3-7 Drainage Plan

1. Installation positions of drainage sluices

2. Size of facilities

for planning the drainage of landside water, size of facilities can be calculated for trial for the ponding when complete hydrologic data are available. However, as the data are incomplete, the cross section was calculated by an informal method and determined from the local conditions. There are 10 to 15 sluice pipes on the right and left banks in the cross-sectional area of by-pass but most of them are small in size and some of them and burried in the ground due to the flood in 1972. Therefore, it is considered that the pipes have no effect on the function.

In addition, the drainage sluice pipes of \$600 are installed in the national high way of Bacolor. However, as the pipes flowed down by flooding more than 50 cm on the road under conditions in the same year, it is not considered that its size affects the designed areas on the downstream. Therefore, the plan will be developed by nearly neglecting the effects of both roads.

Generally, when the cross sectional area of sluice pipes are to be determined, the following factors should be taken into account.

- (1) The maximum flow velocity in sluice should be controlled within 1.0 to 3.0 m/s.
- (ii) In the case in Japan, take 0.8 to 1.8 $m^2/100$ ha and determine it according to the river slope as follows:

Less than 1/5,000: 0.6 to 0.7 m²/100 ha

1/5,000 to 1/1,500: 1.0 to 1.3 $n^2/100$ ha

More than 1/1,500: 1.5 to 3.0 m²/100 ha

(iii) Tarbot Formula

When rainfall is assumed to be 4 in/hr, $A = C.M^{3/4} (ft^2)$

where, M: Drainage area

C: Topography constants of drainage sections

Steep rocky area: C = 1

Wild hills with gentle slope: 2/3

Width is larger than length: 1/2

Farming land whose length is 3 to 4 times
as large as the width: 1/3

Flat land: 1/5

TABLE III-18

TAIDIN III vo				
	No.1	No.2	No.3	
STA. Point	L. 1+900	R. 1 + 856	R. 7 + 470	
M (km²)	23.5	9.7	2.0	
C	1/5	1/5	1/5	
A (m ²)	11.9	6.4	2.0	
Used Section (m ²)	$2^{\frac{m}{x}} \times 2^{\frac{m}{x}} \times 3$ = 12.0 m ²	$2^{\mathbf{m}} \times 2^{\mathbf{m}} 2$ $= 8.0 \mathbf{m}^2$	61,650 x 1 = 2.14 m ²	

The cross-sectional area will be determined for each point as stated above.

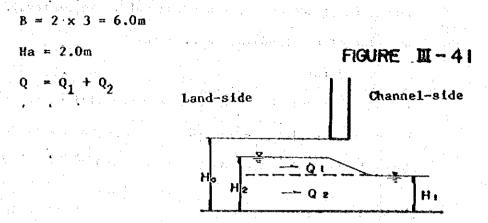

The ponding period of 2 to 3 days is allowable for the cross-sectional area of 0.5 to 1.0m. If the ponding period is above the allowance, the crops will be damaged to extent of nearly no harvest.

3. Landside water drainage plan

The ponding is calculated from a continuous concept that change of ponding volume is a difference between the landside inflow volume and the sluice pipe outflow volume at some time intervals.

Time	ABLE HI-19 Inflow Discharge (m ³ /s)	Outflow Discharge (m ³ /s)	Landside Water Level (n)	Channel Water Level (m)	Inundated Volume (m)
t ₁	· i ₁	•1	h ₁	H ₁	v ₁
t ₂	i ₂	٥2	, , , , , h ₂	H ₂	v ₂

(2) Drainage capacity curve (0 - (h, H) curve)
In the case of sluice pipe, it is calculated from the forms of

When H_1 , H_2 and B are taken as the river side water level, landside water level and width,

$$Q_1 = C_1 \cdot \frac{2}{3}B / 2g(H_2 - H_1) \cdot (H_2 - H_1)$$
 $Q_2 = C_2 \cdot B \cdot / 2g (H_2 - H_1) \cdot H_1$
where, $C_1 = 0.62$ and $C_2 = 0.53$.

Fig. IV-38 is prepared based on the above calculation.

(3) Landside water inflow hydrograph (i - T curve)

From the rainfall strength formula in separately compiled

"Hydrology", the landside inflows are given 48, 61 and

67mm for the pertinent years of 20, 50 and 80.

In this case, the reaching time is 4.0 hrs.

The rational formula is,

$$Q = 0.2778 \text{ f.r.A}$$

and t is put in the form of $t_2 - t_1 = t$

$$v_2 - v_1 = (\frac{i_1 + i_2}{2} - \frac{0_1 + 0_2}{2}) \cdot t$$

where, the landside water ponding volume is expressed with a function of the landside water level h.

$$V = f(h)$$

A drainage volume 0 of the sluice pipes will be decided by the landside water level h and the riverside water level H after determination of the cross-sectional area.

$$0 \approx g(h.8)$$

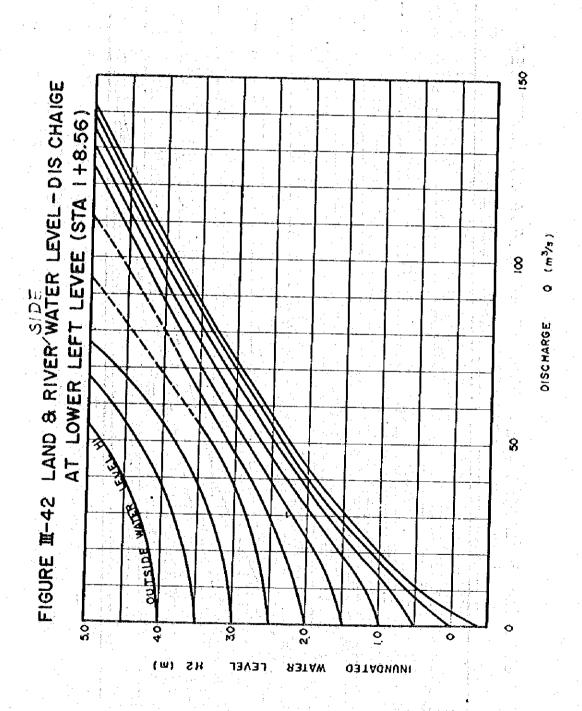

$$f(h_2) - f(h_1) = \left[\frac{1+12}{2} - \frac{g(h_1.H_1) + g(h_2.H_2)}{2} \right] \wedge t$$

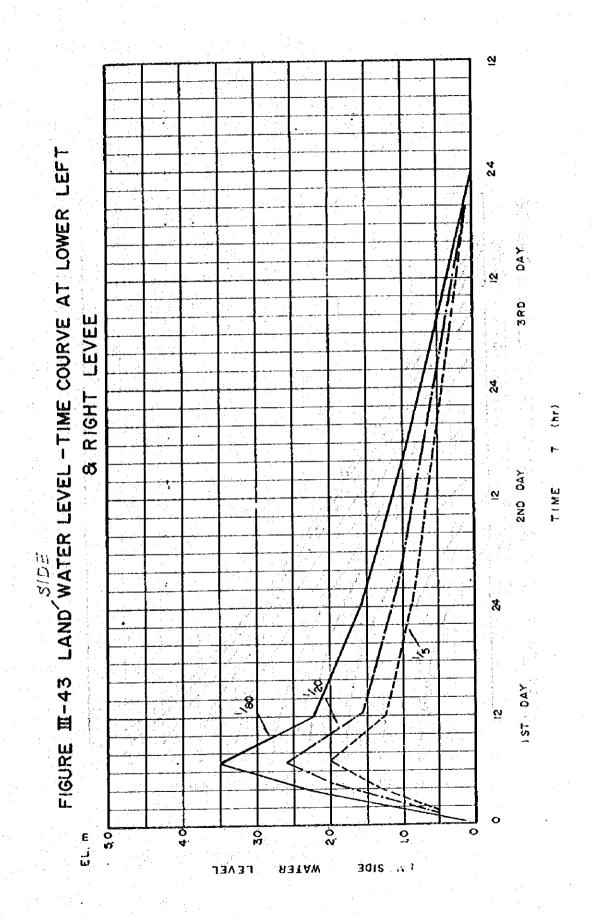

For that purpose, the calculation is developed for

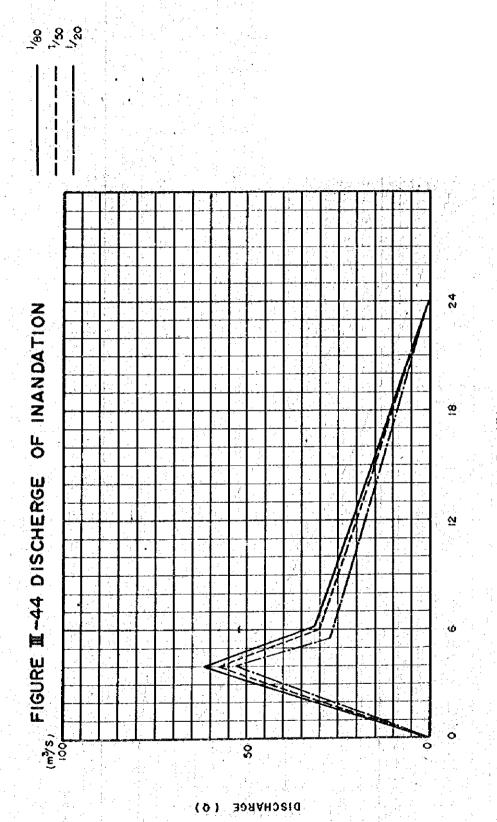

- (1) Riverside water level time curve: H T
- (2) Landside inflow discharge time curve: i T
- (3) Landside water level ponding volume curve: h V
- (4) Drainage capacity curve for sluice pipes: 0 g(h.H) at the a, i point on the left bank of STA1 + 856 in the preceeding item.
 - (1) Riverside water level time curve (H T curve)

 As the data are scarcely available, it is determined to be 7 hrs by using the formulas of Rziha and Kraven and also the slope and distance up to the relevant point.

 From the respective peak levels at the time of 410, 600 and 900m³/s with the relevant probability of 1/5, 1/20 and 1/80, it is assumed that the level will continue for 3 days, and a triangle wave form is converted from the H-Q curve to the H-T curve.

where, Q: Maximum flow (m3/s)

f: Flowout coefficient (=0.6)

r: Average rainfall strength (mm/h) within the reaching hour.

A: Water collecting area (km²)

With regard to the hydrograph, the landside inflow is counted as a daily rainfall in the form of triangle wave by combining the reaching time of 3.5 hrs and the peak time.

(4) Landside water level - flood volume curve (h - V curve)

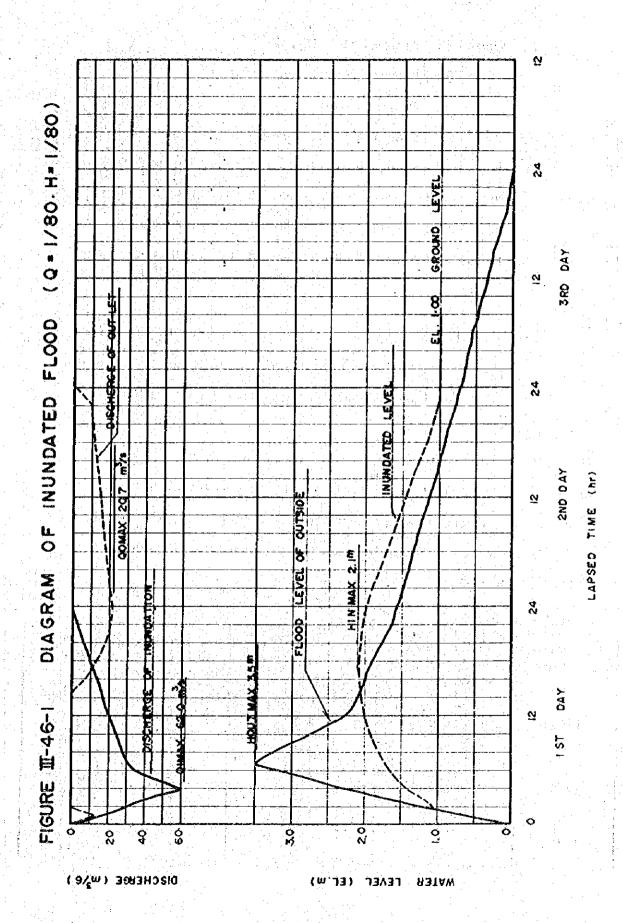

The above-sea-level capacity curve of the relevant point
will be prepared based on the 1/5,000 topographical map.

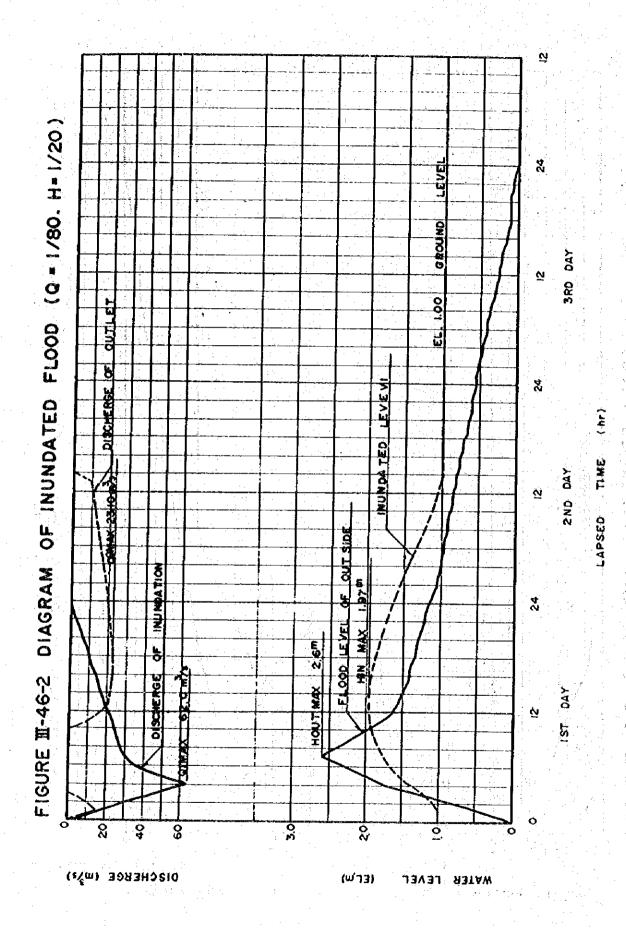

4. Calculation results and conclusion

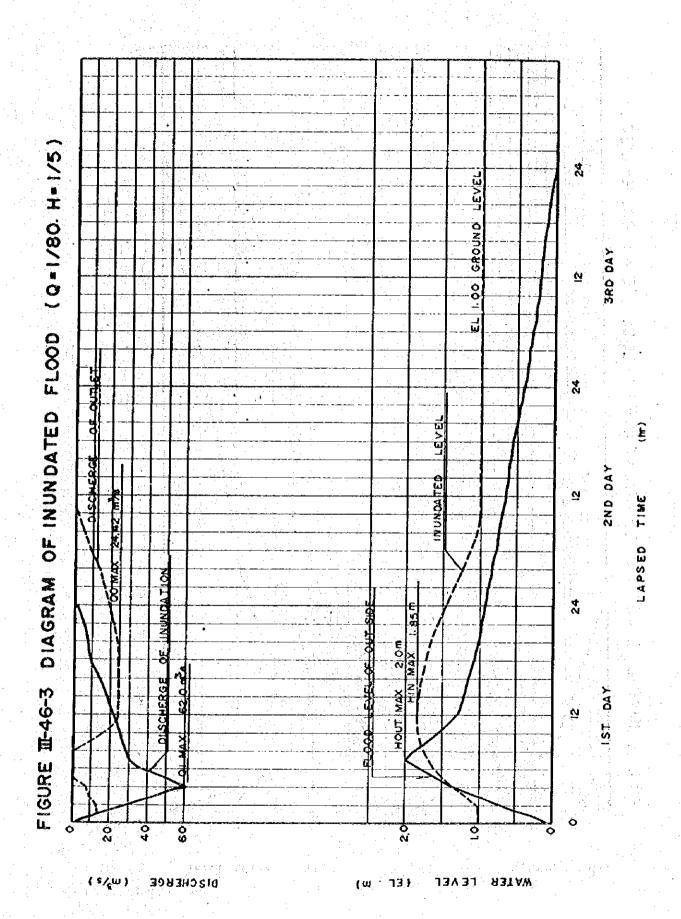

The results of calculation by a computer based on the numerical values in the preceeding item are shown in the tables and figures in the following pages. The results are as summarized in the table below.

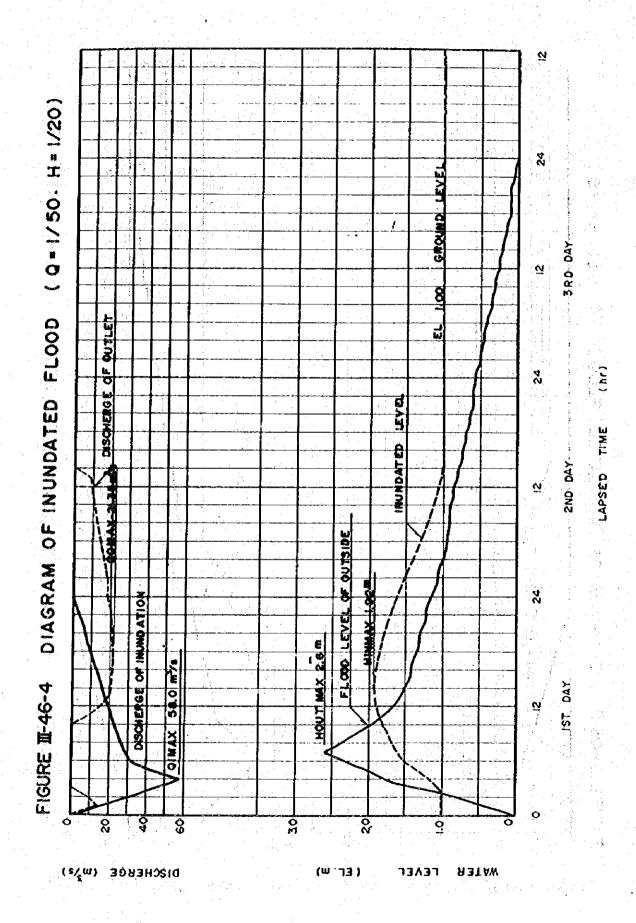

TABLE III- 20

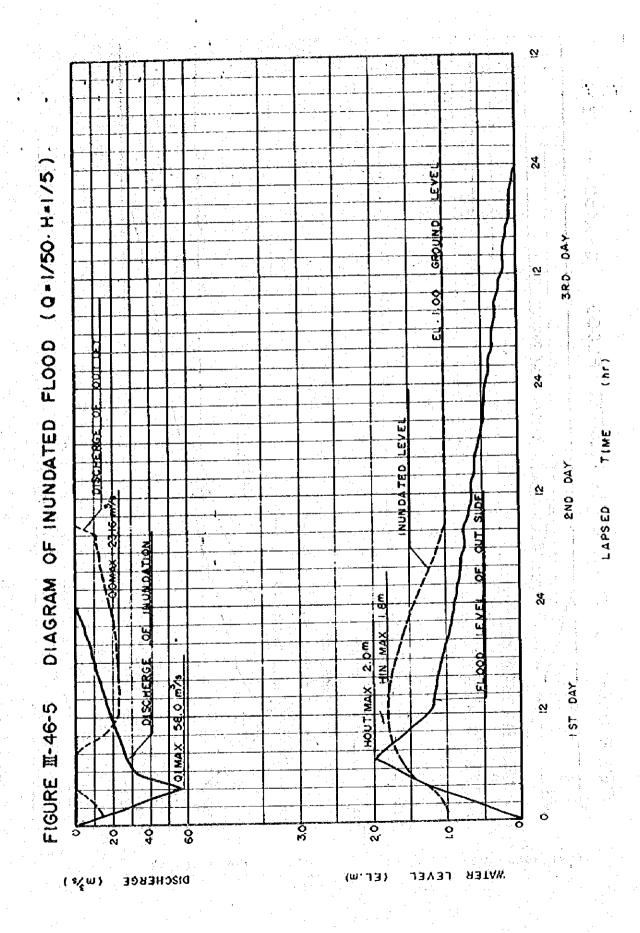

Discharge	Outer Water Level Probability	Max. Inner Water	Ponding Time (hr)	
Probability		Level	1.0 m upper	1.5 m upper
	1/80	EL. 2.08	45 hr	31 hr
1/80	1/20	1.97	37	21
	1/5	1.85	35	20
	1/20	1.92	37	23
1/50	1/5	1.80	32	19
1/20	1/20	1.84	37	21
	1/5	1.74	31	17

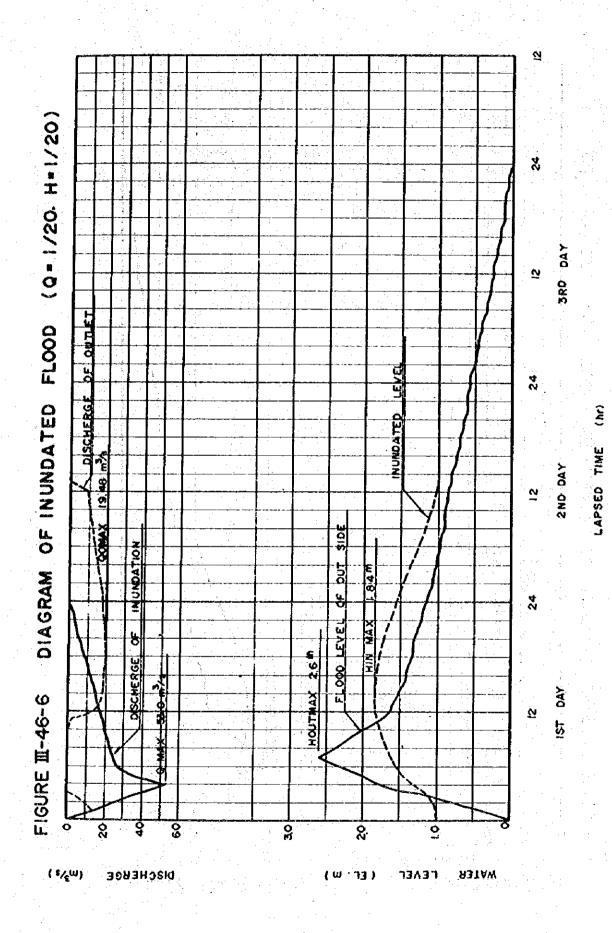

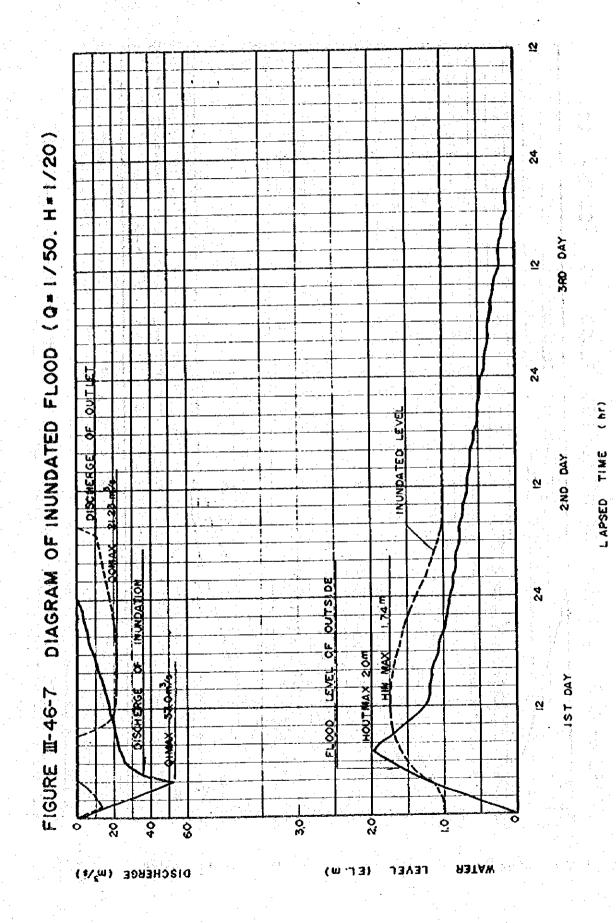

(1) Designed flow

The landside inflow wave form was calculated by the peak flow according to the rational formula. At present, however, there exists a water channel, 25 meter wide and 1.0 meter deep. It is corrected by the H-Q curve of this water channel to review the hydrograph.

In addition, the riverside water level was prepared from the H.Q curve for the same point. Regarding this low water area, the flow from the peak point and the low water point are assumed based on the actual results in 1972.

Among these calculated results, the reaching time for the riverside water was calculated by the formulas of Kraven and Rziha but it is considered that the further review is necessary.

(2) Ponding water depth and time

The ponding water depth and time are as shown in the table above, roughly within 48 hours and are satisfactory even above the ponding depth, more than 1.0m. However, these data should be re-examined again based on the actual measurement data in future although it is depending on the landside inflow hydrologic data.

(3) No.2 and No.3 points

No calculation was made for these points. However, as the drainage areas of both points are smaller than No.1 point and the reaching times are shorter than No.1 point, conditions are on the safety side. Therefore, the

the calculation was omitted and only the drawings will be furnished.

IV CONSTRUCTION PLAN AND IMPLEMENTATION SCHEDULE

4-1 General

(1) Stretch and works

This work schedule has been established to implement river improvement in a stretch of 27 km consisting of a valley (STA. 27 - STA. 23), a sand arresting basin (STA. 23 - STA. 15) and a river channel (STA. 15 - STA. 0). The main work items are presented as follows.

- 1) Preparation works
 - Site office
 - Field office
- 2) Nain works
 - Embankment work
 - Excavation work
 - Revetment work
 - Groyne work
 - Croundsel work
- 3) Additional works
 - Sluice work
 - Retaining wall work

(2) Work time and the number of workdays

The climate in the Philippines can be classified into two pronounced seasons as follows.

- Rainy season from May to November (seven months)
- Dry season from December to April (five months)

As shown in TABLE IV-10, rainfall is hardly experienced in a dry season. The work time shall be scheduled upon various climatic and riparian conditions such as rainfall, existing water level and flow velocity. The stretch for river improvement is characteristic of river-bed water. And surface flow is not observed therein. Therefore, work time in this project can be determined judging from only reinfall condition, because riparian conditions are already agreeable.

From the viewpoint of ease of construction and administration, embankment work included in main works shall be done in a dry season which is advantageous for adjustment of moisture ratio, rolling compaction and transportation of materials.

Since sand and soil excavated from the river-bed will be utilized for embankment materials, excavation work shall be implemented accreding to the embankment work schedule.

Wet masonry and consolidation works included in the revetment work shall be also done in a dry season because concrete work will be attended.

Revetment, gabion cylinder and groyne works are not so subject to rainfall conditions as embankment and concreting works. However, those works are preferable to be done in a dry season, from the viewpoint of disposal of surplus soil and transportation of materials. In conclusion, all main works shall be implemented in a dry season.

The number of workdays in a month in estimated at 25 days/month, excluding four off-days and one day for rain.

(3) Work period and priority

Five-year work period is the most recommendable, taking into account the balance between the estimated volume and facility and/or equipment.

Considering the existing conditions and damages in the past, work process shall be determined so that works in the project area including the valley, sand arresting basin and river channel will be proceeded in the order of priority.

The places emergent to be improved are presented in the order of priority as follows.

i) Sand arresting basin (STA.24 - STA. 21+800)

In this stretch, the most problematic area, flow during a flood goes down out of the river channel. The channel shall be excavated immediately to improve its stability.

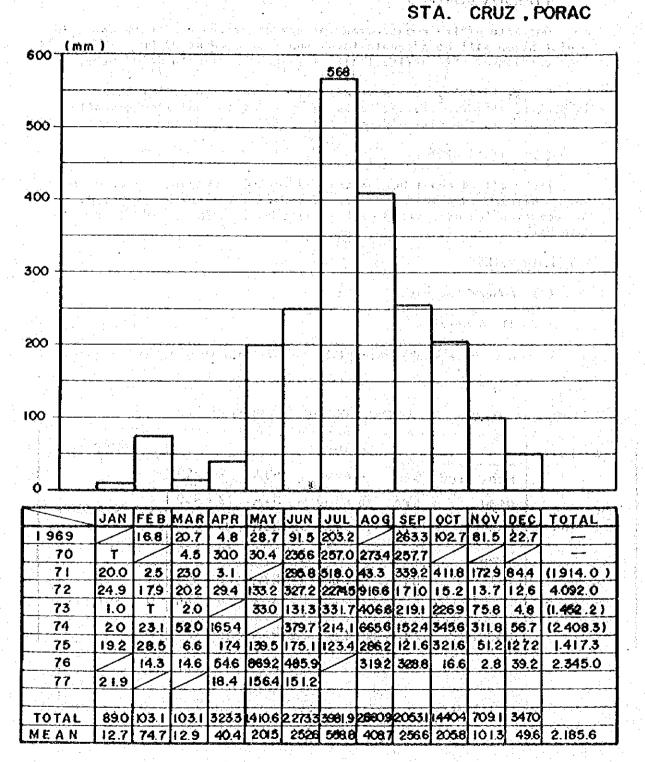

ii) Sand arresting basin (STA.18+700 - STA.18+100)

In the sand bar near Sta. 18+400 exist dozens of houses. Ring levee around the community shall be constructed to protect the inhabitation from flood damages.

111) River channel (STA.16 - STA. 0)

First of all, excavation and embankment works shall be done in the water channel with a low flow capacity. Subsequently the concave side of a river bent and the levee partly damaged by landside water shall be improved and the whole river channel in this stretch shall be completed.

TABLE - III - 21 MEAN RAINFALL OF EACH MONTH

4-2 Preparative Work

Preparative work consists of site office construction and field office construction.

(1) Site office

One site office constructed for the convenience of work administration will be adequate for a short stretch of 27 km. The construction of site office shall be launched prior to main works.

In the vicinity of a site office, concrete and soil testing laboratry, factory, storage-house and parking lot shall be installed in addition to the site office.

(2) Field office

Field office shall be constructed to stock temporarily utensils and materials, in which space for clerical work shall be prepared. The construction of a field office shall be done in accordance of Main Works.

4-3 Hain Works

(1) Embankment work

i) General

Places to be embanked are given in the following table.

TABLE III-22 LOCATION OF EMBANKMENT

Works		Location		Quantity
	Left, Right,	STA. 0 + 50 ~	STA. 2 + 500	
New	Right,	STA. 13 + 500 ~		V = 443,073 m ³
Embankment	Left,	STA. 14 + 500 -	STA. 23	
	Right,	STA. 22 + 100 -	STA. 23 + 500	
	Left,	STA. 2 + 500 -	STA. 6 + 550	
Widening	Right,	STA. 2 + 500 ~	STA. 7 + 700	v = 197,977
	Right,	STA. 10 + 950 ~	STA. 16	

In principle, sand and soil excavated from a river-bed shall be used as embankment materials. However, river-bed materials are sandy soil with a low viscosity of 2 or 3%. In case that it is necessary to arrange soil texture (C and b) and mixture of grain-size, materials with a high viscosity from a borrow pit shall be mixed in embankment materials.

ii) Construction

Materials obtained from river-bed excavation shall be stocked temporarily in a stockyard to adjust moisture ratio.

Bulldozer (21 t) for land grading and dozershovel (1.2 m³) for loading shall be prepared in the stockyard.

Embankment materials shall be conveyed from the stockyard to the embankment site by a dump truck (8.0 t).

Construction method at the site can be classified into the following two cases.

FIGURE-III-47 |

NEW EMBANKMENT

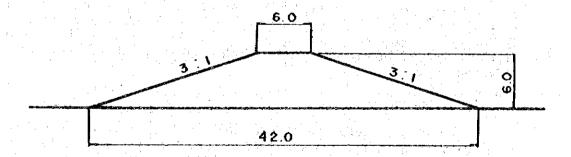

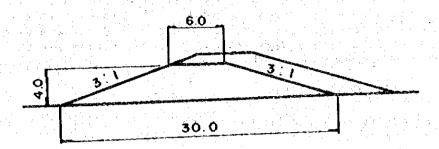

FIGURE-III-48 \ LEVEE WIDENING

As to the new embankment, the materials shall be directly dumped on the filling ground by a dump struck.

After surface grading by a bulldozer, rolling compaction shall be done by an automatic vibration roller (6t).

As to the levee widening, it will get difficult for a dump struck to access to the filling ground in the proportion of the height of a filling ground because of a narrow filling ground. Therefore, materials shall be filled up temperarily in the vicinity of the filling ground by a dozer shavel (1.2 m³). After surface grading by man power, rolling compaction shall be done with a handy vibration roller, and in addition a soil compactor shall be prepared. The bench cut work of the existing levees shall be implemented prior to the levee widening work.

(2) Excavation

Excavation includes low-water channel excavation which commands a majority in quantity and excavation for river bed protection work, both of which will be executed to excavate gravels. Mechanic schedule shall be divided into two types; namely, excavation-on-land and excavation-in-water on the ground that in a dry season underground water level is so high due to underflow water though surface runoff is scarecely found in the existing river channel.

i) Excavation-on-land

Excavation-on-land will be applicable to the case that water depth is less than 50 cm. A Bulldozer (21t) shall be operated for excavation and compaction. Loading shall be done by a dozer shovel (1.2 m³). And sand and soil loaded by a dozer shovel shall be conveyed to the stockyard as embankment materials by a dump truck (6t).

(i) Excavation-in-water

According to the soil data B.H.1-7 and 1-8, underground water reaches up to 1.0 - 1.5 m under the ground. The stretch to which excavation-in-water will be applied covers the sand arresting basin (Sta.20+400 - Sta.20+850) and the confluence with Gua-gua River. Excavation and loading shall be done by a backhoe (1.2 m³). A bull-dozer (21t) shall be also prepared in the site. Sand and soil excavated shall be conveyed to the stockyard by the same way as excavation-on-land.

(3) Revetment work

Revetment work consists of the following two types:

- Wet masonry (high-water channel revetment in the total length)
- Gabion cylinder (low-water channel revetment at the concave side of a bent and landside revetment)

i) Wet masonry

In order to protect the slope surface from gully erosion, wet masonry work shall be done according to the schedule of embankment work.

Cobble stones for wet masonry purchased in a market shall be temporarily deposited in the vicinity of the site. Conveyance and setting shall be executed by man-power.

Concrete for wet masonry and foot protection shall be mixed by a portable mixer (0.2 cu.m./batch). Piles with a length of 2.5 m for foot protection shall be driven by man-power.

1i) Gabion cylinder

Gabion cylinder in \$45 shall be used. Wire (#8) wearing and cobble stone setting shall be prepared by man-power. Steel wires shall be produced at a factory in the site office. Boulder shall be set at the site.

Brushwood shall be set at the bottom of gabion cylinder to prevent drawing-out of sand.

(4) Groyne work

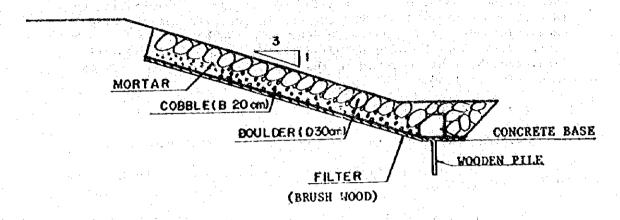

The following shows two types of the groyne work.

Skeleton Works (Vally Section)

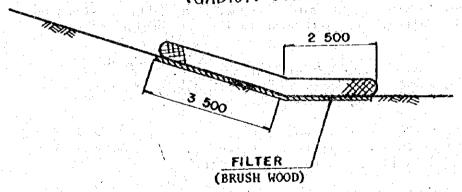

Pile Levee (Sand Arresting Basin)

FIGURE III-49' TYPE OF REVENMENT

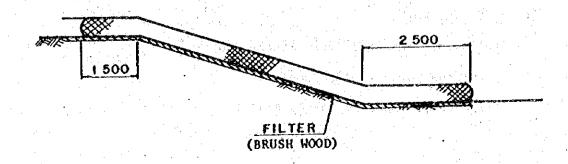

WET MASONRY

LAND SIDE RERVIMENT (GABION CYLINDED)

LOW WATER REVETMENT (GABIEN CYLINDER)

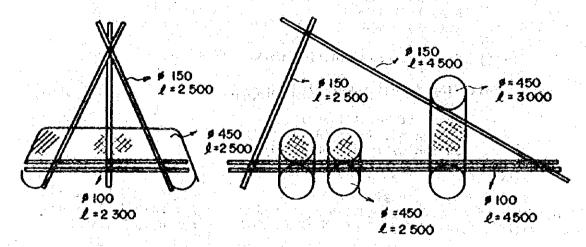

1) Skeleton works (Groyne Type A)

Fabrication of skeleton and setting of Boulder are to be carried out by manual labor at the construction site.

FIGURE II-50

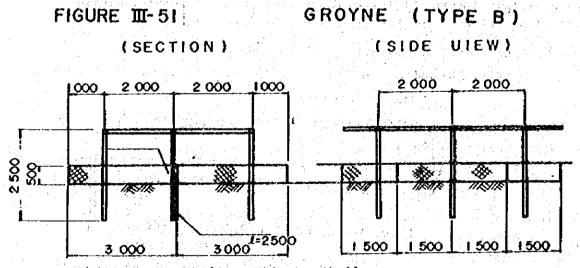

GROYNE (TYPE A)

2) Pile groyne(Groyne Type B)

Gabion mat, length 3.0m x width 1.5m x thickness 0.5m, is the foundation of pile groyne. Since the length of piles are only 2.5 m, they are driven by manual labor.

In fabrication of gabion mats, just like gabion cylinders, wire mats are made in factories, and setting of Boulder and sharpening of piles are carried out at the construction site.

(5) Ground-sel (Consolidation Work)

Type and location of the consolidation works are as shown below.

Concrete Consolidation Works (Location: 2)

STA. 19 + 600

STA. 20 + 900

Wet Mortar Masonry Consolidation Works (Location: 7)

STA. 26 + 400

STA. 25 + 700

STA. 19 + 300

STA. 18 + 300 (Location: 2)

STA. 16 + 150

STA. 15 + 900

1) Concrete consolidation works

The following is major work items.

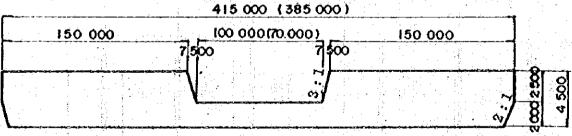

Concrete Works (Body)
Gabion Mat Works (River-bed)
Gabion Cylinder Works (Wing)
River-bed Excavation

Since details are given elsewhere in the foregoing with regard to execution of works of gabion mats, gabion cylinders and river-bed excavation, only execution of concrete works is taken up herein.

According to the field reconnaissance, no surface water was observed in dry months, so diversion works are not considered necessary. Upon completion of river-bed excavation works, concrete placement works will take place.

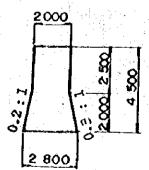

Aggregate for concrete will be purchased. Mixing will be done by means of mixers, capacity 0.2 cu.m/batch each. Transportation of concrete will be manual. Concrete placement will be started first at opening taking drainage into consideration, and for portions below ground-water level, underwater concreting is designated because of anticipated difficulties in dewatering from the results obtained from the soil tests of the river-bed materials.

FIGURE III-52 Concrete Consolidation Works Standard Dmensions
(Ground-sel Type B)

Note: Inside bracket; upstream end of sand arresting basin

Outside bracket; downstream end of sand arresting basin

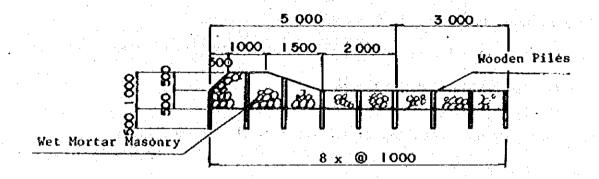

2) Wet moratar masonry consolidation works

The following is major work items.

Grading Works
Piling Works
Hurdle Frame Works
Boulder Setting Works
Mortar Works

FIGURE II-53

GROUNDSEL (TYPE A)

Construction procedure

The following is a description of the construction procedure in the order of work sequence.

(1) River-bed excavation and grading

Land excavation, 0.5 meter in depth, and grading are carried out by 21-ton bulldozers, and loading and hauling are carried out by 1.2-cu.m. shovel-dozer and 8-ton dump trucks.

(2) Piling works

Piles come in two sizes, one is 1.0 m in length and 150 mm dia., and the other 1.5 m and 150 mm. Penetration is only 0.5 m, and this makes manual drive of the piles practical. Piles are sharpened on the job site.

(3) Hurdle frame works

Hurdle frame works mean either fitting of cross beam logs on the boulder with mortar, or split bamboo coverings on the boulder. In either case, the work is to be executed by manual labor after the main piles are driven home.

(4) Boulder setting

After completion of hurdle frame works, set boulder in the framework, from the temporary storage near the construction site, by manual labor by the aid of straw baskets.

(5) Motar works

In the boulder with mortar portion, in parallel with the boulder setting mortar is also placed at a list of 0.5 meter. Mortar is mixed by a portable mixer, capacity 0.2 cu.m. For transportation; wheelbarrows are used.

4-4 Additional Work

Kinds and location of the additional works are shown below.

Drainage Sluice (Location: 3)

STA. 1 + 856

 $2.0m \times 2.0m$ Box Culverts, 2-pc., L = 32.0m

STA: 1 + 900

2.0m x 2.0m Box Culverts, 3-pc., L = 32.0m

STA. 7 + 470

1,650mm I.D. Hume Pipe, L = 9.720m

Retaining Wall

Mancation Bridge, direct downstream area Extension: L = 320m

(i) Drainage Śluice

Sluice shall be embeded prior to construction work of levee. The following is description of the work procedure in sequential order.

1) Excavation and grading

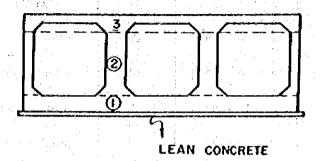

A 21-ton bulldozer will be used for excavation and grading. Surplus soil from excavation will be loaded onto 8-ton dump trucks by 1.2 cu.m. shovel-dozers. The dump truck will haul the excavated soil to the stock yard.

2) Concrete Pile Driving (0.4m x 0.4m x 24.0m)

For pile driving, a diesel pile hammar with 2-ton raw will be used. Since the length of the pile is long, L=24.0~m., piles will be spliced.

3) Concrete work

Since concrete mixing is carried out by a 0.2 cu.m/batch mixer, concrete will be placed on top of the lean concrete layer, in three stages, marked (1), (2) and (3) as shown in the section drawing below.

4) Embankment of levee

After concrete placement and curing, embankment of the levee will follow.

With regard to the embankment of the levee, exactly the same procedure as detailed in "Embankment" will be followed. To prevent leakage, all the adjoining portions of the sluice and levee shall be filled up with clayey soil.

5) Fitting revetment works

After completion of sluice embedment, the fitting revetment of the inlet and outlet will be carried out.

(ii) Retaining wall work

Retaining walls are constructed near the bottlenecked left and right branches of the "Y" bifurcation of the Pasig-Potrero River where two bridges on the Porac-Angeles Highway are spanning near the village of Mancation. In mixing concrete, a portable mixer, 0.2 cu.m./batch, will be used, and the placement will be carried out with a lift of 1.0 meter each.

4-5 List of construction machine

TABLE III-23 LIST OF MAIN MACHINE

name of machine	specification	number	remark

4.8. Cost Estimate

1. Project Cost

The project cost is estimated in the following terms:

- i) Unit costs in May of 1978 are regarded as a criterion for the estimation.
- ii) Costs for machines, steel products and engineering services are included in the foreign currency portion. Other materials and labour are prepared in the local currency.
- iii) Construction works for this project are done by the local contractor in accordance with the contract.
- iv) Physical contingency is equivalent to 15% of the total construction cost excluding engineering cost, and price contingency is not included in the cost estimate.
- v) Cost for engineering services is equivalent to 12% of the total construction cost.
- vi) The exchange rate in conversion from Peso to US Dollar is P7.4 = US\$1.00.

Details of the cost estimate and annual construction costs are given in TABLE III-26-1 and TABLE III-26-2 respectively.

2. Operation and Maintenance Cost

Costs for operation and maintenance in the construction period include; (1) five thousand pesos (P5,000) for cross and profile leveling and water stage observation, (2) seventy thousand pesos (P70,000) for operation and maintenance of river structures, (3) fifteen thousand pesos (P15,000) for excavation (30,000 m³/yr.) in a stretch of 3 km from Bacolor to the estuary.

After the completion of works, annual operation and maintenance cost is estimated to be one hundred and ninety-five thousand (P195,000) for the above-mentioned costs (1), (2) and (3) and excavation (274,000 m³/yr.) in the sand arresting basin in the upstream of Mancatian bridge.

Details of operation and maintenance costs are given in TABLE 111-27.

3. Economic Cost

Economic cost is estimated to be the foreign currency in the Project Cost excluding tax. Tax levied on articles is mentioned below.

a) Steel Bar and Steel Pipe

50%

b) Construction Machines

40%

Details of economic cost are presented in TABLE III-28-1, III-28-2.

SURVEY

I. SURVEY

This report summarizes the results of surveying made from December 12, 1977 to March 31, 1978 for the Pasig-Potrero Plood Control and Sabo Project in cooperation with the local counterparts.

Survey work required for sabo and river improvement plan had been made on the following items.

- 1. Setting of datum point (setting of distance-mark)
- 2. Longitudinal survey (38,176 m)
- 3. Cross-sectional survey (39,810 m)
- 4. Detail survey in the vicinity of the important structure site (217,040 m²)
- 5. Zero elevation survey

1. Setting of Datum Point

A starting point, (STA.) 0+000 m is set at the confluence of the Gua-Gua River and the Pasig-Potrero River. Distance marks are set up every 200 m along the tops of both side levees or on the rigid ground near the riparian. And concrete distance-marks are set every 1 km.

Prior to measurement of elevation, B.M. PARC 6 (Cabetican, Bocolor) with an elevation of 4.414 m and B.M. PA.No.41 (Gua-Gua) with an elevation of 2.388 m were assured. In this survey, PARC 5 is considered as a starting point 0.000 m and measurement of elevation was made toward the up-streams of the Pasig-Potrero, Timbu and Yangca Rivers. Elevation of each B.M. is given in TABLE I-1.

To check accuracy of the survey data, elevation of the Mancatian Bridge is measured from both B.M. PARC 29 (Porac Bridge located in Porac) and PARC 6 (the starting point).

2. Longitudinal Survey

To prepare a longitudinal section, elevation of distance marks on the both-side levees, ground level, levee top elevation and the height of the existing structures were measured.

3. Cross-sectional Survey

To prepare a cross-section, elevation of the hydrometric section was measured based on the distance-mark. Cross-sectional survey was made at a pitch of 1 km between 0+000 m and the top point in the fan-made of the Pasig-Potrero River, 400 m and/or 600 m between the fan-head and the confluence with the Timbu River, and 200 m in the up-stream of the confluence with the Timbu River and in the Timbu River and the Yangca River.

4. Detail Survey

Plane survey was carried out in the vicinity of No. 5 Dam and from No. 5 Dam to the water-fall at the estuary of the Timbu River to prepare maps with a scale of 1/300 and 1/500 respectively.

Detail survey was also carried out at the following riparian structure sites to prepare a map with a scale of 1/200.

- The right and left levees in the vicinity of 1+800 m (2 places)
- The upstream right levee in the vicinity of 13+250 m
- The upstream left levee in the vicinity of 13+200 m

5. Other Survey

Cross-sectional and zero-elevation survey were made as follows:

- i) Cross-sectional survey at the confluence of the Pasig-Potrero River and the Gua-Gua River.
- ii) Cross-sectional survey at the graduated staff gauge places along the Pasig-Potrero River, Gua-Gua River and Porac River.
- iii) Zero-elevation Survey at the graduated staff gauges located at Haciende Dolores, Mancatian Bridge, Bacolor, Gua-Gua and Minalin Gauge.
