

### 3.6 Irrigation Benefit

Irrigation benefit to be expected is defined as the difference of primary profit from crops between future with project and without project conditions. On the basis of the estimated production cost and gross income, primary profit for crop per ha is calculated both on future with and without project conditions as follows, and details are as shown in Table 3.5 to 3.10.

	With Project			Without Project		
	Gross Income	Pro-duction Cost	Primary Profit	Gross Income	Pro-duction Cost	Primary Profit
1) Paddy						
Irrigated (wet)	8,415	3,206	5,209	4,413	2,422	1,991
Irrigated (dry)	9,350	3,334	6,016	4,899	2,534	2,365
Rainfed (wet)	-	-	-	3,871	2,273	1,598
2) Mongo beans	1,840	1,097	743	1,840	1,097	743

Applying the primary profit per crop estimated above to crop area, total primary profits accrued from agricultural production for the irrigation project are estimated both on without and with project conditions. Based on this result, irrigation benefit is calculated. The benefit will be expected to increase linearly year by year and reach the full benefit in and after five years after the completion of the project. The irrigation benefit at the full stage is estimated at about 98 million pesos for the diversion dam scheme and about 76 million pesos for the pump scheme, respectively, as shown in Table 3.11.

### 3.7 Farm Economy

In order to assess the irrigation project from farmers' economy view point, analyses of farm budget for typical farmer are examined under both the future without project and the future with project conditions.

After the implementation of the irrigation project, year round irrigation will permit double cropping of paddy per annum for the most of the project area and increasing unit yield of paddy to 5 tons per ha for dry season paddy and 4.5 tons per ha for wet season paddy, respectively. As a result, drastic increase on farm income in the future with project condition can be expected in the typical farmer. On the other hand, substantial increase on farm income will be expected in the future without project condition. The typical farm budgets in both future without and with conditions are prepared as shown in Tables 3.12 and 3.13 and outlined below.

a) Without Project Condition

(Unit: ₱1,000)

Item	Single Crop of Paddy (Rainfed)	Single Crop of Paddy (Irrigated)	Double Crop of Paddy (Irrigated)
I) Gross Income	14.3	14.8	19.4
(1) Farm income	5.3	5.9	11.3
(2) Off-farm income	9.0	8.9	8.1
II) Gross Outgo	14.0	14.6	18.9
(3) Production cost	3.6	4.1	8.5
(4) Living expenses	10.4	10.4	10.4
III) Net Reserve (Capacity to pay)	0.3	0.2	0.5
IV) Net Farm Income (1-3)	1.7	1.7	2.8

b) With Project Condition

(Unit: ₱1,000)

Item	Diversión Dam Scheme	Pump Scheme
I) Gross Income	29.9	26.5
(1) Farm income	21.2	17.8
(2) Off-farm income	8.7	8.7
II) Gross Outgo	26.5	24.3
(3) Production cost	13.0	10.8
(4) Living expenses	13.5	13.5
III) Net Reserve (Capacity to pay)	3.4	2.2
IV) Net Farm Income (1-3)	8.2	7.0

Farm incomes with project on the typical farm under single cropping of paddy will be expected to become about 3 and 4 times of that of without project condition for the Pump and the Diversión Dam Schemes, respectively and about 2 times on the typical farm under double cropping of paddy.

Net farm incomes with project on the typical farm on single cropping of paddy will be expected to increase 4 to 5 times and about 3 times on the typical farm under double cropping of paddy.

Annual net reserve or capacity to pay will be about ₱250 on single cropping farm and ₱500 on double cropping of paddy farm in without project condition and become ₱3,400 in the Diversion Dam Scheme and ₱2,200 in the Pump Scheme.

The increased net reserve will offer incentives to the farmers and substantial capacity to pay will enable them to pay irrigation fee.

From the productivities of land and labor, it is expected that the both Diversion Dam and Pump Schemes will highly improve such productivities as follows:

	Productivity of Labor (₱/man-day)	Productivity of Land (₱/ha)
With Project		
- Diversion Dam Scheme <sup>/1</sup>	42	5,142
- Pump Scheme <sup>/2</sup>	41	4,329
Without Project <sup>/3</sup>	18	1,044

/1: Productivity of labor: ₱7,713/185 man-days = ₱42/man-day  
Productivity of land : ₱7,713/1.5 ha = ₱5,142/ha

/2: Productivity of labor: ₱6,494/157 man-days = ₱41/man-day  
Productivity of land : ₱6,494/1.5 ha = ₱4,329/ha

/3: Productivity of labor: ₱1,566/89 man-days = ₱18/man-day  
Productivity of land : ₱1,566/1.5 ha = ₱1,044/ha

3) Paddy Only (Irrigated) - 2,900 ha	31	44	21	-	-	-	-	-	34	60	50	24	264
4) Paddy/Paddy (Irrigated) - 2,300 ha	39	19	25	35	26	41	49	22	13	36	62	47	414
C) Balance (A-B)	263	264	286	301	310	234	182	196	239	175	141	191	2,782

<sup>/1</sup>: (Labor force from farmers + Labor force from landless workers) x Yearly workable days = (5,900 + 7,900) x (365 days x 80%) = 4,030,000 man-days/year

Labor force from landless workers in the irrigation development area is estimated as follows:

$$L_f = Th \times Lw \times Fs \times Ra \times Ar = 16,390 \times 0.26 \times 6.4 \times 0.58 \times 0.5 = 7,900 \text{ persons}$$

Where, Lf: Labor force from landless workers

Th: Total households (16,390)

Lw: Percentage of landless workers household to total household (26%)

Fs: Family size (6.4 person/household)

Ra: Ratio of age distribution between 15 and 59 (58%)

Ar: Ratio of available labor force (50%)

Table 2.30 SURVEY ITEMS OF QUESTIONNAIRE  
FOR FARM ECONOMIC SURVEY

- 
1. Family Size
  2. Farm Size
  3. Tenurial Status
  4. Cropping Pattern and Farming Practices
    - 1) Cropping pattern
    - 2) Farming practices and inputs requirement
      - Seed
      - Fertilizer
      - Agro-chemicals
      - Labor requirement
      - Animal power and machinery requirement
  5. Production and Disposition of Products
  6. Livestock Inventory
  7. Inventory of Farm Machinery and Equipment
  8. Market and Farmgate Prices
  9. Gross Income
    - 1) Farm income
    - 2) Off-farm income
  10. Production Cost
    - 1) Farm inputs
    - 2) Irrigation fee
    - 3) Land rent and amortizing fee
    - 4) Labour cost
    - 5) Animal power and machinery
  11. Living Expenses
    - 1) Food consumption
      - Rice
      - Other food
    - 2) Living expenses except food
  12. Farmer's Intension
-

[1]: The area is composed of 10,100 ha of paddy field and 1,000 ha of swamp/grassland. Swamp/grassland is not utilizable for agricultural production.

Note: Based on the estimation of future land use mentioned in section 3.2, planted area without project by season is estimated as follows:

Item	Present Condition		Without Project	
	(Unit: ha)		(Unit: ha)	
<u>Irrigated Field</u>				
1) Single crop area - wet season	9,200	8,100		
- dry season	4,000	3,500		
2) Double crop area	2,900	2,600		
(wet season)	2,300	2,000		
(dry season)	(2,300)	(2,000)		
<u>Rainfed Field</u>				
- wet season	2,300	2,000		

Table 3.12(1) TYPICAL FARM BUDGET WITHOUT PROJECT  
(FARM SIZE 1.5 HA)

(1) Single Crop of Paddy in Rainfed Land - Lessee

Item	Area (ha)	Unit Yield (t/ha)	Production (t)	Unit Price (P/t)	Amount (P)
I) <u>Gross Income</u>					<u>14,280</u>
1) Farm Income					5,287
- Wet season paddy	1.50	2.07	3.11	1,455	4,525
- Diversified crop	0.15	0.40	0.06	4,600	276

## APPENDIX VI IRRIGATION AND DRAINAGE

### CHAPTER 1 EXISTING IRRIGATION AND DRAINAGE SYSTEM

#### 1.1 Existing Irrigation System

##### 1.1.1 General

The irrigation systems in the Philippines are classified into the following four categories: a) National Irrigation System, b) Communal Irrigation System (CIS), c) Pump Irrigation System (PIS), and d) Private and other irrigation system.

In the Project area for the irrigation development, there are no existing national irrigation systems but a few communal irrigation systems and many pump irrigation systems covering about 3,930 ha of paddy fields or approximately 36% of the area to be served by the Project.

##### 1.1.2 Communal Irrigation System

The water sources of communal irrigation system (CIS) are usually dependant on the discharge of small rivers and streams. CIS is operated by gravity with diversion dam and canal systems commanding generally less than 100 ha of field. CIS has been constructed by NIA on provincial basis and operation and maintenance are conducted by irrigators association with guidance of Farm Systems Development Corporation (FSDC) and NIA.

In the irrigation development area, the following five CIS exist.

<u>Name of CIS</u>	<u>Source of Water</u>	<u>Service Area (ha)</u>	
		<u>Wet Season</u>	<u>Dry Season</u>
San Juan Baño	Baño Creek	365	130
Gatiawin	Buracan Creek	129	10
Lacmit	Lacmit Creek	405	80
Inumang Baca	Inuman Baca Creek	115	0
San Isidro	Inuman Baca Creek	60	0
Total		<u>1,074</u>	<u>220</u>

Only 9.8% and 2.0% of the irrigation development area are irrigated by CIS during wet and dry season respectively. The service area of the above CIS is shown on Fig. 1.1.

### 1.1.3 Pump Irrigation System

Pump irrigation has been developed to increase the irrigable area by NIA and FSDC. In the irrigation development area of the Project, many pump irrigation systems exist. The potential service area of those PIS is reported at about 2,860 ha or 26% of the development area by 107 systems and 214 systems of surface water pump and ground water pump respectively as shown in Table 1.1 in detail. Major pump stations in the development area are shown on Fig. 1.1. Those potential service areas, however, are not always irrigated mainly due to high cost required for operation and maintenance especially fuel and sometimes due to sea-water intrusion during dry season in the lower area.

### 1.1.4 Private and Other Irrigation System

In addition to the above mentioned irrigation systems, there are some private and other irrigation systems constructed and operated by private personnel or association such as Mother Milaros Foundation and Philippine Business for Special Progress without any financial assistance from the Government agencies. The number of the private irrigation systems and their service area are not clarified in the irrigation development area.

### 1.1.5 Water Right

For making use of the existing river discharge, the discharge corresponding to the water right authorized in the downstream is to be assured always.

The existing water rights in the Pampanga River authorized by National Water Resource Council (NWRC) in the downstream of Arayat are 10 places amounting 2.8 m<sup>3</sup>/s in all as shown in Table 1.2. The purpose of water use of these water rights are all for irrigation. However, since 4 places amounting 1.46 m<sup>3</sup>/s of water rights are to be integrated to the Project, the remaining water rights, 6 places and 1.34 m<sup>3</sup>/s, are to be considered for the Project planning.

## 1.2 Present Drainage Condition

The irrigation development area of the Project is protected from the flood of the Pampanga River by the existing set back levee. While, there is no direct drainage outlet from the area to the Pampanga River since the water surface elevation during flood in the River is higher than the ground elevation in the area. Accordingly, all drainage courses flow into the Guagua River Basin. No drainage facilities but natural drainage courses are available in the development area at present.

Discharge capacities of major drainage courses such as, the Pau River and the Masalusa River are not adequate since discharges of these major drainage course are rather big due to inflow from the outside of the development area. In accordance with the survey results the discharge capacity of the Pau River and the Masalusa River at their narrowest sections is only 15 m<sup>3</sup>/sec and 10 m<sup>3</sup>/sec respectively. The inadequate drainage capacity as well as lack of drainage ditches in the field courses not only inundation of wide area more than 2,000 ha but also low productivity of paddy and crop damages during wet season.

Accordingly, the drainage plan for the whole development area is essential so as to make the agricultural development plan with year round irrigation.

### 1.3 Water Management of Existing Facilities

#### 1.3.1 Water Management System for CIS and PIS

The construction of CIS and PIS facilities is commenced after the irrigators association is organized by the benefited farmers with assistance of FSDC and an agreement for the amortization of the construction cost in installment in maximum 50 years without interest is made between the association and NIA or FSDC. After the completing the construction, operation and maintenance of facilities and the collection of amortization area conducted by the association for which a technical assistance is provided by NIA and FSDC.

Operation and maintenance for private or other system are conducted by private personal or associations obtaining a technical assistance from NIA and FSDC.

#### 1.3.2 Water Management System for National Irrigation System

Although there is no national irrigation system existing in the irrigation development area, water management system for national irrigation system is explained hereinafter for reference.

The construction of the National Irrigation System is directly managed by NIA. After completion of the construction of the National Irrigation System, operation and maintenance of the system are conducted by NIA from the reservoir dam and/or the diversion dam to turnout on lateral and sublateral canals. Operation and maintenance of field ditch after turnout are conducted by irrigators association organized on every turnout and field ditch assisted by management technician or irrigation technician.

The irrigation fee is collected from benefited farmers for payment of operation and maintenance cost of the system. The irrigation fee charged to the farmers is 2.0 to 2.5 cavans or ₱130 to 162.5 per hectare for wet season and 3 to 3.5 cavans or ₱195 to 227.5 per hectare for dry season.

In UPRP including PRIS, AMRIS and TISIP, irrigation management technologist and technician are assigned for every 2,500 ha and 500 ha respectively, so that water management of the irrigation system is to be properly conducted and the limited irrigation water is to be efficiently utilized. The water management technician who is to be a graduate of agricultural college is assigned in the field after completing one year training course.

#### 1.4 Existing Development Plan

##### 1.4.1 Irrigation System

There is no existing irrigation development plan of CIS and PIS in the irrigation development area of the Project except some rehabilitation of PIS under FSDC.

##### 1.4.2 Drainage System

In the development area, there are a few plans for improving the Matubig River under MPWH. These plans, however, aim to improve the drainage conditions mainly in towns and residential areas and the improvements are not entire river course but only place to place. Since the design criteria of the improvement is not clear, the drainage plan of the Project shall be made separately.

## CHAPTER 2 IRRIGATION AND DRAINAGE DEVELOPMENT PLAN

### 2.1 General

The previous study in the Second Interim Report concluded that the objective area for the agriculture and irrigation development is lying south of Mt. Arayat and west of the Pampanga River in Pampanga Province and the water source of the irrigation is the discharge of the Pampanga River at Arayat in lieu of the San Antonio Reservoir. Further, the present discharge of the River is only considered as the water source for the irrigation development plan not taking return flows into account since these return flows be not expected soon until the irrigation projects with reservoir proposed in the upstream of Mt. Arayat shall be completed.

For the drainage plan, the drainage facilities from on-farm level is made to improve present worse drainage condition of the area. The main drainage courses in the plan are of the enlarged existing rivers flowing from the development area to the Guagua River because the water surface elevation of the Pampanga River during the design flood is being higher than the ground elevation in the development area for one week or more.

### 2.2 Irrigation Development Area

Demarcation of the irrigation development area is basically determined by taking the aspects to be discussed hereinafter into consideration.

#### (1) Intake Water Surface Elevation

The intake water surface elevation shall not be higher than EL. 8.50 m for the diversion dam scheme and for the pump scheme as discussed in Chapter 3 in detail.

#### (2) Soil Condition and Land Use

As discussed in the Appendix I and V, soils in the project area are clay and clay loam for the area of which ground elevation is lower than EL. 10 m and sandy loam for the area of which ground elevation is between EL. 10 m to 40 m. These soils are suitable for paddy cultivation. Sandy loam, however, requires more irrigation water since the percolation is more than 3 mm/day while the percolation of clay and clay loam is limited at 2 mm/day or less.

Major crops of the project area are mainly paddy in lower area and sugarcane in higher area. Taking the project goal and the land tenure system of sugar land into consideration, it is advisable to give a priority of the development to paddy land.

### (3) Topographic Condition

In demarcation of boundary of the southern part of the irrigation service area, land with lower than about EL. 1.5 m is excluded from the service area. As such the land has extremely flatness with considerable microrelief higher head of irrigation water is required to irrigate the land. Further many small rivers and creeks are developed in the land. Implementation of irrigation water supply systems to the land therefore will require huge amount of construction cost, which indicates that irrigation development for the land on a large scale is not economically feasible.

Accordingly, the irrigation development area is demarcated at 14,000 ha with 11,000 ha of the irrigation service area as illustrated on Fig. 2.1. Ground elevation of the irrigation service area varies between about EL. 1.5 m to 8.0 m.

## 2.3 Water Source

### 2.3.1 General

The water source for the irrigation development is the discharge of the Pampanga River at Arayat. Average annual mean discharge for 14 years from 1965 to 1978 to Arayat is 250 m<sup>3</sup>/s. Since the seasonal fluctuation of the river discharge is very big, the irrigation development plan is examined based on 10 day mean discharge corresponding to the water requirement calculation. 10-day mean discharges at Arayat for 14 years are shown in Table 2.1.

In the irrigation development area there are creeks and rivers on which a few communal irrigation systems are operated at present. However, since the discharges of these creeks and rivers are very small during dry season, these discharges are neglected for irrigation development plan.

### 2.3.2 Available Discharge of the River

When making use of the river discharge, the minimum discharge released to the downstream is to be determined to maintain the basic functions of river in addition to the discharge to cover the water right existing in the downstream.

#### (1) River Maintenance Flow

At present there is no certain criteria to determine the river maintenance flow in the Philippines except NIA criteria which aims the maximum use of the river discharge. In accordance with NIA criteria, 90% of the river discharge, which is equivalent to the annual minimum monthly mean discharge in 5-year return period, can be used for the irrigation purpose. For making the irrigation development plan of the Project, the river maintenance flow is to

be determined at the annual minimum 10 day mean discharge in 10 year return period. It is estimated at 5.2 m<sup>3</sup>/s by the probability analysis of the data for 14 years from 1965 to 1978.

(2) Water Right

The existing water rights in the downstream of Arayat bridge authorized by NWRC are shown in Table 1.2. All of the water rights are authorized for irrigation purpose. Among those water rights, rights at Sta. Lucia, Cupan and Matao in Arayat, Mandasig in Candaba and Sta. Rita in San Luis located at the right bank of the river will be integrated in the Project because the service area of these water rights are to be covered by the Project. Accordingly, the discharge corresponding to water rights at left bank, 1.34 m<sup>3</sup>/s, is to be secured with the Project. Since the discharge from the remaining drainage area in the downstream of Arayat is about 30% of the discharge at Arayat, the discharge of 1 m<sup>3</sup>/s will be released at Arayat to correspond the water rights in the downstream. The remaining 0.34 m<sup>3</sup>/s will be covered by the discharge from the remaining drainage area.

Accordingly, the minimum discharge of the river to be released to the downstream at Arayat is 6.2 m<sup>3</sup>/s. Further, the available discharge at Arayat for irrigation purpose is the discharge deducting 6.2 m<sup>3</sup>/s from the actual discharge as shown in Table 2.2.

2.4 Irrigation Method

One irrigation block is assumed as 50 ha of area. The rotational irrigation is applied within this irrigation block. Daily irrigation period is considered for 24 hours for both pump and diversion dam schemes because it takes more than 24 hours for irrigation water to reach from pump station or intake to the tail of the service area.

The levee of paddy field is assumed to be 25 cm in height. The distribution of water depth in the field is illustrated as follows:

Detained Depth  
 Water Depth for Irrigation  
 Application and Effective Rainfall  
 Foregoing Irrigation Depth

The irrigation water is applied when the water depth in the field will be less than 50 mm. Effective rainfall of a rain is to be 50 mm or less. When heavy rainfall takes place, 150 mm out of the rainfall depth is to be detained in the field.

## 2.5 Irrigation Water Requirement

### 2.5.1 General

The two different cropping calendars of paddy as shown on Fig. 1.2 in Appendix V are considered for pumping scheme and diversion dam scheme respectively so as to maintain the maximum utilization of the available discharge in the river and the effective volume of the reservoir discussed in Section 2.6. Irrigation water requirement of paddy is estimated by pan method in ten day basis for 11 years from 1968 to 1978.

The water requirement calculation is conducted by electronic computer in accordance with the programme prepared based on the block diagram and the flow chart as shown on Fig. 2.2 and Fig. 2.3. There are three rainfall stations, namely; San Fernando, Apalit and Arayat, available in the development area. The water requirement calculation is conducted for these three stations for the period of which daily rainfall data are available. The weighted average of the requirement of each station is used as the irrigation water requirement of the Project.

#### (1) Evapo-transpiration

Evapo-transpiration of paddy is estimated on the basis of the surface water evaporation from the standard class-A pan and the crop coefficient.

#### (2) Crop Water Requirement

Crop water requirement on daily basis is calculated by adding percolation loss and water requirement for a nursery period and land preparation work to evapotranspiration.

#### (3) Irrigation Water Requirement

Irrigation water requirement is calculated by deducting effective rainfall from the crop water requirement.

#### (4) Diversion Water Requirement

Diversion water requirement is calculated by adding operation and conveyance losses to irrigation water requirement.

## 2.5.2 Estimation of Evapo-transpiration of Paddy

Evapo-transpiration of paddy is estimated in accordance with the following formula on daily basis:

$$ET = KcPE(D)$$

$$PE(D) = PE(M)/t_m$$

where, ET: crop evapo-transpiration (mm)

Kc: crop coefficient

PE(D): daily pan evaporation (mm)

PE(M): monthly pan evaporation (mm)

t<sub>m</sub>: number of days in month

### (1) Pan Evaporation

Pan evaporation data are available in San Miguel, Tarlac (1968-1979), Baliwag, Bulacan (1970-1989) and Cabanatuan City adjacent to the irrigation development area. The average of monthly pan evaporation at San Miguel and Baliwag is used for the study as shown in Table 2.3. Pan evaporation at Baliwag for 1968 and 1969 is estimated from the data at San Miguel by the method of correlation and regression analysis.

### (2) Crop Coefficient (Kc) of Paddy

In the agricultural research station of NIA Region III at Sabang, Baliwag, Bulacan, evaporation and evapo-transpiration of paddy has been observed by NSDB - NIA water management improvement project since 1970. The crop coefficient (Kc) of paddy is determined based on the analysis of the data obtained through the aforesaid project for 15 crops, 6 crops for wet season and 9 crops for dry season, as shown on Fig. 2.4. As the growing period varies depending on varieties of paddy, Kc is determined for the percentage of the total duration from seeding to harvesting for each crop.

The crop coefficient relative to the respective growing stages obtained from the said figure is as follows:

Percentage of Growing Stage	10	20	30	40	50	60	70	80	90	100
Crop Coefficient	0.80	0.83	0.93	1.04	1.12	1.20	1.21	1.15	1.01	0.85

### 2.5.3 Crop Water Requirement

Crop water requirement is estimated as follows:

Evapo-transpiration + deep percolation water  
+ water requirement needed for land preparation and nursery bed

#### (1) Deep Percolation

Water loss due to deep percolation is assumed at 2.0 mm per day for the study depending on the soil texture found as very fine and fine in the development area as discussed in Annex V and NIA standard based on UPRP study.<sup>/1</sup>

#### (2) Land Preparation

The water requirement for land preparation in paddy field is calculated in the following formula:

$$LP = SS + Kc \times (t\ell/tm) PE + t\ell P + SP$$

where, LP: water requirement for land preparation (mm)

SS: water requirement for land soaking (mm)  
140 mm for wet and dry seasons

Kc: coefficient for evaporation from muddy or shallow basin of water, 0.7

tℓ: number of days for land preparation, 25 days

tm: number of days in month

PE: pan evaporation (mm/month)

P: deep percolation loss, 2.0 mm/day

SP: depth of ponding for transplanting, 25 mm

#### (3) Nursery Water Requirement

5% of total paddy field is considered necessary for nursery. Nursery water requirement is same with actual field in principle for land preparation and crop. However, as more losses due to seepage, application and so on are to be considered, 50% more water than actual field is applied for nursery.

#### (4) Crop Water Requirement

Daily crop water requirement is calculated in accordance with the above procedure and field in the computer memory for the period of which daily rainfall data are available.

---

<sup>/1</sup>: Refer the Report of Land Classification and Supporting Studies on UPRP, NIA Dec. 1971.

#### 2.5.4 Irrigation Water Requirement

The irrigation water requirement is estimated by deducting effective rainfall from the crop water requirement on daily basis and summarized for each 10 days.

##### (1) Irrigation Method

Field condition is considered as follows as discussed in Section 2.4:

- Height of levee is at 250 mm above field surface in average.
- Water depth in the field is kept at 50 mm in minimum and 100 mm in maximum, accordingly, in the daily balance calculation, when the water level is lower than 50 mm, the irrigation water will be applied up to 100 mm.

##### (2) Effective Rainfall

- All rainfalls are considered as a potential effective rainfall, however, when the water depth in the field will exceed 100 mm, the excess will be drained and not effective.
- The average annual effective rainfalls are 758 mm and 729 mm for diversion dam scheme and pump scheme respectively.

##### (3) Irrigation Water Requirement

- Irrigation water requirement on 10 day basis is calculated at San Fernando, Apalit, Arayat as shown in Tables 2.4 to 2.9. The irrigation water requirement of the Project, the weighted average at the above stations, is tabulated in Table 2.10 and Table 2.11. Average annual irrigation water requirements for diversion dam scheme and pump scheme are 1,401 mm and 1,424 mm.

#### 2.5.5 Diversion Water Requirement

Diversion water requirement for irrigation is estimated by dividing the irrigation water requirement by the overall irrigation efficiency.

The irrigation efficiencies are assumed as follows for this study:

System Component	Rice	
	Wet Season	Dry Season
Field Application	70	80
Conveyance System	80	80
System Operation	85	85
<u>Overall</u>	<u>48</u>	<u>54</u>
