicrite	Echinoids and Bivalves gen. and sp. indet.	Coarsely recrystallized shell fragments of echinoids and bivalves, and also echinoid spines cemented by microcrystalline calcite matrix. Irregular sized pellets scattered in micritic matrix. Fossil remains destinguishable only in crossed section.
52414	52-4	154.5	Pucara Group	Fossiliferous pelmicrite	Echinoids and Bivalves gen. and sp. indet.	Nearly same rock as Sample No. 52401, but more abundant of echinoids fragments and finer pellets.
52415	52-4	65.5	Pucara Group	Fossiliferous pelmicrite	Bivalves gen. and sp. indet.	More or less fragmental shells of bivalve cemented by microcrystalline calcite with very fine pellets. Shell materials are replaced by coarsely recrystallized anhedral mosaic of calcite, that is distinguishable only in crossed section. Bivalve seems to be Veneroida but can not be determined.

A. III - 9. Photomicrographs of rocks and fossils

Thin section

Sample No.	Location		Formation	Rock Name
	Hole No.	Depth (m)		
52111	52-1	125.35	Pucara Group	Silicified dolomite
52113	52-1	127.35	Pucara Group	Tuffaceous shale
52117	52-1	131.05	Pucara Group	Siliceous shale
52123	52-1	210.00	Pucara Group	Recrystallized muddy limestone
52124	52-1	225.00	Pucara Group	Calcareous fine sandstone
52312	52-3	180.00	Pucara Group	Weakly dolomitized fossiliferous limestone
52401	52-4	15.00	Pucara Group	Fossiliferous pelmicrite
52414	52-4	65.50	Pucara Group	Fossiliferous pelmicrite
52415	52-4	154.50	Pucara Group	Fossiliferous pelmicrite

Explanation of Plate 1

Fig. 1. 52111 Silicified dolomite.

Anhedral mosaic of dolomite (clouded) and irregularly impregnated microcrystalline quartz (clear), ×32.

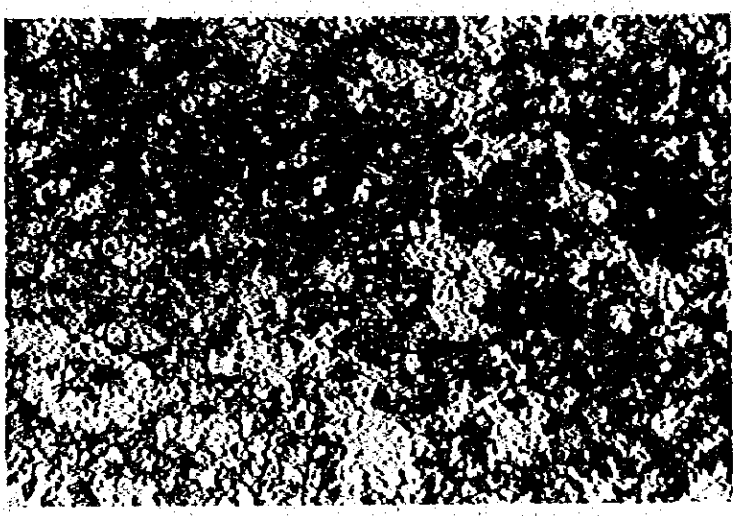
Fig. 2. 52113 Tuffaceous shale.

Recrystallized quartz (clear) sericite and hydrous iron ore (black and gray) showing weak banded structure, ×32.

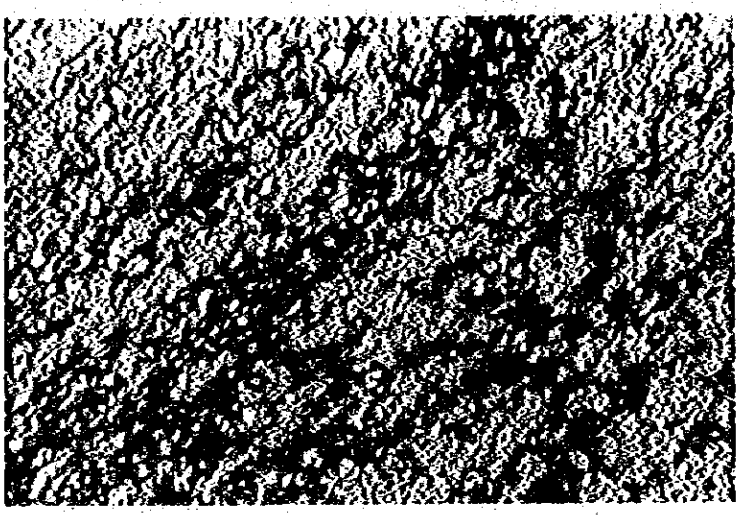
Fig. 3. 52312 Weakly dolomitized fossiliferous limestone.

Coarsely recrystallized fossil fragments (clear, mostly echinoid shell and spine) cemented by weakly dolomitized micritic matrix (dark), ×32.

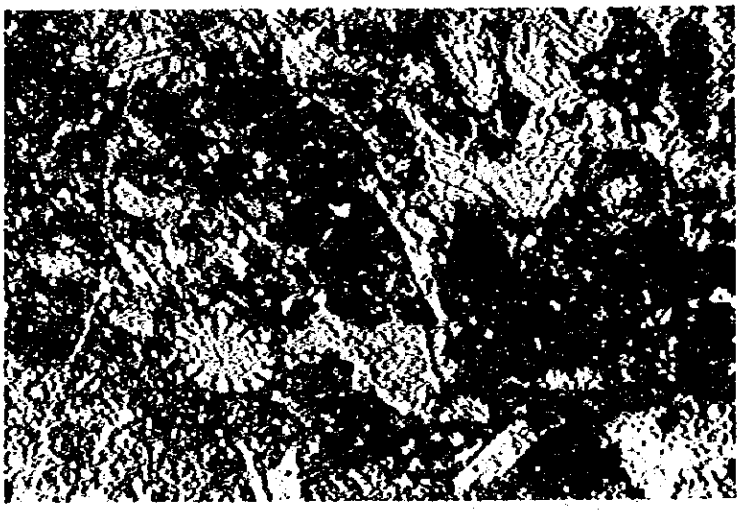
1 - 1



1 - 2



1 - 3



Explanation of Plate 2

Fig. 1. 52117 Bivalve gen. and sp. indet.

Strongly silicified shell (clear) of bivalve observed only in cross section, ×32.

Fig. 2. 52123 Recrystallized muddy limestone.

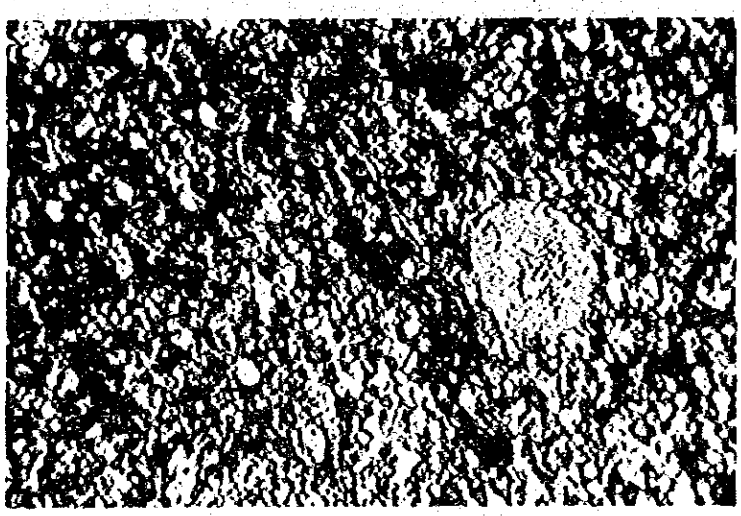
Rather coarsely recrystallized anhedral mosaic of calcite and muddy matrix, with a few fragments of echinoid (clear, circular), ×32.

Fig. 3. 52124 Calcareous fine sandstone with shell fragments and spore.

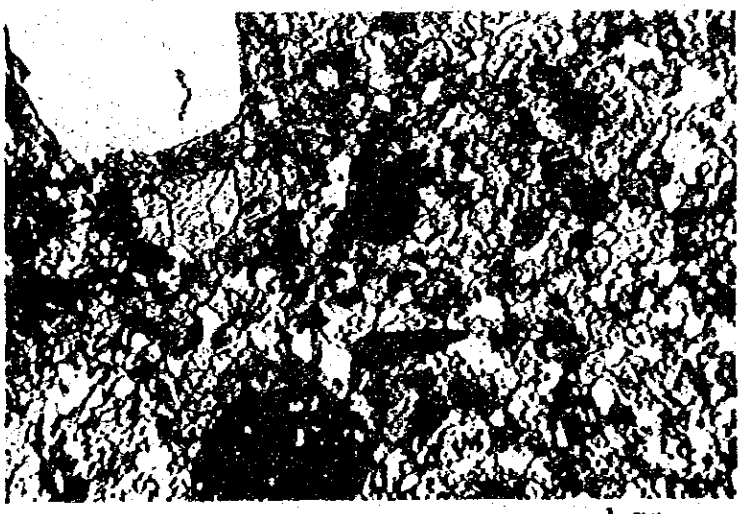
Fine to silt sized angular detrital quartz (clear), very coarsely recrystallized shell fragments (dusty gray), coarsely recrystallized calcite cements and spherical carbonaceous matter (black) cemented by clayey matrix, ×32.

2 - 1

2 - 2



2 - 3



Explanation of Plate 3

Fig. 1. 52401 Possiliferous pelmicrite.

Very coarsely recrystallized shell fragments of echinoid (clear) and echinoid spine (circular) cemented by micritic calcite, ×32.

Fig. 2. 52414 Posilliferous pelmicrite.

Very coarsely recrystallized shell fragments of echinoid (clear) cemented by micritic calcite, ×32.

Fig. 3. 52415 Bivalve gen, and sp. indet.

Coarsely recrystallized shell, seems to be Veneroida, cemented by microcrystalline calcite with very fine pellets, ×32.
