IV. STABILITY ANALYSIS AGAINST SLIDING FAILURE

Stability Analysis Against Sliding Failure

Stability analysis against sliding failure has been carried out by applying the slice method to the slip circle surface. The safety factor is obtained by the following formula:

$$S.F = \frac{\Sigma\{C \cdot \ell + (N - Ne - U + Np + Wn) \times \tan\phi\}}{\Sigma(T + Te - Tp + Wt)}$$

Where, S.F; safety factor

C; cohesion of materials on slip circle of each slice

ℓ; arc length of slip circle of each slice

N; normal force acting on slip circle of each slice

Ne; normal force of earthquake load acting on slip circle of each slice

U; pore pressure acting on slip circle of each slice

Np; normal force of hydrostatic pressure acting on slip circle of each slice

Wn; normal force of surcharge water acting on slip circle of each slice

ϕ; angle of internal friction of materials on slip circle of each slice

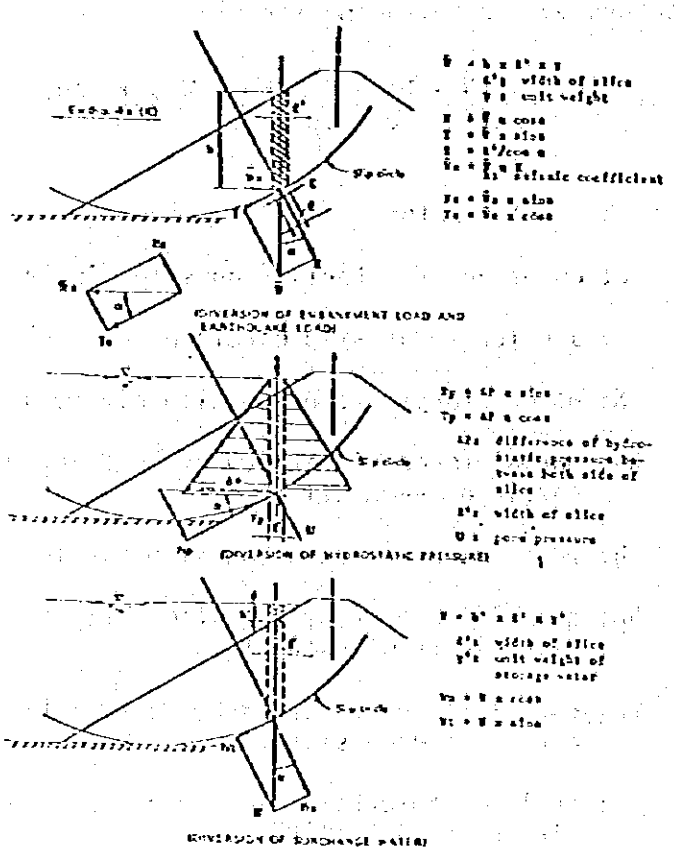
T; tangential force acting on slip circle of each slice

Te; tangential force of earthquake load acting on slip circle of each slice

Tp; tangential force of hydrostatic pressure acting on slip circle of each slice

Wt; tangential force of surcharge water acting on slip circle of each slice

Division of acting loads to the normal and tangential forces is shown in the following figure.



Stability Analysis with Slip Circle Method

Allowable minimum safety factor is decided in conformity with the Design Criteria For Dams authorized by Japanese Government, that is to say, it must not be less than 1.2 in any case. The repeated computation should be made by using the above equation to gain the minimum value of the safety factor for a variety of sliding surfaces. The computation procedures, the so-called trial-and-error, can be advantageously carried out by computer operation according to the flow chart shown below.
