INTERNATIONAL COOPERATION

PREFACE

In response to the request of the Government of the Republic of Indonesia, the Government of Japan decided to conduct a feasibility study on the Jakarta Ring Road Project and Japan International Cooperation Agency (JICA) carried out the study.

Noting that the Jakarta Ring Road Project has a vital bearing on the future urban transportation system in the metropolitan Jakarta area, the Agency dispatched a preliminary survey team to Indonesia in December 1976 for planning and preparation of the feasibility study, and further sent, from March 1977 to May 1977, a supervisory group headed by Mr. Shoji Miyazaki, Deputy Director-General for Engineering Affairs, Planning Bureau, Ministry of Construction and a study team headed by Mr. Hideo Chiba.

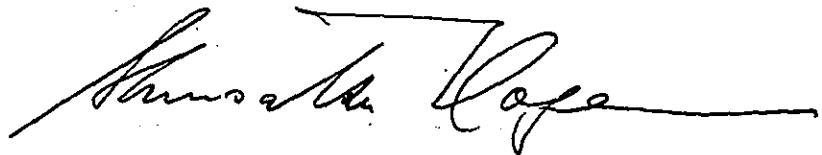

While in Indonesia, the study was carried out smoothly with the close and unlimited cooperation of the competent Indonesian authorities. After its return to Japan, the team engaged in related studies, of which the results are compiled into this report.

In preparing the report, we have conducted not only economic and technical feasibility study but also the feasibility study, in compliance with the request of the Indonesian Government, of the Project in the case of its being implemented as a toll road.

I sincerely hope that the report would contribute to the socio-economic development in the metropolitan Jakarta area and at the same time serve for enhancement of the friendly relations between the two countries.

I would like to take this opportunity to express my heartfelt appreciation to all the members who have participated in this study and to all the authorities concerned in the Republic of Indonesia.

March 1978

Shinsaku Hogen
President
Japan International Cooperation Agency

C O N T E N T S

| Conclusion and Recommendation | |
| Chapter 1: Present Situation of Study Area | |
| 1-1 | Conditions of the Study Area 1- 1 |
| 1-2 | Administrative Division and Zoning 1- 2 |
| 1-3 | Population 1-10 |
| 1-4 | Economic Activities 1-17 |
| 1-5 | Goods Flow 1-25 |
| 1-6 | Existing Traffic Situation and Traffic Survey 1-44 |
| 1-7 | Existing Land Use Situation 1-57 |
| | |
| Chapter 2: Land Use Plan | |
| 2-1 | Review of Reports Available from the Aspect of DKI Jakarta Land Use 2- 1 |
| 2-2 | Forecast of Population and Employment 2- 7 |
| 2-3 | Land Use Planning along the Ring Road Alignment 2-23 |
| 2-4 | Arterial Road Network 2-37 |
| 2-5 | Land Use Planning, DKI Jakarta 2-42 |
| 2-6 | Forecasted Figures by Zone 2-56 |
| 2-7 | Regulation and Guidance on Land Use Plan 2-73 |
| | |
| Chapter 3: Technical Study and Analysis | |
| 3-1 | Geological Analysis 3- 1 |
| 3-2 | Material Surveys 3-10 |
| 3-3 | River and Hydrological Analysis 3-14 |
| | |
| Chapter 4: Design Criteria and Alternatives | |
| 4-1 | General 4- 1 |
| 4-2 | Design Criteria for Main Route 4- 4 |
| 4-3 | Design Criteria for Interchange 4-14 |

| | Page |
|-------------------|---|
| 4-4 | Analysis on the Number of Traffic Lanes 4-31 |
| 4-5 | Comparative studies on the Planning of the Main Route 4-33 |
| 4-6 | Comparative Alternatives on Interchange 4-43 |
| 4-7 | Summary of Comparative Alternatives 4-66 |
| Chapter 5: | Forecast of Future Traffic Volume |
| 5-1 | Method of Forecast and Alternatives 5- 1 |
| 5-2 | Indicators and Car Ownership by Zone 5-11 |
| 5-3 | Development Plans and Future Transport Network 5-20 |
| 5-4 | Establishment of 1976 O-D Matrices 5-22 |
| 5-5 | Estimation of Passenger Vehicle Traffic Generation 5-40 |
| 5-6 | Estimation of Vehicle Trip Generation of Goods Vehicles 5-49 |
| 5-7 | Estimation of Traffic Distribution 5-62 |
| 5-8 | Traffic Assignment Calculation 5-64 |
| Chapter 6: | Preliminary Design |
| 6-1 | General 6- 1 |
| 6-2 | Route Alignment Design and Rough Route Description 6- 3 |
| 6-3 | Design of Major Structures 6-13 |
| 6-4 | Interchange Planning 6-23 |
| 6-5 | Pavement Design 6-49 |
| Chapter 7: | Construction Cost Estimates |
| 7-1 | Estimation Criteria 7- 1 |
| 7-2 | Unit Cost 7- 3 |
| 7-3 | Unit Cost by Work Item 7- 6 |
| 7-4 | Computation of Land Acquisition and Compensation Costs 7- 7 |
| 7-5 | Rough Estimation of Construction Cost 7- 8 |
| 7-6 | Computation of Road Maintenance Cost 7-13 |

| | Page |
|--|-------|
| Chapter 8: Construction Schedule | |
| 8-1 Establishment of Implementation Schedule | 8- 1 |
| 8-2 Whole-route Construction and Stage Construction | 8- 5 |
| Chapter 9: Economic Analysis | |
| 9-1 Vehicle Operation Cost | 9- 3 |
| 9-2 Time Value | 9- 7 |
| 9-3 Congestion Cost | 9- 7 |
| 9-4 Direct Benefits | 9- 8 |
| 9-5 Indirect Benefits (Study on social impact and development impact) | 9-13 |
| 9-6 Toll | 9-13 |
| 9-7 Benefit-cost Analysis | 9-16 |
| 9-8 Sensitivity Analysis | 9-26 |
| 9-9 Economic Analysis on the Stage Construction Alternatives | 9-27 |
| Chapter 10: Financial Analysis | |
| 10-1 Toll System and Toll Collection System | 10- 1 |
| 10-2 Rough Estimates of Operation Cost | 10- 2 |
| 10-3 Financial Cost and Revenue | 10- 3 |
| 10-4 Analysis of Repayment Plan | 10- 4 |

LIST OF TABLES

KEY MAP

MAP OF PROJECT AREA

CONCLUSION AND RECOMMENDATION

Conclusion and Recommendation

In and around the metropolitan Jakarta, there are now three inter-urban expressways planned as tollways to serve as trunk transportation roads for the metropolitan, and some sections are scheduled to be put into operation by this year.

The Jakarta Ring Road, which is the road under study, will, together with other intr-urban toll roads, serve as distributor roads for these trunk radial expressways and will also serve as a bypass of the metropolitan.

The Ring Road is basically a 4-lane-access-controlled road of expressway standard with a total length of about 48 km, which runs along the periphery of the metropolitan Jakarta, forming an outer circular road to divert the traffic into the urban center, and, in conjunction with the change of trend in the urban traffic direction, it is anticipated that the road will have ample impact on the development of the periphery of the city.

The results of this study show that the implementation of the Ring Road project is practical and that the construction and operation of the road as a toll road is viable.

The conclusion of the study are summarized below:

1. The proposed road is planned as a 4-lane road with a design speed of 120 kph and sufficient allowance is provided for future expansion into six lanes.
2. The typical cross-section of the road is as follows.
3. In the case that the whole route is implemented in the package, the volume of earthworks is about six million M³.
4. As for the initial investment, taking into consideration an escalation factor of 7%, the total amount will be 290 - 320 million US\$ in the case of implementation at one stage, or about 89 - 200 million US\$ in the case of stage construction which includes also partial operation of completed sections at the early stage.

TYPICAL CROSS SECTION SCALE 1 : 200

4 - LANE TWO WAY (V=120 km/h, 100 km/h)

6 - LANE TWO WAY (V = 100 km/h)

FILL

| H (m) | N : 1 |
|-------------|-------|
| 0 ≤ H < 2.5 | 4 : 1 |
| 2.5 ≤ H < 4 | 3 : 1 |
| 4 ≤ H | 2 : 1 |

CUT

| H (m) | N : 1 |
|---------------|---------|
| 0 ≤ H < 2.5 | 3 : 1 |
| 2.5 ≤ H < 4.0 | 2 : 1 |
| 4.0 ≤ H | 1.5 : 1 |

5. The results of economic analyses as shown below, indicate that the project is economically feasible.

| | <u>B/C Ratio</u> | | <u>I.R.R.</u> |
|------------------------------|----------------------|---------------|---------------|
| | <u>Discount Rate</u> | | |
| | <u>at 12%</u> | <u>at 15%</u> | |
| (i) Whole route construction | 2.24 | 1.61 | 17.5% |
| (ii) Stage construction | 1.67 | 1.20 | 16.1% |

6. Since the amount of investment is enormous, it is recommended that from the point of regional distribution of national capital investment, the road should be implemented as a toll road instead of an ordinary national highway.
7. A trial calculation of the internal rate of return of the project in the case of its being implemented as a toll road shows that a high rate of 18.2% is obtained. The results also show that the project will be repayable within a period of 20 - 30 years, but experience shows that the actual period of repayment of toll roads is usually shorter than the period calculation during the study. It is recommendable that the possibility of pooling the financial account of all intra-urban toll road should be studied in the case that an earlier repayment period is desired.

In the stage of final engineering and further studies, it is recommended that additional studies be made, taking into consideration the following points.

1. Although the coastal road and the extension from the interchange with the Jakarta - Tangerang Highway are some of the road sections excluded from the road network taken up in this study, these sections should be considered as an integral part of the Ring Road system, and should be included in future additional studies.
2. The timing and sequence of implementation of the road sections should be decided after overall assessment of the role of the urban transport network in the metropolitan of Jakarta.

3. The toll system to be adopted should form part and parcel of the overall toll system for the whole metropolitan, and sufficient consideration should be made keeping in view the actual situation of operation of the Jagorawi Highway and the study results for the Intra-urban Tollway Study, before the final toll system and toll collection system is decided for the Ring Road.
4. Furthermore, in the establishment of the basic transportation plan of the metropolitan Jakarta, a component of which is the Ring Road, special attention have to be paid to the following points regarding the landuse plan.
 - (1) The "urban center dispersal pattern" is the basic concept adopted with regards to the landuse plan in this study and should be promoted. The partial opening of the Ring Road shall be taken into consideration as the impact to developments of urban nucleus in the periphery of the metropolitan Jakarta, with participation of the government.
 - (2) It is possible to locate several sub-CBD at the outer side of the Ring Road. However, it is necessary to guide the implementation of the plan through identifying the role of tertiary services for the Kampung inhabitants in the important roles of Kampung, with proper policy and attention.
 - (3) It is of great importance that an effective policy to realize the landuse basic concept considered in this study be established, and the landuse plan shall be put into effect at an early data, and the development policy shall be formulated, controlled and guided.

The Arterial Road Network in Jakarta and Its Surrounding Area

In DKI Jakarta and its surrounding area, three regional highways have been proposed from DKI Jakarta to Bogor, Tangerang and Cikampek as tollways, and the first one is under construction at present to be opened for public use partially in this year, whereas the second and the third are under detailed design service.

Respecting those conditions, the Intra Urban Tollway System and the Ring Road have been planned to avoid the anticipated serious traffic distribution problems in DKI Jakarta caused by the incoming traffic flow induced by these regional highways.

These highways form the arterial road network in the DKI Jakarta region, and some priority of construction have been recommended as the better solutions for the area as shown in the following map. This study has been carried out to further the recommendation mentioned above, stressing that the supplementary collector/distributor network must be largely improved together with the intra urban tollway construction, in order to channel traffic flows into their final destinations.

The Role of Ring Road for Jakarta

DKI Jakarta as the Capital of Indonesia has been growing rapidly and a continuous urbanization has taken place since 1945. Its population was recorded at about 600,000 in 1945 and increased to about 5,000,000 in 1975. Being the capital of a developing nation, coping mainly with the increasing demand, Jakarta is growing into a metropolis with expanding activities and a rapid increased provision of public facilities and public services is needed.

But Jakarta does not function as it is supposed, and its main reasons are:

- a) Lack of road network within and surrounding DKI Jakarta resulting in a high transportation cost which confines people to have all their activities within the city in order to reduce the transportation cost.
- b) The disorganized transportation pattern makes it impossible for Jakarta to exercise an efficient and effective function as a terminal of distribution services.
- c) The improper location of activity centers and inadequate land use.
- d) The unfavourable condition of transportation facilities within its economic region.

To solve transportation problems, a proper comprehensive plan for the DKI Jakarta road network system is needed. The fast growth would always be followed by an increase in public and private facilities, which from the view of expanding road networks, becomes an obstacle resulting in high cost of construction components, such as land acquisition, demolition, special structure, etc. For the further development of the city, if a proper plan has not been formulated, the development of road networks would not be economically justified, or might not possibly be realized at all, and it means that transportation network can no more support the fast increase in the amount of activities in this growing city.

The existing infrastructure does not meet the need, as only 1.39% of the surface of Jakarta consists of passable roads, against that of 10% in Singapore. New roads being built to release the stress on particular roads are not always based on a sound concept, and failure to take future demands into considerations, often result in shifting of traffic jams from one place to another.

The JABOTABEK urban area development plan formulated to legalize the control, directives and structural system for Greater Jakarta can, in some sense, be a mean to deconcentrate crowded areas by providing a greater urban area. On the same line of the concept, intensive studies on the desired pattern of transport demands will ensure a sound base for a transportation network system. This kind of general plan has to be set up before any implementation takes place, in order to synchronize the system and steps toward a more balanced development pattern over the wider area. At the same time, the existing network should be improved to cope with incidental needs and future demands. This system of roads may consist of ring and radial arterials supported by sufficient collectors and local roads.

The major system is intended to distribute traffic entering the heart of the city or any other part of the city where most of the activities and facilities are concentrated.

The total system will also promote a proper and balanced growth of the city network through the planned diversion of traffic. The capacity of the whole system may rise to its optimal level and give substantial contribution to serving transport demands.

The limited access characteristics of the major road system will minimize a ribbon development and saturation by local traffic. The collector and feeder roads serve to open and connect new areas within the nucleus, forming a part of the system to create favorable condition of the area for the further development.

The major system should be a part of the rural highway arterial system to accommodate the incoming traffic from neighbouring cities such as Tangerang, Bogor and Bekasi as well as Cikampek and Cirebon. The

increasing traffic to Jakarta has caused rural transportation problems in recent years and steps are being taken to solve the problems.

Some new roads have been implemented (Jagorawi 4-lane-full-controlled-access freeway, Bekasi - Jakarta 4-lane-highway, Tangerang-Jakarta 4-lane-highway) and others are still in the phase of study. With the development of the rural arterial highways around DKI Jakarta, the inner DKI Jakarta has to be prepared to accommodate such increase of the incoming traffic.

When the whole system of the infrastructure is realized, the inter-nucleus system (in JABOTABEK urban development area) will be fully supported and might be developed intensively and balanced as planned.

CHAPTER 1 PRESENT SITUATION OF STUDY AREA

The analysis on the present situation of the study area, which includes the city of Jakarta and its surrounding region, is made on the geophysical, economic transport and landuse aspects.

1.1 Conditions of the Study Area

(1) Physical features

The study area is situated on the northwest region of Java Island, and its northern side facing the Java Sea is a flat plain. While towards the south it rises to form the Prancak Plateau, so that it is a gradually sloping formation from the plateau down to the sea. On the slope, many rivers flow towards the sea at the north, forming an alluvial plain which makes very wide rice fields.

Jakarta City is situated near the Equator, being 6° south in latitude, and is located partly on the alluvial plain at the mouth of Chiliwong River and partly on the slope. The project road runs in a semi-circle from the flat plain on the east to the west end of the city, running through the gradual slope to the south.

(2) Climate

The average temperature of the study area ranges from 26.5 C to 27.5 C throughout the year and the average humidity is in the range of 75% to 85%, so that the study area is tropical in climate with high temperature and high humidity. The months of May to October are the dry season when the rainfall is comparatively less but the months of November to April are the rainy season with heavy precipitation. Due to the effect of the monsoon, the prevailing wind direction is north and northeast in the dry season and west and northwest in the rainy season.

Table 1-1 Climate of Jakarta (1975)

| Month | Average Temperature (°C) | Normal Humidity (%) | Normal Rainfall (mm) | Wind Direction | Wind Velocity (m/sec) |
|---------|--------------------------|---------------------|----------------------|----------------|-----------------------|

1.2 Administrative Division and Zoning

The Jakarta Ring Road is situated in the periphery of Jakarta. In a short term, it will serve as a bypass and distributor and collector road for the city center of Jakarta, and in the long term, this will form the main trunk road of Jakarta.

The zoning for the purpose of the study is made of the city of Jakarta and its sphere of influence taking into consideration those functions of the ring road. Full consideration is also made to the present administrative division, the future development plan, the present and future road networks, the past studies such as JMATS, SST etc.

The zoning results are as follows:

| | |
|-----------------------|----------|
| Total number of zones | 66 zones |
| Jakarta city | 41 zones |
| Tangerang Province | 7 zones |
| Bogor Province | 8 zones |
| Bekasi Province | 6 zones |
| Others | 4 zones |

The list of zone code and the zoning map are respectively shown in Table 1-2 and Fig. 1-2.

1.3 Population

1-3-1 Total Population

The total population of Indonesia was 132 million in 1975 and the growth rate over the previous year was 2.4% which showed an slight increase from 2.0% for the year 1950. This may be due to the fact that the decrease in death rate through medical, technological improvement has exceeded the reduction in birth rate throuh family planning.

The population of Java Island for the year 1975 was 83.5 million and the growth rate was about the same as the national average. That is, the growth over previous year has increased slightly from 2.0% in 1950 to 2.2% in 1975.

Table 1-3 Population Development in Jakarta Region, Java/Madura and Indonesia

| | Indonesia | | Java/Madura | | Bo. Ta. Bek. | | D.K.I. Jakarta | |
|------|-------------------------|--|-------------|-----|--------------|-----|----------------|-----|
| | Population (x 1,000) | Growth Rates for each 5 Years, (%) | | | | | | |

Source: Statistical Pocketbook of Indonesia
Statistical Year Book of Jakarta, Bappemka Bogor

The trend of increase in population of the city of Jakarta (DKI) is as shown in Fig. 1-3, showing that the population has reached 5.4 million in 1975. During the period of confusion after the Pacific War and also the year 1958, the trend showed a series of non-continuous rapid growth. However, in recent years, the growth rate showed a stable 4.3% of which the natural increase was estimated at 2.0% so that 2.3% was accounted by social increase, which is mainly due to the influx of population from the rural area of Java Island into the city.

The total population of the neighboring provinces of Bogor, Tangerang and Bekasi was 4 million, which showed an increase of 2.2% over the previous year, due mainly to natural increase.

The trend of changes of population of Jakarta by districts is as shown in Table 1-4, where it can be seen that the population increase has stagnated in Pusat District, but the Barat, Selatan and Timur Districts showed very rapid increase.

The trend of increase of the population of the Bogor, Tangerang and Bekasi Provinces are listed in Table 1-5, where the increase was phenomenal for all provinces.

1-3-2 Population by Stratum

The population of Jakarta may be largely classified by income level into the following strata.

| | |
|----------------------------|-----|
| A. Extreme poverty stratum | 20% |
| B. Poverty stratum | 40% |
| C. Low income stratum | 25% |
| Middle income stratum | 10% |
| High income stratum | 5% |

The housing situation in Jakarta may be statistically classified into the 3 groups of Temporary, Semi-permanent and Permanent.

The temporary housing roughly corresponds to the extreme poverty stratum and also part of the poverty stratum of population. The semi-permanent housing corresponds to the major part of the poverty stratum. The permanent housing corresponds to the low,

middle and high income strata.

The temporary housing has been greatly improved in recent years. By district, it is seen that the share of temporary housing is largest in Utara District.

The public transport system is mainly influenced by the residents of the temporary and semi-permanent housing while the private personal means of transport is considered to be mainly related to the occupants of Permanent housing.

1-3-3 Employed Population by Place of Residence

Of the population in Jakarta, the employment in tertiary industry occupied the largest share of about 80% of the total employed population, while the share of primary industry occupied only 3%. The details are as shown in Table 1-7.

In the provinces of Bogor, Tangerang and Bekasi, the primary and tertiary industries each occupied equal share of about 43%.

The details are as shown in Table 1-8.

The employment situation in 1971 for the total population of 4,576 thousand in Jakarta may be summarized as follows:

| | |
|--|---------|
| Percentage of labour population in total population | : 29.5% |
| Percentage of employed population: | 25.8% |
| Unemployment rate | : 3.7% |

The same for the total population of 3,761 thousand in the provinces of Bogor, Tangerang and Bekasi are as follows:

Percentage of labour population
in total population : 26.2%
Percentage of employed population : 20.3%
Percentage of employed population : 5.9%

Table 1-7 Employed Population of Jakarta (1971)

(unit: 1,000 persons)

1.4 Economic Activities

1-4-1 Economic Growth and Industrial Structure of Indonesia

Indonesia has greatly exceeded its target of economic growth, recording an average annual real growth rate of over 7% for the first Five Year Plan Period (First Repelita 1969-1973 which started from April, 1969.

However, the petroleum crisis from the fall of 1973 brought about stagnation in world economic activities, and consequently the economic growth of Indonesia also slowed down in pace.

In the second Five Year Plan (Second Repelita) which started from 1974, the target for the annual growth in gross domestic products was set at 7.5%, so that the GDP in the fiscal year 1973/1974 of 6,224.4 billion rupiah was estimated to be increased to 8,935.6 billion rupiah for 1978/1979.

However, international economic and monetary crisis also greatly affected the economy of Indonesia so that the 7.4% growth in GDP for 1974 dropped to 5.2% for 1975. This was due to the drop in export volume of crude oil, timber, etc., and the rise in the price of imported goods. Also, the price of commodities, which had hitherto been comparatively stable, also showed a rapid increase for the years 1973 and 1974 so that the rates of increase over the previous years were respectively recorded at 27.4% and 33.3%.

The depression continued in 1975, and could not recover throughout the year. Meanwhile, the production of crude oil, which is the largest foreign exchange earner, also had to be reduced due to stagnant overseas demand.

The foreign currency reserves of Indonesia fell drastically from 2,030 million dollars in October 1974 to 580 million dollars in the end of 1975, but had shown recovery since 1976. Following the world economic recovery of the world developed nations, the economy of Indonesia also recovered gradually from 1976. In foreign trade, active promotion measures were taken for stimulation of export and the effects had been favorable. Export

of crude oil and timber particularly, recorded an increase of respectively 25.4% and 28.3% over the previous year. Restrictive measures against import also bore and the volume of import had decreased compared to the previous year so that considerable surplus in balance of trade could be expected. If the economy should continue to recovered, it will not be impossible to reach the target of the second Repelita.

The target annual growth rates for the various sectors in the second Repelita were 4.6% for agriculture, 13% for industry, 9% for mining, 10% for transport and communication, 15% for public works, and 8% for other sectors, and the average growth of GDP was projected at 8%, as seen from Table 1-9.

Table 1-9 Projected Gross Domestic Product
(Repelita II)

| | 1973/74 (as % of GDP) | 1978/79 (as % of GDP) | Annual Growth Rate(%) |
|--|--------------------------|--------------------------|-----------------------------|
| 1. Agriculture, forestry & fishery | 40.2 | 35.6 | 4.6 |
| 2. Mining & quarrying | 9.2 | 9.9 | 9.0 |
| 3. Manufacturing | 9.8 | 12.5 | 13.0 |
| 4. Construction | 3.7 | 4.0 | 9.2 |
| 5. Transportation & Communication | 4.1 | 4.7 | 10.0 |
| 6. Others | 33.0 | 33.3 | 7.6 |
| 7. GDP | 100.0 | 100.0 | 7.5 |
| - At 1973 constant price (billion Rp.) | 6,224.4 | 8,935.6 | 7.5 |
| - At current price* | 6,224.4 | 13,745.0 | 17.2 |

(Note) *Assuming inflation at 9.7% per year.

(Source) Second Five-Year Plan

Agriculture is a very important sector in the economy of Indonesia and top priority was given to this sector in the second Repelita. This is because agriculture occupied 60.3% of the employed people in Indonesia for 1973/74 who are the largest consumer group for domestic products, so that the growth

in agriculture will also bring about the growth of the blooming industry sector.

The share of the industry sector in GDP has been as a constant increase from 8.8% in 1971 to 10.4% and 11.1% respectively in 1974 and 1975. In the second Repelita, the industry sector is envisaged to form the backbone of the future national economy. Thus in the first Repelita, emphasis in the industry sector was put on the construction of agriculture related industries, but in the second Repelita, the emphasis is shifted to the materials processing industry. To promote the development of industry, stress is put on the improvement of the infrastructure and the construction of industrial estates, for which in the second Repelita, plans are made for Jakarta, Cilacap, Surabaya, Medan and Batam.

Production of crude oil and natural gas, the major sources of foreign exchange of Indonesia has realized a growth of 200% from 1966 to 1973 and the targets were established at a 12% annual growth for the first Repelita and 8% for the second Repelita. Production of natural gas is also planned to be greatly increased after the completion of the LNG plant and in line with the rapid pace in the construction of large scale fertilizer factories.

1-4-2 Economic Growth and Industrial Structure in Jakarta

The annual economic growth rate of Jakarta for the period 1969 to 1974 came to nearly 10%. This is considerably higher than the average annual growth in national GDP of about 7%. Meanwhile, the annual population growth of Jakarta for the same period was 4.4% which was nearly double the national average growth rate of 2.4%. This phenomenon caused not only serious fiscal and economic problems but also very grave social problems. On the other hand, great effort was put on the increase of employment opportunity, the protection and fostering of small enterprises and substitute industries for imported products, the promotion of labour intensive industries, the planning of

appropriate landuse and the improvement of infrastructure facilities.

From the point of industrial structure, it is seen that great changes have taken place in the economic activities of Jakarta. The share of agriculture and fishery industry in the gross regional domestic products (GRDP) has greatly reduced from 6.4% in 1969 to 2.4% in 1974, whereas the share of wholesale and retailing industry has from 49.4% to 55.0%.

From the point of economic growth of Jakarta by economic sector, taking the index of 1959 at 100, the index of the agriculture and forest industry fell to 64.5 in 1974. Of this, although agricultural products had decreased, the volume of husbandry and agricultural products had increased, indicating an improvement in the food requirement of the population following the development of the city and the increase of real personal income.

The sectors of most phenomenal growth in the GRDP of Jakarta were wholesale and retailing sector, financing and insurance sector and also the real estate sector, showing respectively an index of 191.8, 192.2 and nearly 200 taking the index in 1969 as 100. The sectors of electricity, gas and water supply, government administration and also services also showed a great increase to an index of 160 to 180, indicating that Jakarta has developed as a commercial, business and service center.

The manufacturing sector for the period 1969 to 1973 had enjoyed a similar growth to that for GRDP. However, for the year 1974, the index for manufacturing sector was 157.2 which was considerably lower than the 174.2 for GRDP. In the second Repelita, plans were provided for the construction of industrial estates in Jakarta, and, considering the masterplan of the city, it is anticipated that the manufacturing sector will continue to occupy an important share in the GRDP.

It is seen that the characteristics of the industrial structure of Jakarta was such that the share of agricultural products in GRDP had decreased and that of wholesale and retailing sector

had increased, whereas the other sectors had remained more or less unchanged through the years except for minor fluctuations. The total production, however, has been constantly on the increase.

The share of GRDP of Jakarta in the GDP of Indonesia had increased yearly from 7.9% in 1969 to 9.6% in 1974, and, as described above, the average annual economic growth rate had reached nearly 10%, accompanied by a corresponding population increase at an average annual rate of about 4%. The constant economic investment in Jakarta over the years had brought about a great economic growth, and the increase in disparity in income between regions had contributed to the inflow of population into Jakarta which makes an estimated social increase in population of about 2%.

Taking such present situation into consideration, the JABOTABEK Study Report and the masterplan for Jakarta had planned the peripheral township of Tangerang, Bekasi, Serpong and Depok as "growth centers" to diversify the population and public and private investments in Jakarta. Also, to develop Jakarta as a national capital and an international city, the importance of maintaining an appropriate balance in economic development of the entire capital region including Tangerang, Bogor and Bekasi had been strongly stressed.

In the masterplan for Jakarta (1965 - 1985), the population of Jakarta in 1975 was estimated at 4.9 million, but in actual fact the forecast was greatly exceeded by the 5.4 million recorded for that year. It can be anticipated that the forecast 1985 population of 6.5 million may also be exceeded much earlier than the target year, and it seems that the limit of capacity of population accommodation of Jakarta will be near. Under such condition, and judging from the plans in the JABOTABEK Report and the masterplan for Jakarta, it may be difficult for the GRDP to maintain a high annual growth of about 10%. On the other hand, it is hoped that the investment and promotion of economic development of the BOTABEK region will serve about the surplus

population from Jakarta and result in a more balanced regional development and diversification of economic function.

From the above considerations, the average annual economic growth rate up to 1980 is assumed to be 9%, that for the period 1980 to 1990 at 8% and from 1990 to 2000 at 7%.

1-4-3 Existing Situation of Car-ownership

As seen in the following tables, the number of vehicles in Jakarta has increased by 1.7 times in 5 years from 1971 to 1975, and the rate of car-ownership per 1,000 population has also increased by 1.5 times.

Table 1-10 Car-ownership in Jakarta

(x 1,000 vehicles)

| | 1971 | 1972 | 1973 | 1974 | 1975 |
|------------------------|-------|-------|-------|-------|-------|
| Passenger vehicles | 95.1 | 103.3 | 115.6 | 131.0 | 152.5 |
| Buses | 5.8 | 6.7 | 7.6 | 8.6 | 9.8 |
| Trucks | 21.9 | 24.9 | 29.4 | 37.8 | 44.7 |
| Total | 122.8 | 134.9 | 152.6 | 177.4 | 207.0 |
| Vehicles/1,000 persons | 26.8 | 28.4 | 30.7 | 34.2 | 38.3 |

(x 1,000 vehicles)

| | 1971 | 1972 | 1973 | 1974 | 1975 |
|------------------------|------|------|------|------|------|
| Passenger vehicles | 259 | 277 | 307 | 338 | 383 |
| Buses | 23 | 26 | 30 | 31 | 35 |
| Trucks | 115 | 131 | 143 | 166 | 196 |
| Total | 297 | 434 | 480 | 535 | 614 |
| Vehicles/1,000 persons | 3.3 | 3.5 | 3.8 | 4.1 | 4.6 |

Comparing to Table 1-10 shows the ownership situation in the whole of Indonesia it is seen that 30% of the national total number of vehicles are concentrated in Jakarta and that the

**Fig. 1 - 4 DEVELOPMENT OF VEHICLE OWNERSHIP
D.K.I. JAKARTA**

**Fig.1-5 RATES OF VEHICLE OWNERSHIP & PER CAPITA
G.R.D.P. IN D.K.I JAKARTA**

rate of ownership of Jakarta is 8 times that of the national average.

In terms of ownership by vehicle type, it can be seen from Fig. 1 that passenger vehicles increase by 1.60 times from 1971 to 1975 with an average annual growth rate of 12.5%, whereas the same for truck is 2.04 times and 20.0% growth rate, and for bus is 1.69 times and 14.0% growth rate.

The growth of the number of trucks was most rapid due probably to the increase in demand for goods transport in Jakarta.

The total growth for all vehicles was 1.69 times from 1971 to 1975, showing a high average annual growth rate of 14.0%.

Generally, the rate of vehicle ownership shows a good correlation with the GRDP per capita, and by computing the parameters of a linear correlation equation for the two factors by regressive analysis, a very good relation was obtained.

Table 1-11 Relation between Per Capita GRDP and Rate of Car Ownership

| | 1971 | 1972 | 1973 | 1974 |
|---|--------|--------|--------|--------|
| Per Capita GRDP (at 1969 constant price) | 57,136 | 59,545 | 64,293 | 71,512 |
| Vehicles/1,000 | 26.8 | 28.4 | 30.7 | 34.2 |

Regressive equation:

$$Y = 0.506 x - 1.915 \quad (R: 0.999)$$

where, X: per capita GRDP in 1,000 rupiah

Y: vehicles/1,000 persons

R: correlation coefficient

The correlation is shown in Fig. 1-4, 1-5.

1.5 Good Flow

1-5-1 Main Commodity Items

The following main commodity items were selected for analysis from the points of availability of data, method of statistical classification, the effect of the volume on goods flow, and also the characteristics of Jakarta as well as the forecast future volume of production and consumption.

- (1) Agriculture, forestry and fishery
 - 1) Agricultural products
 - a. Farm good crops
 - b. Estate crops
 - c. Livestock and its products
 - 2) Fishery products
 - 3) Forestry products
- (2) Industry
 - 1) Food, beverages and tobacco
 - 2) Textile, clothing, paper, furniture and other household wares.
 - 3) Raw materials and auxiliary
 - 4) Cement and other construction materials
 - 5) Iron and steel products
 - 6) Fertilizer and pesticides
 - 7) Fuel
 - 8) Small scale and family manufacture products
 - 9) Others

According to the above classification, computation is made for the production and consumption for the whole of Indonesia from all available data and estimate is also made for the goods flow of Jakarta.

As for mining products, there is no significant production or demand in the city of Jakarta and also the port of Tanjung Priok has not handled any significant volume of mining products so that this item may be neglected as having no effect on the goods flow in Jakarta.

1-5-2 Flow of Main Commodities in Indonesia

The estimation of the flow of the main commodity items was started with the computation or estimation of the volume of production and consumption of each item in Indonesia.

(1) The volume of production of commodities by main items
Of the farm food products, the one item that occupies a great weight in relation to goods flow is rice. However, statistics volume of milled rice, a conversion ratio of 68% is adopted. Other farm food crops include maize, cassava, sweet potato, peanuts, soybeans, fruits, vegetables and potatoes.

According to the agricultural census in 1963, there were 12,260 thousand self-employed agricultural households working for an area of 12,880 thousand hectares. The same census in 1973 showed that there were 14,400 thousand households for a total area of 14,170 thousand hectares, indicating an increase in household of 2,140 thousand and an area of 1,290 thousand hectares over a ten year period. The harvest per unit area also indicated an increase over the past years as seen in the following table, showing that the target of increasing productivity in the agricultural sector in the first and second Repelita were bearing fruit.

Table 1-12 Productivity of Farm Food Crops in Indonesia
(100 kg/ha)

| | 1968 | 1969 | 1970 | 1971 | 1972 | 1973 | 1974 |
|--------------|-------|-------|-------|-------|-------|-------|-------|
| Paddy | 27.97 | 29.39 | 31.06 | 31.70 | 32.10 | 33.43 | 34.81 |
| Maize | 9.83 | 9.42 | 9.61 | 9.92 | 10.44 | 10.75 | 12.23 |
| Cassava | 75 | 74 | 75 | 76 | 71 | 78 | 91 |
| Sweet potato | 58 | 61 | 61 | 62 | 61 | 63 | 88 |
| Peanuts | 7.27 | 7.18 | 7.40 | 7.55 | 7.98 | 6.98 | 7.70 |
| Soybeans | 6.20 | 7.02 | 7.17 | 7.59 | 7.43 | 7.28 | 7.30 |

Source: Statistical Year Book of Indonesia, 1975

(2) Production of estate crops

The Estate Census of 1973 showed that there were 1,801 large estates with an area of 2,220 thousand hectares. Of these, the rubber estates had the largest area of 455.5 hectares

followed by oil palm with 155.7 thousand hectares and sugar cane with 88.2 thousand hectares. However, when the total is taken of the large and small estates, the total production was largest for coconuts which recorded 1,287 thousand tons in 1973, followed by rubber with a dry production of 844 thousand tons, refined sugar with 820 thousand tons, and palm oil with 290 thousand tons. These products accounted for 83% of the total estate crops production.

(3) Livestock and its products

As seen in the following table, the number of livestock showed a general increase since 1970.

Table 1-13 Production of Livestock

(unit: thousand head)

| | 1970 | 1971 | 1972 | 1973 | 1974 |
|---------|-------|-------|-------|--------|---------|
| Cattle | 5,130 | 6,243 | 6,354 | 6,682 | |
| Buffalo | 2,976 | 2,976 | 2,898 | 2,870 | |
| Goat | 6,336 | 6,943 | 7,354 | 7,468 | |
| Sheep | 3,362 | 3,146 | 3,001 | 3,207 | |
| Pig | 3,169 | 3,382 | 2,901 | 4,048 | |
| Horse | 692 | 665 | 680 | 689 | |
| Chicken | - | - | - | 99,769 | 109,679 |
| Duck | - | - | - | 13,810 | 15,879 |

Source: Directorate General of Veterinary Department of Agriculture Ministry.

The number of buffaloes showed a decreasing trend but that of cattle, goat, and horse showed a gradual increase whereas the number of pigs rapidly increased from 1972 to 1973. As for fowls, chickens occupied a very large number.

From the point of the number of livestock slaughtered by region, it is seen that whereas the number of cattle bred in Jakarta was only 5 thousand, the number of cattle slaughtered came to 88.5 thousand, showing that almost all cattle slaughtered in Jakarta were transported from other regions.

The number of livestock slaughtered and the volume of meat production are as shown in Table 1-14 and 1-15.

Table 1-14 Number of Livestock Slaughtered in Indonesia
(1970 - 74) (unit: 1,000/head)

| | 1970 | 1971 | 1972 | 1973 | 1974 |
|---------|------|------|------|------|-------|
| Cattle | 823 | 670 | 724 | 686 | 699 |
| Buffalo | 187 | 166 | 167 | 181 | 178 |
| Goat | 702 | 947 | 549 | 593 | (777) |
| Sheep | 234 | 177 | 218 | 243 | |
| Pig | 427 | 501 | 567 | 560 | 841 |
| Horse | 7 | 3 | 4 | 7 | 6 |

Table 1-15 Production of Meat in Indonesia 1973
(unit: 1,000/head)

| | Java | Outer Java | Indonesia |
|---------|-------|------------|-----------|
| Cattle | 103.2 | 37.6 | 40.8 |
| Buffalo | 22.4 | 17.4 | 39.8 |
| Goat | 24.8 | 9.3 | 34.1 |
| Sheep | 15.1 | 1.1 | 16.2 |
| Pig | 14.8 | 95.0 | 109.8 |
| Horse | 0.8 | 0.7 | 1.5 |
| Poultry | 40.0 | 42.6 | 83.0 |
| Duck | 2.0 | 3.4 | 5.4 |
| Total | 223.5 | 207.1 | 430.6 |

From the production of meat, it is seen that the production of cattle beef in Java was about 3 times that of other region whereas that of pork (pig) was only 15% of other regions. This trend may be deducted for various other regions, indicating the regional difference in economic, cultural and religious conditions.

As for daily products, production is estimate for milk and eggs from statistical data.

Generally, the consumption of husbandary and daily products increases together with the improvement in income and living level, this stimulating the latent production potential in Indonesia. In the second Repelita, the annual rate of livestock and dairy products were planned at 7% for meat, 10% for egg and 11% for milk.

(4) Fishery products

The total fishery haul in Indonesia was 1,390 thousand tons in 1975, of which marine fishery was 994 thousand tons and inshore fishery was 396 thousand tons. A characteristic of fishery in Indonesia is the large share of inshore fishery which occupied 33% of the total haul in 1974. This provides very important source of animal protein for the inhabitants of the inland area where transport is inconvenient. The main regions of fishery production are Sumatra, Kalimantan and Java which accounted for a total of nearly 80% of total haul. Kalimantan and Java together also occupied about 70% of total inshore fishery production, whereas Sumatra occupied about 40% of total marine fishery production as seen in the following table.

The marine fishery production capacity of the Indonesia territory water and neighboring water is estimated to be 5.8 million tons while that of inshore waters is about 1.8 million tons for a total fishery production capacity of 7.6 million tons, showing that fishery is an important food source for the population and the development of fishery is highly expected.

Fishery Production in Indonesia

(in tons)

| | 1971 | 1972 | 1973 | 1974 |
|-----------------|-----------|-----------|-----------|-----------|
| Marine fishery | 820,447 | 836,289 | 860,000 | 893,000 |
| Inshore fishery | 424,108 | 432,620 | 440,000 | 449,000 |
| | 1,244,555 | 1,268,909 | 1,300,000 | 1,342,000 |

The productivity per fisherman in Indonesia is at a low level of about one ton per year, which is considerably lower than the standard international fishery productivity. Under domestic demand and strengthened import, the production is planned at 4% increase per year and export volume planned at 25% increase per year. Also, improvement of water supply, transport and communication and other infrastructures for fishery regions

were also planned. Moreover, plans were also made for the increase of fishery instructors and for provision of financing facilities to the fisherman who are weakest in the financing and technical aspects.

(5) Forestry products

Indonesia is very rich in forestry resources, with an area of 122 million hectares, or 63% of national land area covered with forest. The situation of forestry resources in 1973 by region and by usage are as shown in Table 1-12.

Table 1-16 Situation of Forestry Resources, 1973

(in million hectares)

| Area | Total area of forest land | Designated forest land for | | | | Total |
|-----------------------|---------------------------|----------------------------|------------------------|-------------------------------------|---------------------|--------|
| | | Protection forest land | Production forest land | Protection & production forest land | Nature Conservation | |
| Sumatra | 28,420 | 5,256 | 8,657 | 176 | 1,534 | 15,622 |
| Java & Madura | 2,819 | 835 | 1,745 | - | 280 | 2,895 |
| Kalimantan | 41,470 | 456 | 21,238 | 1,840 | 606 | 24,140 |
| Bali and Nusatenggara | 2,036 | 1,095 | 85 | 68 | 130 | 1,378 |
| Sulawesi | 9,910 | 3,487 | 1,944 | 2,672 | 132 | 8,235 |
| Maluku | 6,000 | - | 1,169 | - | 39 | 1,208 |
| Irian Jaya | 31,500 | - | 590 | - | 320 | 910 |
| Indonesia | 122,227 | 11,535 | 35,429 | 4,691 | 3,084 | 54,742 |

From the above table, it is seen that productive forest area occupied 29% of the total forest area. The production volume in 1963 was 196 million cubic meters but had rapidly increased to 2,635 million cubic meters in 1973, and the annual growth rate after 1968 was 48%, as seen in Table 1-13. In the second Repelita, while increase in production was contemplated, emphasis were also put on the strengthening of forestry industry supervision, foresting, and replanting in order to ensure ef-

efficient usage and to provide protection to the forestry resources, and also to develop the labor force on forestry. For the promotion of export of processed timber, it was also made compulsory for forestry enterprises to construct timber processing factories.

Table 1-17 Timber Production

(in thousand m³)

| Kind of logs | 1963 | 1964 | 1965 | 1966 | 1967 | 1968 | 1969 | 1970 | 1971 | 1972 | 1973 |
|--------------|-------|-------|-------|-------|-------|-------|-------|--------|--------|--------|--------|
| Teak wood | 492 | 474 | 444 | 373 | 424 | 473 | 477 | 568 | 470 | 597 | 676 |
| Jungle wood | 1,469 | 1,396 | 1,241 | 1,550 | 1,540 | 3,355 | 5,729 | 10,331 | 13,236 | 17,120 | 25,671 |
| Total | 1,961 | 1,870 | 1,685 | 1,923 | 1,964 | 3,828 | 6,206 | 10,899 | 13,706 | 17,717 | 26,347 |

(6) Food and beverages

In the manufacturing industry sector, the food and beverages had shown very rapid development, growing at an annual rate of 9% during the first Repelita period. 31% of this food and beverage industry is of middle size enterprise, and the industry occupied a total of 35% of the labor force in all manufacturing industries. However, since small scale food enterprises are not included, it is estimated that the total labor force including small enterprises of the food and beverages industry came to 40% of the total labor force. Also, the production amount of food products had a share of 50% of all manufacturing industry. From the 1973 statistics, it is seen that the processing of rice, fish meat and other canned food made up 67% whereas tobacco production came to 27% of all food and beverages production.

In 1970, rice, refined sugar, palm oil, tapioca and tea processing were the main items, having a 90% share in the food and beverages industry. From 1971, such new industries as ice manufacturing, meat processing noodle-making, bread bakery came into the picture and factories for canning of fish, and vegetables, processing of powder milk, flow and biscuits also

began to appear. Also, factories for frozen fish and prawns were rapidly developed, and investment in food and beverages industry had, after the first Repelita, continued to be accorded high priority within the manufacturing industry in the second Repelita, in which the annual growth rate is planned at 10.4%.

(7) Textile, clothing, paper, furniture & other household were products.

In this category are included the manufacture of textile, leather, paper, furniture, rubber products, chemical and plastic materials, and also household wares.

This category had a 30% share of production amount in the manufacturing industry and absorbed 11.5% of the labor force.

The textile industry saw satisfactory development in the first Repelita so that cloth and woven thread respectively increased by 100% and 87% during the 5 years period. Generally, the textile industry depends mainly on foreign supply in raw materials, semi-processed materials and also its capital investment, and the ratio are as shown below.

| Materials, Capital | Import ratio |
|--------------------|--------------|
| Cotton | 99% |
| Chemical fibre | 100% |
| Woven thread | 50% |
| Dyes and chemicals | 95% |
| Machinery | 99% |

The scale of textile industry in Indonesia is generally small and 70% of the factories are with less than 50 machines in each factory. It is planned that the production of cloth and woven thread would increase by respectively 31% and 71% by the end of the second Repelita period, in 1978/1979.

The most important item in the paper industry is pulp industry, for which the production in the first Repelita were as follows.

| Year | Production (ton) |
|---------|------------------|
| 1969/70 | 17,000 |
| 1970/71 | 22,000 |
| 1971/72 | 30,000 |
| 1972/73 | 39,000 |
| 1973/74 | 40,000 |

The production of other household wares from chemical and plastic materials has a great share in this category, but since the production of these materials will require enormous investment in the basic industry, the development in this category cannot be too greatly expected.

(8) Raw materials and auxiliary

In this category are included the chemical materials, plastic materials, chemical fibre and timber materials for the paper industry. For the petro-chemical industry, a factory with a yearly production capacity of 20 thousand tons of polypropylene was constructed at Plaju and its operation commenced in 1973. Furthermore, studies were made for the production of ethelene, propylene from naptha or natural gas. Production of caustic soda, soda ash and hydrochloric acid from salt is also underway. In the second Repelita, efforts are made to improve the quality of these products.

(9) Cement and other construction materials

In 1972, there was only one cement factory in Gresik, Surabaya with an annual production capacity of 500 thousand tons. There are plans to construct a new factory of a capacity of 500 thousand tons in Cibinong, Bogor, another of 400 thousand tons capacity in Cilacap, and also to expand the Gresik factory by another 500 thousand tons. There are also plans for cement factories in Southern Sumatra, Northern Sumatra and Aceh. The production and import volume of cement factory in the first Repelita are as follows.

(in 1,000 tons)

| Year | Production | Import | Total |
|---------|------------|--------|-------|
| 1969/70 | 541 | 513 | 1,054 |
| 1970/71 | 568 | 703 | 1,271 |
| 1971/72 | 530 | 919 | 1,449 |
| 1972/73 | 722 | 1,083 | 1,805 |
| 1973/74 | 850 | 1,100 | 1,950 |

In the second Repelita, the production and demand are planned as follows, forecasting self sufficiency by 1977 and allowance for export in subsequent years. However, it is reported that

there is some delay in the planning or construction of new factories which were planned to go into operation by 1975.

Table 1-18 Targets in Repelita II

(in 1,000 tons)

| Year | Production | Demand | Import |
|---------|------------|--------|--------|
| 1974/75 | 970 | 2,200 | 1,310 |
| 1975/76 | 1,650 | 2,660 | 1,010 |
| 1976/77 | 3,125 | 3,135 | 10 |
| 1977/78 | 4,363 | 3,710 | (655) |
| 1978/79 | 5,135 | 4,395 | (740) |

Other construction materials include timber, brick stone and metallic construction materials and the production volume had a share of 25% in weight in all productions.

(10) Steel and iron products

There are about 20 iron scrap reclaiming factories which manufacture reinforcing steel and pipes. However, all iron and steel materials depend on import, and the imported materials are used for galvanizing or pipe production or for fabrication.

The planned productions in the second Repelita are as follows:

| Year | Steel pile | Steel pipe | Others |
|---------|------------|------------|--------|
| 1974/75 | - | 35 | 200 |
| 1975/76 | - | 50 | 250 |
| 1976/77 | 100 | 60 | 350 |
| 1977/78 | 150 | 75 | 550 |
| 1978/79 | 150 | 100 | 650 |

(11) Fertilizers and pesticides

For fertilizer production, there are the Petrokimia factory in Gresik, East Java and the Pusri factory in Palembang and the production capacities are as follows:

| | (tons/year) | | |
|-------------------|-------------|---------|----------|
| | Petrokimia | Pusri I | Pusri II |
| Urea | 60,000 | 10,000 | 380,000 |
| Ammonium Sulphate | 120,000 | - | - |
| Ammonia | 7,000 | - | - |

Promotion of fertilizer production occupies a very important position in Indonesia in relation to agricultural development,

and since 1970, plans have been made to construct factories for Urea production with the abundant natural gas as its material in order to turn the annual import into export. Thus in second the Repelita, new factories for fertilizers are planned in West Java, and East Kalimantan, respectively with daily production capacity of 1,000 tons and 1,500 tons. The East Kalimantan factory is planned to have daily production of 1,000 tons of urea and 500 tons of other fertilizers.

(12) Fuel production

The flow of fuels, the petroleum products which has a great effect on the goods flow in Jakarta are mainly conveyed into the city via the Tanjung Priok Port. However, since the volume of oil refined in Java Island has only a meager share of 1.8% of the national total, the flow of fuel into Jakarta by land transport may be completely neglected.

Consumption quantity in Indonesia by commodity items

The volume of consumption of each commodity item is calculated from the data of the previous paragraphs by adding the production volume and import volume and deducting the export volume and the results are listed in Table 1-19.

1-5-3 Flow of Main Commodities in Jakarta

The flow of main commodities in Jakarta were also calculated for each item by calculating the production and consumption of the items from statistical data in order to grasp the pattern of goods flow from the balance of production and demand.

(1) The volume of production of commodities by main items

1) Farm food crops production

The share of agricultural production in GRDP of Jakarta fell from 6.41 to 2.40% in 1974. The production index also fell to 64.46 in 1974 assuming an index of 100 for 1969. The production of crops particularly showed a decrease whereas the production of livestock, dairy and fishery products was on an increasing trend.

Table 1-19 Production and Consumption of Goods in Indonesia, 1973

| Goods | Production | Import | Export | Consumption |
|------------------------------------|------------|-----------|------------|-------------|
| (unit: ton) | | | | |
| Farm Food Crops: | | | | |
| Rice | 19,101,777 | 1,862,700 | | 21,064,477 |
| Maize | 3,689,802 | | 181,280 | 3,508,522 |
| Cassava | 11,185,592 | | 76,688 | 11,108,904 |
| Sweet potato | 2,386,764 | | | 2,386,764 |
| Peanuts | 290,104 | | 21,390 | 268,714 |
| Soybeans | 541,040 | | 36,001 | 505,039 |
| Fruits | 4,500,000 | | 441 | 4,499,559 |
| Vegetables | 2,401,000 | | 30,380 | 2,370,620 |
| Potatoes | 178,000 | | 3,668 | 174,332 |
| Estate Crops | 3,899,800 | | 1,419,900 | 2,479,900 |
| Animal Husbandry: | | | | |
| Livestock slaughtered | 337,307 | | 24,497 | 312,810 |
| Eggs | 137,259 | | | 137,259 |
| Fresh milk | 31,093 | | | 31,093 |
| Meat | 430,600 | 1,612 | | 432,212 |
| Fishery Products | 1,300,000 | | 5,868 | 1,294,132 |
| Forest Products | 21,077,600 | | 14,770,180 | 6,307,420 |
| Industrial Products: | | | | |
| Food, beverages & tobacco | 6,994,485 | 196,400 | 56,172 | 7,134,713 |
| Textile, clothing, furniture, etc. | 674,743 | 448,100 | | 1,122,843 |
| Raw materials & auxiliary | 2,726,423 | | | 2,726,423 |
| Cement | 752,158 | 1,496,800 | | 2,248,958 |
| Other construction materials | 3,594,562 | | | 3,594,562 |
| Iron & steel products | | 585,600 | | 585,600 |
| Fertilizer & pesticides | 254,822 | 673,700 | | 928,522 |
| Fuel | | | | 8,000,000 |
| Small & household manufacturing | 9,841,312 | | | 9,841,312 |
| Other manufacturing products | 208,566 | 3,253,100 | | 3,461,666 |

The annual production of farm food crops is as shown in the following table which shows that except for 1970, the production of rice is generally stable, although maize has greatly decreased and the production of cassava, peanuts and sweet potato for 1974 has dropped to one-tenth of that in 1969. Other products are soybeans and greenpeas, etc., but their production is too small to warrant any notice.

Table 1-20 Production of Farm Crops
(ton)

| CROPS | 1969 | 1970 | 1971 | 1972 | 1973 | 1974 |
|--------------|---------|---------|---------|---------|---------|---------|
| Paddy | 45,367 | 37,354 | 46,350 | 45,326 | 45,186 | 48,185 |
| Maize | 3,879 | 596 | 696 | 493 | 143 | 90 |
| Sweet potato | 7,315 | 7,145 | 3,150 | 1,701 | 836 | 1,171 |
| Peanut | 2,532 | 1,477 | 541 | 499 | 271 | 238 |
| Vegetable | 172,757 | 236,170 | 218,573 | 113,408 | 110,438 | 112,862 |
| Fruit | 106,981 | 107,000 | 127,397 | 98,835 | 60,678 | 47,074 |

Following the growth of commercial and industrial activities in Jakarta, the production of farm crops is expected to further decrease although cultivation of rice and vegetable will continue in the suburb of Jakarta.

2) Estate crops production

As estate crops are almost not produced in Jakarta, it is expected that the goods flow will be mainly the transport of the products from other areas to meet demand in Jakarta.

3) Livestock and its products

A great different is seen between the number of livestock bred and that slaughtered in Jakarta, indicating a flow of very large quantity from other regions into Jakarta.

The livestock population and the number slaughtered in 1973 are as follows:

| Livestock | Population | Slaughtered | (heads) |
|-----------|------------|-------------|---------|
| Cattle | 5,000 | 88,500 | |
| Buffalo | 4,000 | 16,500 | |
| Goat | 14,000 | 60,000 | |
| Sheep | 14,000 | 13,300 | |
| Pig | 32,000 | 110,000 | |
| Horse | 2,000 | 36 | |

Source: Statistical Year Book of Indonesia, 1976.

In the conversion into weight of meat, the following unit weight per head of livestock is assumed.

| | |
|---------|--------|
| Cattle | 310 kg |
| Buffalo | 360 kg |
| Goat | 35 kg |
| Sheep | 35 kg |
| Pig | 52 kg |
| Horse | 166 kg |

Chicken cultivation is carried by middle size enterprises in the periphery of Jakarta and the production is increasing. The number of chicken for food use increased from 780 thousand in 1969 by 15 times to 11.51 million in 1974. The production of eggs has consequently also increased. On the other hand, no significant change is seen in the production of milk which remained at around 4 million liters from 1969 to 1974.

4) Fishery products

The total fishery haul of Jakarta in 1973 was about 10 thousand tons in 1973 of which 70% was marine fishery and 30% inshore fishery.

Jakarta is the largest consumption market of fisher products in Indonesia and is also the center of collection and distribution of the product within Indonesia.

Considering the anticipated future increase in unit consumption following improvement in income and living level, it can be expected that future consumption will further increase.

Supply of fresh fishery products to Jakarta is made from five landing points and the Pasar Ikan fish market is the largest supply base, so that some supply to the other landing points are also transferred to Pasar Ikan for sale.

Dried salted fish is mainly transported by small sale boats from Sumatra and Kalimantan and unloaded in Pasar Ikan or Kali Baru, but a small portion is transported from the central and western region of Java Island to Jakarta by trucks.

Fresh water fish is transported by truck from central and western region of Java into Jakarta.

Pasar Ikan is the largest fish unloading port of Indonesia but the facilities are old, narrow and of poor sanitary conditions and is lacking in both quantity and quality for the various facilities necessary for a healthy development of the fishery industry. The improvement of such facilities and also of the transport structure as well as the mechanization of fishing boats and introduction of large boats will contribute towards the increase in production of the fishery products.

5) Forestry products

Production of forestry products in Jakarta is negligible and the demand of forestry products is met from external supply.

6) Industrial products

From the statistical data for Jakarta, it is not possible to obtain the data on the production in weight divided into individual items. The average value of unit weight of each item is therefore calculated from the national average and conversion of the production volume in weight is made from the statistics of production value of the items for Jakarta. As for fuel, an estimation is made from the statistics of volume of the flow into Jakarta via Tanjung Priok. The results are as shown in Table 1-15.

(2) Consumption quantity in Jakarta by commodity items

Due to lack of available data in this regards, the consumption quantity is estimated by the following method.

- 1) The per capital consumption of farm crops and fresh fish are assumed to be the same as the national average.
- 2) The consumption quantity of livestock and dairy products, timbers, food and beverages, textile, apparels and household wares are calculated as a share of national consumption, assuming the same share as the share of GRDP of Jakarta in the national GDP.

Table 1-21 Production and Consumption of Goods in Jakarta, 1973

| | (unit: ton) | | | |
|------------------------------------|-------------|-------------|---------|-----------|
| Goods | Production | Consumption | Surplus | Deficit |
| Farm Food Corps: | | | | |
| Rice | 30,726 | 747,789 | | 717,063 |
| Maize | 143 | 124,553 | | 124,410 |
| Cassava | 8,486 | 394,366 | | 385,880 |
| Sweet potato | 836 | 84,730 | | 83,894 |
| Peanuts | 282 | 9,539 | | 9,257 |
| Soybeans | 0 | 17,929 | | 17,929 |
| Fruits | 60,678 | 159,734 | | 99,056 |
| Vegetables | 110,438 | 84,157 | 26,281 | |
| Potatoes | 2,250 | 6,189 | | 3,939 |
| Estate Crops | 0 | 253,719 | | 253,719 |
| Animal Husbandry: | | | | |
| Livestock slaughtered | 5,966 | 41,863 | | 38,283 |
| Eggs | 3,299 | 11,298 | | 7,999 |
| Fresh milk | 4,080 | 2,559 | 1,521 | |
| Meat | 39,460 | 35,575 | 3,885 | |
| Fishery Products | 9,751 | 45,942 | | 36,191 |
| Forest Products | 0 | 519,164 | | 519,164 |
| Industrial Products: | | | | |
| Food, beverages & tobacco | 313,951 | 587,258 | | 273,307 |
| Textile, clothing, furniture, etc. | 164,082 | 92,421 | 71,661 | |
| Raw materials & auxiliary | 122,884 | 278,940 | | 156,056 |
| Cement | 0 | 236,905 | | 236,905 |
| Other construction materials | 214,277 | 378,651 | | 164,374 |
| Iron & steel products | 28,671 | 60,445 | | 31,774 |
| Fertilizer & pesticides | 44,541 | 5,255 | 39,286 | |
| Fuel | 0 | 1,223,377 | | 1,223,377 |
| Small & household manufacturing | 232,877 | 810,038 | | 577,161 |
| Other manufacturing products | 83,617 | 354,163 | | 270,546 |

Table 1-22 Production and Consumption of Goods by Category in Jakarta, 1973

| | Production | Consumption | Difference |
|--|------------|-------------|------------|
| A. Agricultural Products | 266,644 | 2,368,802 | 2,102,158 |
| 1. Farm Food Crops | 213,839 | 1,954,784 | 1,759,845 |
| 2. Estate Crops | 0 | 304,463 | 304,463 |
| 3. Livestock & its Products | 52,805 | 109,555 | 56,750 |
| B. Fishery Products | 9,751 | 55,130 | 45,379 |
| C. Forest Products | 0 | 622,997 | 622,997 |
| D. Industrial Products | 1,566,369 | 5,235,689 | 3,957,782 |
| 1. Food, Beverages & Tobacco | 408,136 | 763,435 | 355,299 |
| 2. Textile, Clothing, Paper, Furniture & Other Household Wares | 213,307 | 120,147 | 93,160 |
| 3. Raw Materials & Auxiliary | 159,749 | 362,622 | 202,873 |
| 4. Cement | 0 | 307,977 | 307,977 |
| 5. Other Construction Materials | 278,560 | 492,246 | 213,686 |
| 6. Iron & Steel Products | 37,272 | 78,579 | 41,307 |
| 7. Fertilizer & Pesticides | 57,903 | 6,832 | 51,071 |
| 8. Fuel | 0 | 1,590,390 | 1,590,390 |
| 9. Small & Household Manufacturing | 302,740 | 1,053,049 | 750,309 |
| 10. Other Manufacturing Products | 108,702 | 460,412 | 351,710 |

(unit: ton)

- 3) The share by Jakarta of the net production value of manufacturing sector in the national total is made applicable to the national consumption of estate crops products and raw materials and auxiliary as well as to 70% of the national consumption of iron and steel products to obtain the consumption of Jakarta for these items.
- 4) The share by Jakarta of the net production value of construction sector in the national total is made applicable to the national consumption of cement and other construction materials as well as 30% of the national consumption of iron and steel products to obtain the consumption of Jakarta for these items.
- 5) The consumption of fertilizers is estimated from the Jakarta share in net production value of farm food crops in the national total.

The production and consumption quantity by items is as in Table 1-21. In consideration of the disparity between urban and rural areas in production and consumption, an extra 20% for agriculture and forestry products and an additional 30% for industrial products were added for both the production and consumption in Jakarta and the results by category are as shown in Table 1-22.

1-5-4 Modal Distribution of Goods Transport

Goods flow between Jakarta and other regions is handled by ship, rail, air and truck.

(1) Ship transport

The main ports in Jakarta are Tanjung Priok, Sunda Kelapa and Kali Baru. The ports of Sunda Kelapa and Kali Baru are mainly used for inter-insular trade purpose, while international trade is almost entirely handled by Tanjung Priok. The volume of goods handled at the various ports are as follows.

| Ports | 1970 | 1971 | 1972 | 1973 | 1974 |
|--------------|-----------|-----------|-----------|-----------|-----------|
| Tg. Priok | 4,794,973 | 5,045,585 | 5,877,559 | 7,834,432 | 8,447,225 |
| Sunda Kelapa | 524,959 | 566,610 | 652,444 | 793,139 | 733,667 |
| Kali Baru | 91,020 | 58,986 | 75,095 | 112,121 | 124,918 |
| Total | 5,410,952 | 5,671,181 | 6,605,098 | 8,739,692 | 9,305,810 |

Source: Cargo loading and unloading at Ports in Indonesia, 1970-74.

(2) Rail transport

As there were no data available on goods handled by rail in Jakarta, the volume was estimated from the rail goods volume in Java & Madura region and also from reports of past studies.

(3) Air transport

The international and domestic air cargo handled are as shown below, showing that the share by air transport of total goods flow is very small.

Table 1-23 Trends in Air Traffic

(unit: ton)

| | International | | Domestic | | Total |
|------|---------------|---------|-----------|---------|--------|
| | Departure | Arrival | Departure | Arrival | |
| 1969 | 1,266 | 4,672 | 2,433 | 767 | 9,138 |
| 1970 | 1,203 | 8,404 | 2,736 | 937 | 13,280 |
| 1971 | 1,209 | 9,185 | 3,667 | 1,649 | 15,710 |
| 1972 | 1,502 | 7,967 | 5,353 | 2,212 | 17,034 |
| 1973 | 1,806 | 10,097 | 7,867 | 2,462 | 22,232 |
| 1974 | 1,770 | 12,190 | 10,621 | 2,949 | 27,530 |
| 1975 | 2,441 | 13,215 | 13,353 | 3,557 | 32,566 |

Source: Statistical Year Book of Jakarta, 1976.

(4) Truck transport

The volume of goods flow by truck between Jakarta and other regions is estimated from the data of goods flow by truck through Bekasi, Pasas Reko and Kalideres and also from the truck O-D survey by B/M in 1972.

The resultant modal distribution of goods transport is summarized in Table 1-24.

Table 1-24 Modal Distribution of Goods Transport

(x 1,000 ton)

| Year | Vessel | Truck | Air | Rail | Total |
|------|--------|-------|-----|-------|--------|
| 1970 | 5,410 | 3,139 | 13 | 757 | 9,319 |
| 1971 | 5,671 | 4,261 | 16 | 866 | 10,814 |
| 1972 | 6,605 | 6,290 | 17 | 920 | 13,832 |
| 1973 | 8,739 | 8,705 | 22 | 1,034 | 18,500 |
| 1974 | 9,305 | 9,216 | 27 | 954 | 19,502 |

1.6 Existing Traffic Situation and Traffic Survey

1-6-1 Transportation Network in Jakarta

(1) Road network

According to statistics, there were about 1,800 km of roads and streets in use in Jakarta in the year 1975. The road density is quite high in the central business district (CBD) and in such districts as Kebayoran Baru where improvement has been accomplished through urban planning, and the road surface condition is generally good. However, in the other districts, the density of road is low, and except for the main trunk roads, the road surface condition is poor. The network pattern in Jakarta is such that the CBD is with a grid pattern whereby over ten roads extend radially from the center to the peripheral areas. The Jl. Let Jen S. Parman - Jl. Jendral Gatot Subroto, which runs in a circular direction at about 4 km from the urban centre, is the only ring linking these radial roads, so that the traffic congestion along the radial roads is conspicuous. This network may be said to serve the existing urban activities of Jakarta in a center-concentrated pattern.

(2) Railroad network

The railroad may be grouped into a circular route encompassing the CBD, four radial routes extending to the rural area and a route connecting CBD and Tanjung Priok. At present, the railroad does not serve as a means of intra urban transportation but rather has the characteristics of an inter-regional transport route.

(3) Port

The ports in the city of Jakarta are the international port of Tg. Priok and the domestic ports of Kalibaru and Sunda Kelapa. The former is a commercial and industrial port whereas the two latter are more of fishery ports in characteristics.

(4) Airport

The Halim International Airport is situated at about 12 km to the southeast of the CBD of Jakarta, and there is another Kebayoran Airport 3 km away for domestic use. The airports

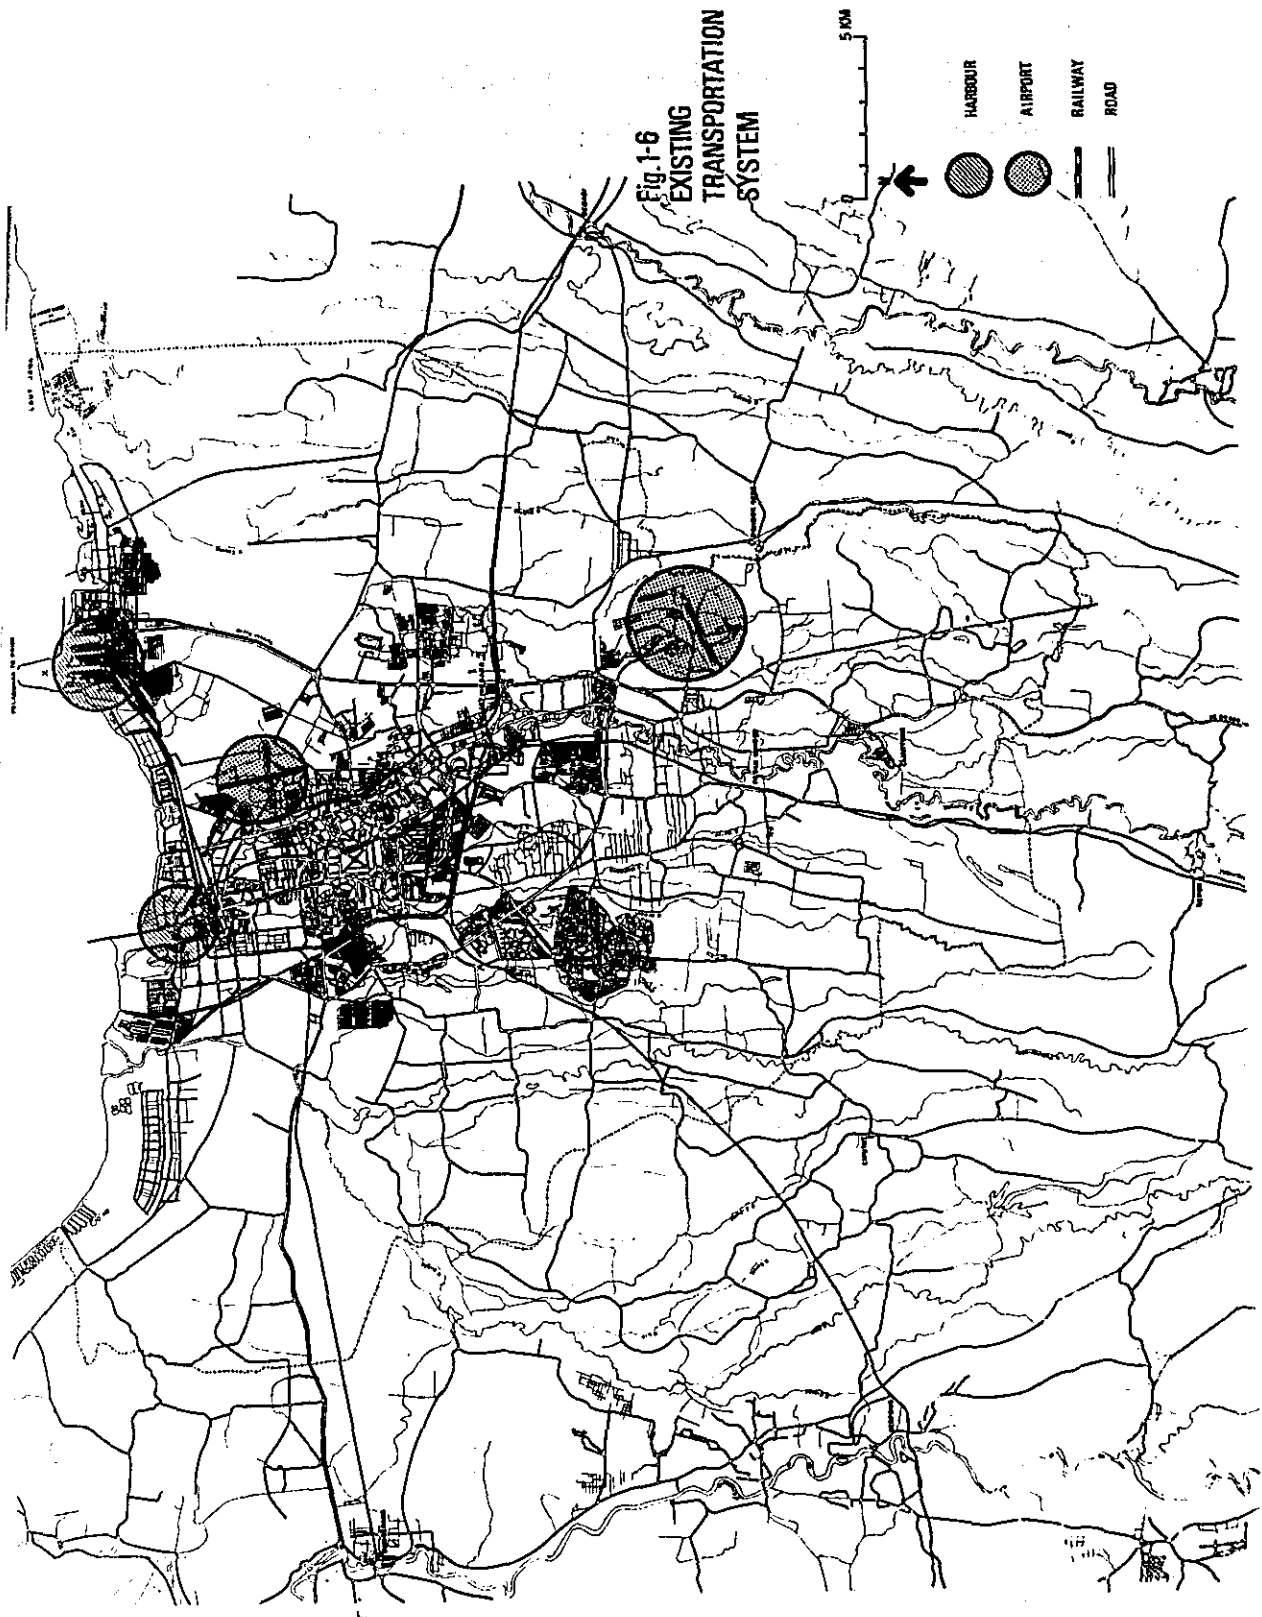

Fig. 1-6
EXISTING
TRANSPORTATION
SYSTEM

HARBOUR
AIRPORT
RAILWAY
ROAD

5 KM

serve as connecting points for road and air transport. In future, another new international airport is planned to the West of Jakarta at about 20 km from CBD.

1-6-2 Traffic Volume by Mode of Transport

The traffic volumes of both goods and passengers by modes of transport in Jakarta for the year 1975 are as shown in Table 1-25. (This figures of ports are for 1974)

Goods transport were mainly handled by sea and by air. For air cargo, there was an excess of inflow volume for international traffic and an excess in outflow for domestic traffic, and it can be deducted that there was considerable transfer at the airport. Tg. Priok handled over 90% of cargo by sea transport.

Table 1-25 Traffic Situation in Jakarta

| TRUCK | Incoming goods | Outgoing goods | Total |
|-----------------------|----------------|----------------|-------|
| Thousand ton per year | 3,259 | 1,304 | 4,563 |

| TRAIN | Passengers within the city | Passengers outside the city | Total |
|--------------------------|----------------------------|-----------------------------|-------|
| Thousand person per year | 197 | 2,955 | 3,152 |

| PASSENGER VIA JAKARTA AIRPORT | International | Domestic | Total |
|-------------------------------|---------------|----------|-------|
| Thousand person per year | 907 | 1,710 | 2,617 |

| AIR CARGO VIA JAKARTA AIRPORT | International | | | Domestic | | | Total |
|-------------------------------|---------------|---------|--------|-----------|---------|--------|--------|
| | Departure | Arrival | Total | Departure | Arrival | Total | |
| Thousand ton per year | 2,441 | 13,215 | 15,656 | 13,353 | 3,557 | 16,910 | 32,566 |

(thousand ton per year)

| CARGO LOADED AND UNLOADED AT PORTS | International | | | Inter Island | | | Total |
|--|---------------|--------|-------|--------------|--------|-------|-------|
| | Unloaded | Loaded | Total | Unloaded | Loaded | Total | |
| Tg. Priok | 4,477 | 155 | 4,632 | 3,374 | 440 | 3,814 | 8,446 |
| Sunda Kelapa | - | - | - | 517 | 217 | 734 | 734 |
| Kali Baru | - | - | - | 114 | 11 | 125 | 125 |

1-6-3 Existing Cross Section Traffic Volume of Roads

The traffic volumes of main road sections in Jakarta for the year 1976 are as shown in Table 1-26. From the table it is seen that the average peak ratio was 8% and average daytime ratio was 1.36. Due to a shortage of road compared to traffic demand, during the 12 hour daytime period, especially the hours before and after the peak period, considering congestion occurred. 40% of the location had the peak hours concentrated at the 7:00 to 9:00 a.m. and 20% of the locations had peak hours at 4:00 to 6:00 p.m., due mainly to the commuting traffic.

For the traffic situation at the peripheral areas, 12-hour traffic survey from 6:00 a.m. to 6:00 p.m., were carried out in April, 1977, for 6 vehicle types at 11 locations which are the junctions of the Ring Road and other main roads for the purpose of the study, and the results are as shown in Table 1-27 and Table 1-28. From the results, it is noted that 85,000 vehicles crossed the proposed Ring Road in 12 hours and the average peak ratio against 12 hours traffic volume for all locations was 9.6% which is considerably lower than the corresponding peak ratio of 11% for the urban center. However, this is the average of traffic in both directions and in the morning hours) came to 12.5% indicating the high rate of inflow from the periphery. The average heavy vehicle ratio for all 11 locations was 25% which is higher than the ratio in the urban center.

The trend of traffic volume change outside the Jakarta city is as shown in Table 1-29 and Fig. 1-8. It is seen that for all direction, the traffic volume increased drastically after 1974, the increase being particularly conspicuous in the southern

Table 1-26 Traffic Volume in DKI Jakarta

1-6-4 Existing Situation of Travel Speed

A travel speed survey was conducted for the roads in Jakarta to understand the travel speed of the road sections of the existing road network, the state of congestion, the situation of vehicle stopping and restarting, and the reasons for the survey was in the following process.

- (1) A passenger car was made to travel along the road section under survey and the distance between check points (usually the major junctions) was recorded from the speedmeter in

Fig. 1 - 8 NUMBER OF VEHICLES PER DAY BY DIRECTION

the vehicle while the travel time between check points were recorded by stopwatches.

- (2) If the vehicle is forced to stop along the route, the duration of stopping was recorded by stopwatches and the reason for stopping noted.

The travel speed survey was carried out for a 6 day period from 14 to 19 April, 1977 and the results are as in Table 1-30 and Table 1-31 and Fig. 1-9.

From the survey, it was noted that the average travel speed for all road sections was 32.8/km which is quite high, considering the existing traffic condition in the urban center. This is due to the fact that travelling conditions are more favorable on the peripheral road, particularly the new roads of higher standard (such as Jl Komodor Yos Sudarso, etc.).

As for stopping time, the traffic signal and traffic congestion are the major causes for stopping in the main trunk road in the urban area, whereas for minor streets, especially those with two traffic lanes, the interference by right-turning vehicles and by stopping of buses are the main causes.

Table 1-30 Distribution of Travel Speed

| <u>Travel speed</u> | <u>Percentage</u> |

| 5. Interference by right-turning car : | 97 sec, (2.4%), 10 times |
| 6. Congregation along road : | 56 sec, (1.4%), 4 times |
| 7. Bus stopping : | 53 sec, (1.3%), 8 times |
| 8. Others : | 38 sec, (0.9%), 5 times |
| Average travel speed : | 32.8 km/hour |

1.7 Existing Landuse Situation

1-7-1 Overall

The total area of Jakarta in 1976 was about 65,000 ha and the landuse pattern is of the center core pattern centering around the old urban center.

The development of the business and commercial area runs longitudinally along the north-south axis, and residential district, development is mainly in the south and southwest directions.

The distribution of land use in area is obtained from the land use map (1:20,000 in scale) of 1973 as follows:

Table 1-32 Landuse in Jakarta, 1973

| | Area (ha) | % |
|---|-----------|-------|
| Residential Area | 18,324 | 28.0 |
| Administrative, commercial and Business Area | 1,396 | 2.1 |
| Industrial Area | 1,033 | 1.6 |
| Public Facilities excluding Administrative Area | 570 | 0.9 |
| Agriculture & Green Area | 44,168 | 67.4 |
| Total | 65,490 | 100.0 |

Source: Landuse map of Jakarta, 1973 (scale = 1:20,000)

The landuse distribution in 1972 is as follows:

Table 1-33 Landuse in Jakarta, 1972

| | Area (ha) | % |
|----------------------------------|-----------|------|
| Illegally occupied land | 9,097 | 27.4 |
| Legal residential area | 6,339 | |
| Industrial area | 910 | 1.9 |
| Indivisual service industry area | 180 | |
| Commercial area | 734 | 1.3 |
| Agricultural area | 27,767 | 49.3 |
| Land for infrastructure | 8,521 | 69.4 |
| Recreation area | 984 | 20.1 |
| Unused land | 1,830 | |
| Total | 56,362 | |

Source: JMATS

The population of Jakarta by district (Wilaya) and the population density are as shown in Table 1-34. The population varies greatly from district to district, and the central (Pusat) district is with an extremely high density of 286 persons/ha.

The population in Bo-Ta-Bek area and the population density are as shown in Table 1-35, showing that the density is very low compared with Jakarta, indicating that there is further ground for development.

Table 1-34 Population Density in Jakarta, 1975

| District | Area (ha) | Population (in 1,000) | Density (person/ha) |
|-----------------|-----------|-----------------------|---------------------|
| Pusat (Central) | 4,955 | 1,419.6 | 286 |
| Utara (North) | 13,748 | 715.4 | 52 |
| Barat (West) | 13,124 | 1,011.9 | 77 |
| Timur (East) | 19,096 | 1,031.5 | 54 |
| Selatan (South) | 14,568 | 1,298.3 | 89 |
| Total | 65,490 | 5,476.0 | 83.6 |

Table 1-35 Population Density of Bo-Ta-Bek Area, 1975

| Region | Area (ha) | Population (in 1,000) | Density (person/ha) |
|-----------|-----------|-----------------------|---------------------|
| Bogor | 328,689 | 2,022 | 6.2 |
| Tangerang | 134,627 | 1,155 | 8.6 |
| Bekasi | 147,252 | 897 | 6.1 |
| Total | 610,568 | 4,074 | 6.7 |

1-7-2 Residential Area

In Jakarta, about 10% of the population is residing in the residential area constructed by the Dutch (high class residential area) during the colonial days, such as Kebayoran Baru Area, and followed up with planned development after the war. The Kebayoran Baru area, covered with green vegetations, is a very favorable tropical residential area for Jakarta, and the population density was 136 persons/ha in 1976.

On the other hand, 50% of the population are living in Kampung where urban facilities are not well provided or squatter areas

Fig. 1-10
D.K.I. JAKARTA
LAND USE, 1973

0 5 KM

-  COMMERCIAL, BUSINESS & INSTITUTIONAL AREA
-  INDUSTRIAL AREA
-  RESIDENTIAL AREA
-  GREEN ZONE

where the density is high and the sanitary condition is very poor, so that on the whole housing condition in Jakarta may be said to be very poor. In 1976, the total area of Kampung was 5,700 ha with a population of 2.4 million so that the population density in Kampung averaged 418 persons/ha.

The reddish brown volcanic clay that extends over Jakarta is the material for making bricks and tiles, providing very cheap construction materials. In the urban centers most of the buildings are brick laid single layer houses covered with undecorated tiles. The construction cost increases rapidly with the increase in number of stories of the houses so that the unit cost of a four stories flat is double that of a single stories houses. Due to the land cost being comparatively cheap, flats are not commonly found in Jakarta, but it is anticipated that together with the future rise in land cost, more flats will be constructed.

In the Kampung and the squatter area, the government is now making effort to provide local streets, drains schools, etc., through the Kampung program. For the poverty stratum of the population, core housing units (skeleton unit with columns, roof and toilet only) are provided for sale together with land both by the government and private developers.

For the low income stratum population, low cost housing units are constructed and sold by the government and private developers. In Depok area, a large scale low cost housing estate is under development.

For the middle and high income strata, typical housing units and high class houses are developed by private developers.

The standard living space is planned at 9m²/person by the national government to 12m²/person by the Jakarta municipality. Since the average household is of 5 persons, an average housing is therefore about 45 - 60 m².

For reference purpose, it is noted that the target standard for 1988 for a typical household of 4 persons in Japan is planned at 50 m² as a minimum and 86 m² as the average.

Fig. 1-11
LOCATION OF
KAMPUNGS, 1975

1-7-3 Commercial and Business Area

The commercial and business area of Jakarta is concentrated around the Independence Monument. Therefore during the rush hours in the morning and evening many vehicles crowd on the intersection of the two north-to-south trunk roads on both sides of the independence memorial plaza, namely, J. Thamrin and Jl. Gajahmada with Jl. Pasar and Jl. Gunung Sahari, often causing traffic congestion.

There are not 32 activity centers in Jakarta, and the total area of the commercial and business area is about 1,600 ha.

1-7-4 Industrial Area

As seen from Fig. 1-10, the industrial areas in Jakarta are quite evenly distributed over the city. The industrial zones as planned in the masterplan for Jakarta area as follows:

(1) Pulogadung district

The industrial area of Jakarta starts from here due to its connection with the port, and all types of industries are allowed. The employed labour in this district is planned to occupy one-tenth of the entire employed industrial labour of Jakarta.

(2) Cilincing district

Goods processing industry will be allowed in this district.

(3) Ancol district

This is planned as a goods assembly factory zone.

(4) Pluit district

Assembly factory and electronic factory area.

(5) Along Jakarta - Tangerang Highway

Dirty factories are concentrated here.

(6) Along Jakarta - Serpong Railway (Pal. Merah)

It is planned that the family industry for batik now located in the city center will be moved to here.

(7) Along the highway to Bogor (Gandaria) Since factory waste from here will greatly affect Jakarta, it is planned that only clean factories are allocated here.

Assuming that of the total employed labor in the secondary industry in 1976, 60% were in the manufacturing industry, then the density of labor employed in factories would be about 140 employees/ha.

Table 1-36 Distribution of Factories in Jakarta (1975)

| <u>District</u> | <u>%</u> |
|-----------------|------------|
| Utara | 14 |
| Barat | 19 |
| Timur | 22 |
| Pusat | 21 |
| Selatan | 24 |
| <u>Total</u> | <u>100</u> |

1-7-5 Recreation Area

According to JMATS, the total park area in Jakarta was 1974 ha in 1972, or an average of 2m²/person.

The following are the three large parks developed.

(1) Ancol Park (Sea-side park)

(2) The zoo

Situated in Kandang district towards the southwest of the junction between Jakarta - Depok Railway and the Ring Road.

(3) Taman mini park

Situated towards the northeast of the junction between Jagorawi Highway and the Ring Road.

1-7-6 Various Terminal Facilities

The locations of existing and planned taxi and bus terminals are as shown in Fig. 1-11, whereas the wholesale markets are as follows:

- (1) Pasas Minggu : Agricultural products market
- (2) Kuramat Jati : Agricultural products market
- (3) Cengkareng : Agricultural products market (planned)
- (4) Cipinang : Rice market
- (5) Cakung : Construction materials market (planned)

CHAPTER 2 LAND USE PLAN

2.1 Review of reports available from the aspect of DKI Jakarta Land Use

In reports which deal with the land use of DKI Jakarta, those listed below are going to be reviewed, here. They are:

- 'The Master Plan of DKI Jakarta, 1965-1985,' 1966;
- 'Jakarta Metropolitan Area Transportation Study,' 1975; and
- 'JABOTABEK,' 1973, 1975.

2-1-1 'The Master Plan of DKI Jakarta, 1965-1985,' 1966

The 'Master Plan' in this report was made in 1965 on the assumption of the future population of 6.5 millions in 1985. Characteristics about its land use concept can be summarized as follows:

- concentration of population on the central part of DKI Jakarta;
- less reliance on the public transportation system than the private transportation system;
- clear separation of residential areas from work places;
- a compact CBD without dispersion of sub-centers around;
- a 3 to 4 KM wide green belt 15 KM away from the CBD to be a recreation zone;
- an industrial area with large scale industries on the east of the CBD extending towards the further east in future; and
- grid street pattern of ring and radial roads.

Table 2-1 Land Use in 'The Master Plan of DKI Jakarta, 1965-1985'

| | Area (ha) | % |
|------------------|-----------|-------|
| Residential | 25,543 | 40.5 |
| Retails & Office | 3,065 | 4.7 |
| Industry | 6,745 | 10.3 |
| Institutional | 867 | 1.3 |
| Green | 28,270 | 43.2 |
| Total | 65,430 | 100.0 |

2-1-2 'Jakarta Metropolitan Area Transportation Study,' 1975

Those assumptions on which 'The Master Plan of DKI Jakarta, 1965-1985' was made have been outdated by the overwhelming population concentration onto DKI Jakarta.

Fig. 2-1 Methodological Flow Chart of Population Forecast, Land Use Planning, Employment Situation Forecast, etc.

Notes:

Ja.: Jakarta
Bo.: Bogor+Tangerang+Bekas

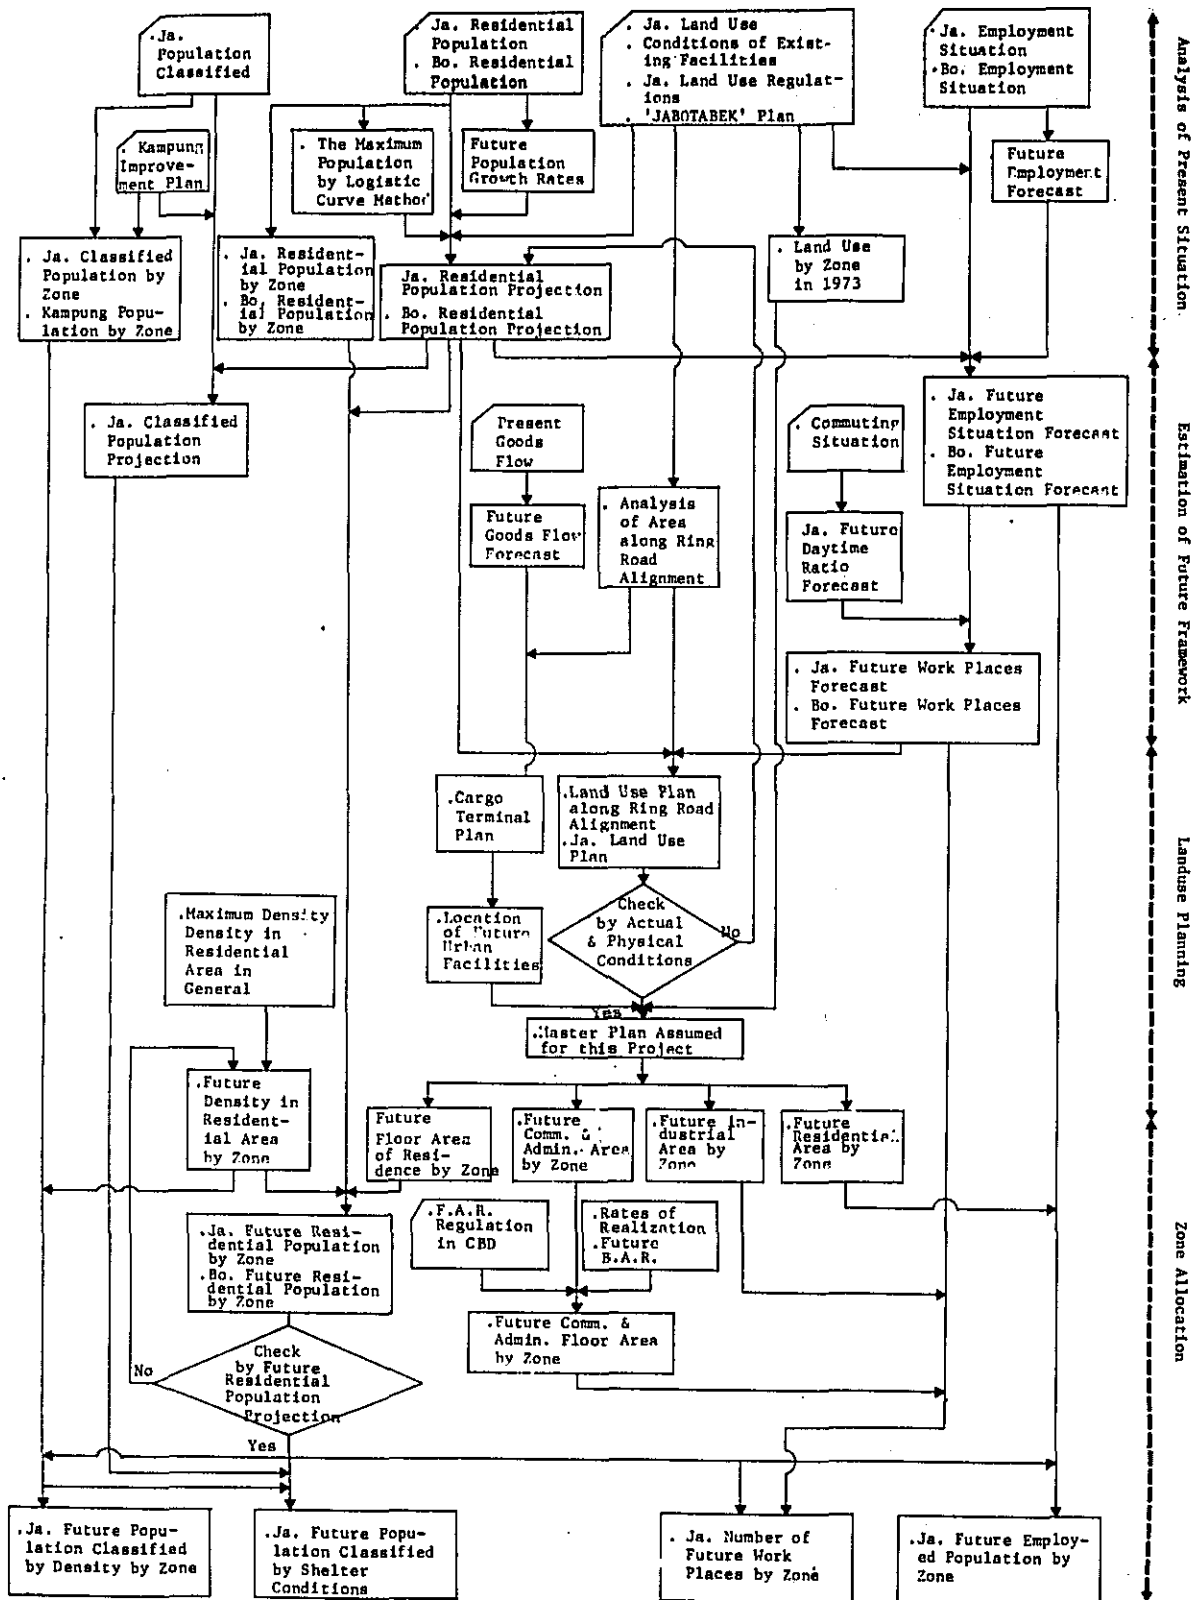

Fig. 2-2
 REVISED MASTER PLAN,
 D.K.I. JAKARTA
 1965 - 1985

'Jakarta Metropolitan Area Transportation Study' proposes the 'Adjusted Master Plan' based on radically different land use concept, and then, made a comparison with the 'Master Plan' from various economic aspects.

Characteristics about the land use concept of the 'Adjusted Master Plan' can be summarized as follows:

- several urbanized sub-centers on the periphery of DKI Jakarta; and
- developing residential areas along radial highways deep into the surrounding green areas.

By combining those mentioned above, several advantages are generated, and they are:

- easy access to work places from residential areas because both of them are located along highways;
- neighbouring of radially separated residential areas by introducing recreational areas in between; and
- easy goods supply to residential areas through commercial areas along major highways.

The comparison between the 'Adjusted Master Plan' and the 'Master Plan' suggests the superiority of the former in many ways. The report proposes the 'Improved Master Plan' based on the findings in the process of comparing. In the 'Improved Master Plan' the capacity of population absorption by the CBD has been improved by its organized mastertransportation system.

2-1-3 'JABOTABEK,' 1973, 1975

The 'JABOTABEK' report deals with the wider region surrounding DKI Jakarta aiming at dispersion of urban facilities over the hinterland. The area dealt with is conventionally called the JaBoTaBek region including Kabupatans of Bogor, Tangerang and Bekasi, and also, DKI Jakarta.

As alternative development patterns the 'Concentric Pattern' and the 'Linear Pattern' are studied.

(1) Concentric Pattern

The semi-circular link of sub-centers along the periphery of DKI Jakarta is proposed.

Disadvantages of this pattern are:

- Different links among sub-centers from those connecting sub-centers and the CBD have to be developed; and
- In developing the area around sub-centers independently the balanced development of the integrated JaBoTaBek region might not be preserved.

(2) Linear Pattern

The development is focused on the three radial areas on the axis between Bogor, Tangerang and Bekasi, and DKI Jakarta.

Advantages of this pattern are:

- Existing facilities are mostly utilized; and
- As the potential population absorber the area along the Serpong - D.K.I. Jakarta axis on which only a railway truck runs at present can be developed.

From the two patterns mentioned above the 'Linear Pattern' which has the larger capacity of population absorption with an economical development has been adopted, and then, the capacity of its population absorption is compared with the future JaBoTaBek population forecasted.

As a result, it has become clear that D.K.I. Jakarta cannot even meet the amount of its natural population increase, while it is possible for the whole JaBoTaBek region to absorb it.

When the increase by migration is taken into account, the absorption capacity of the JaBoTaBek region will be far smaller than the total future population.

Then, based upon above analyses, various methods of population control are proposed.

2.2 Forecast of Population and Employment

2-2-1 Forecast of Future Population

(1) Indonesia and Java/Madura

The annual population growth rate of Indonesia in 1975 was 2.4% and that of Java/Madura was 2.2%. The effect of the 'Family Planning' campaign will become visible gradually. Therefore, it would be reasonable to assume that the population growth rate of Indonesia would decline to around 1.7% and that of Java/Madura to 1.6% in the year 2000. Then, the future population would be as shown in Table 2-2 and Table 2-3.

Table 2-3 Population Forecast in Java/Madura

| | Population (x 1,000,000) | Annual Growth Rates (%) | Average Annual Growth Rates (%) |

Fig. 2-4 POPULATION GROWTH RATES IN INDONESIA

Fig. 2-5 POPULATION GROWTH RATES IN JAVA / MADURA

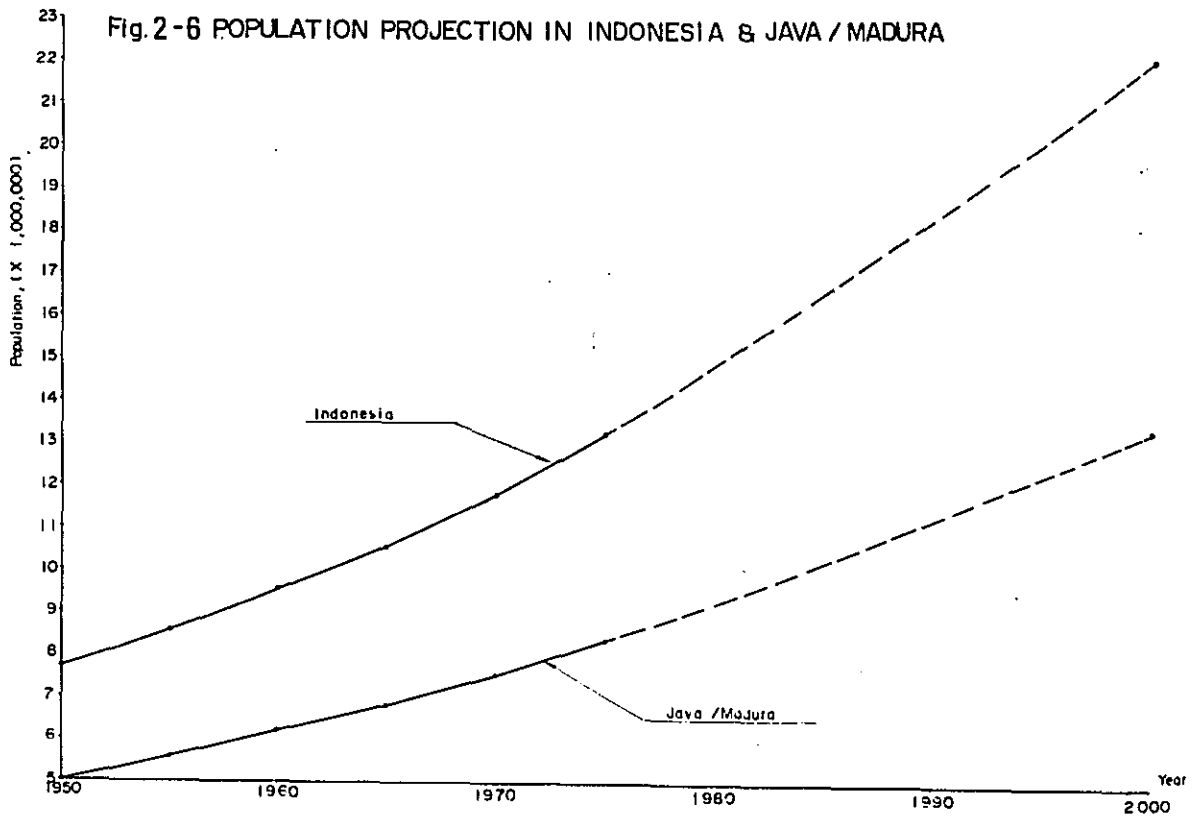

Fig. 2-6 POPULATION PROJECTION IN INDONESIA & JAVA / MADURA

(2) DKI Jakarta

The population forecast in DKI Jakarta is done through two steps as in Fig. 2-1. They are estimation of the maximum population by the logistic curve projection method and population forecast by growth rates.

- 1) Estimation of the maximum population of DKI Jakarta by the logistic curve projection method.

A logistic curve is defined as follows:

$$y = \frac{K}{1 + me^{-at}}$$

where, y = population

t = time

a = gradient of the curve

m = coefficient determining of the curve

k = coefficient showing the maximum population

By differentiating the above equation by t, the following equation can be obtained.

$$\frac{dy}{dt} = ay - \frac{a}{ky}^2$$

This indicates that the note of population growth is proportional to the population at that moment in the course of population development, and also, that it receives a resistance which is proportional to a square of the population.

In calculating the real number of K being the maximum population, populations of DKI Jakarta in the past are used and the maximum population of DKI Jakarta is forecasted to be $10,690 \times 10^3$ persons.

- 2) Population forecast in DKI Jakarta by growth rates
The annual population growth rate of DKI Jakarta was 4.3% in 1975 of which the growth rate of natural increase was 2.0% and the rest was the growth rate of migration.

Fig. 2-7 THE MAXIMUM POPULATION OF D.K.I. JAKARTA, [K], PROJECTED BY LOGISTIC CURVE TRANSFORMATION

Due to the effect of the 'Family Planning' campaign the growth rate of natural increase can be supposed to decline gradually. We assume it would become about 1.5% in the year 2000.

The migration into DKI Jakarta would also decline, if the 'Trans-Migration Policy' by the government is successfully carried out. So, we assume 0% migration growth rate in the year 2000, as shown in Fig. 2-7. The upper and the lower curves indicate the case of the % growth rate in 2010 and 1990.

The population projection in DKI Jakarta in Fig. 2-8 is based on the above assumptions of three different growth rates curves.

Our projection is much steeper than that of 'The Master Plan of DKI Jakarta, 1965-1985' and it is fairly close to 'JMATS' projection. Expecting different growth rates at each point on the course of population growth, our projection has a sort of convex shape while assuming the same population as 'JMATS' in the year 2000.

3) BoTaBek area

The annual population growth rate of the BoTaBek area was about 2.2% in 1975, and a large part of it was the natural increase. The natural increase would decline as in the case of DKI Jakarta, and it is assumed to become around 1.5% in the year 2000.

As the development of the BoTaBek area proceeds and the capacity of population absorption by DKI Jakarta approaches its limit, the migration into the BoTaBek area from other parts of DKI Jakarta, and also, a sort of trans-migration from DKI Jakarta would increase steadily. In Fig. 2-11 the maximum projection is the case of the 0% growth rate of migration in 2020, the medium is in 2010 and the minimum is in the year 2000.

Fig. 2-8 ANNUAL POPULATION GROWTH RATES D.K.I. JAKARTA

Fig. 2-9 POPULATION PROJECTION IN D.K.I. JAKARTA

Consequently, the future population in the BoTaBek area would be as shown in Table 2-6. Population projection of this study in the BoTaBek area is steeper than the 'JMATS' projection but not so than the 'West Java Tollway System Study' projection.

a) Forecasted by West Java Tollway System Study

| | (x 1,000) | | | |
|------|--------------|------------------|---------------|--------------|
| | <u>Bogor</u> | <u>Tangerang</u> | <u>Bekasi</u> | <u>Total</u> |
| 1985 | 2,910 | 1,645 | 1,391 | 5,946 |

b) Forecasted by JMATS

| | (x 1,000) | | |
|---------|-------------|-------------|-------------|
| | <u>1985</u> | <u>1990</u> | <u>2000</u> |
| BoTaBek | 5,490 | 6,050 | 7,250 |

4) JaBoTaBek area

By adding the future population of DKI Jakarta and that of the BoTaBek area, that of the JaBoTaBek region as a whole can be obtained to be about 19.1 millions.

The annual growth rates of the JaBoTaBek area population would decline after 1980 due to the earlier drop of the DKI Jakarta population growth rates.

In comparing the projection of this study to that of the 'JABOTABEK' report, it has to be taken into account that the JaBoTaBek area in the 'JABOTABEK' report includes the wider hillside area which is out of the boundary of this study.

| | JABOTABEK Area by the Report | (million persons) THIS STUDY |
|------|---------------------------------|---------------------------------|
| 1971 | 7.0 | 8.3 |
| 1985 | 12.1 | 13.2 |
| 2000 | 18.3 | 19.1 |

Table 2-4 Population Forecast in D.K.I. Jakarta

| | Maximum | | Medium | | Minimum | |
|------|--|----------------------|--|----------------------|--|----------------------|
| | Average Annual Growth Rates for 5 years. | Population (x 1,000) | Average Annual Growth Rates for 5 years. | Population (x 1,000) | Average Annual Growth Rates for 5 years. | Population (x 1,000) |
| 1975 | 4.0 | 5,410 | 4.0 | 5,410 | 4.0 | 5,410 |

2-2-2 Classified Population

The number of people without permanent address was 11.0% of the total population in 1975. It is unrealistic to predict that this will be less than 5% in the year 2000. These people will be a part of population classified into Temporary by their shelter conditions.

At present, the population in Kampung is about 2.4 millions and its average growth rate is about 1.3%. Therefore, it will be 3.3 millions, or 31% of the total DKI Jakarta population in the year 2000.

Assuming that 80% of the Kampung population would be Semi-Permanent and 20% of it would be Permanent, the Semi-Permanent population will be 25% of the total, and that of Permanent will be 70% in the year 2000.

| 2000 | 70.00 | 25.00 | 5.00 |

2-2-3 Forecast of Employed Population

(1) Rate of employment

a) DKI Jakarta

The rate of employment in DKI Jakarta was 25.8% in 1971. It is assumed to be 31.0% in the year 2000, due to the larger economically active population and the improvement of economic situations.

b) BoTaBek area

The rate of employment in the BoTaBek area was 20.3% 1971. In the year 2000, it would be considerably lower than in DKI Jakarta, due to the lower rate of its economically active population, and it is assumed to be 28%.

(2) Rate of employment by sector

The rate of employment by sector in the year 2000, can be figured out from the area of various kinds of land uses. However, the BoTaBek area dealt with in this report includes the wider hillside area than that in the 'JABOTABEK' report. This is the reason of the higher rate of employment in Sector I, 8.0%, than that of the 'JABOTABEK' report, 5.0%.

2-2-4 Work Places

The commuting population into the JaBoTaBek region from outside is negligible. Therefore, in the whole JaBoTaBek region the

|--------------|------|------|------|-------|-------|-------|
| - Sector I | 326 | 334 | 351 | 412 | 448 | 457 |
| - Sector II | 99 | 118 | 142 | 277 | 398 | 717 |
| - Sector III | 273 | 279 | 294 | 380 | 481 | 705 |
| Total: | 698 | 731 | 787 | 1,069 | 1,372 | 1,379 |

number of work places is considered to be that of employed population. According to the traffic survey in May, 1977, the commuting population from the BoTaBek area into DKI Jakarta was about 110,000 and it is about 2.0% of the total DKI Jakarta daytime population.

In the year, 2000, the increase of the daytime population in DKI Jakarta by commuting is assumed to be about 5.0%, due to the improved Traffic System.

The Sector II employees are in most cases reside close to industrial areas, and so, the ratio of commuting population between in Sector II and Sector III is assumed to be about 1:9.

Taking those commuting population into account, the number of work places in DKI Jakarta by sector would be as shown in Table 2-13.

Fig. 2-15 LAND USE CONCEPT

2.3 Land Use Planning along the Ring Road Alignment

2-3-1 Land Use Planning in DKI Jakarta

According to the doctrine of the 'Modern Urban Design Movement' which has been so popular almost all over the world since the last war, the field of the whole human activities is divided into several major types with their special facilities in the process of design.

Therefore, it should be tried to generate communities of a proper size with not only residential facilities, but also, with work places of commercial and institutional facilities. In the 'Master Plan of DKI Jakarta, 1965-1985' a large industrial area is proposed on the east of the CBD, but it would be also reasonable to blend smaller industrial facilities into residential areas, as long as they do not cause environmental problems. It is also reasonable to disperse medium size commercial and administration areas outside of the CBD creating a chain of sub-centers easily accessible from residential areas. Accessible green areas, even if they are rather small, evenly distributed over a residential areas would be very beneficial for up-grading of their living conditions when the tropical climate of Indonesia is taken into consideration.

2-3-2 Functions of the Ring Road

The alignment of the Jakarta Ring Road we are proposing is about 12 to 15 km from the CBD. When the population of DKI Jakarta exceeds 10 millions, the residential area will extends into the area further than 20 km from the CBD. Therefore, the land use planning along the alignment should fully reflect the above situation, and at the same time, the design of the Ring Road will be affected by it.

The functions of the Ring Road from the aspect of the land use planning are as follows:

- 1) The traffic flow incoming to and outgoing from DKI Jakarta is at present largely concentrated on the few radial highways

causing congestions at several junctions. The Ring Road with interchanges will help to make this traffic flow more multi-directional.

- ii) A portion of the congested CBD traffic is the through-traffic, and the Ring Road would remove it considerably by allowing by-passing giving the land use of CBD more freedom, and also, making the peripheral area of DKI Jakarta more integrated.
- iii) The supply of goods into DKI Jakarta is done almost evenly from all three major directions, while the place of consumption depends on specific commodities. The location of cargo terminals near inter-changes would give some effect on the layout of the place of consumption, namely industrial and commercial areas in DKI Jakarta.
- iv) As mentioned earlier, to improve the capacity of population absorption is essential in land use planning when the massive population increase in future is taken into consideration. The Ring Road will integrate the functions of facilities along its alignment creating larger capacity of population absorption.

2-3-3 Analysis of the Area along the Alignment

As a base of realization of those functions of the Ring Road mentioned in the previous section, the existing conditions of the area along the Ring Road are going to be analyzed, here. The analysis can be itemized as follows:

- a) Soil conditions and topography
By Maps of Soil Conditions and Topography of the area along the alignment, and also, by the information collected during the field survey, the physical conditions of the site are analyzed.
- b) Present land use and development in near future
By aero-photos (Scale: 1/5000) and the field survey the actual land use and the condition of facilities are analyzed.

The authorized land use plan is studied to envisage the situation in near future.

c. Land use regulation and future traffic conditions

By the 'Master Plan' (Scale: 1/20,000) and the Land Use Regulation Map' the future traffic conditions are studied.

Next, by dividing the whole alignment into ten portions as shown in Table 2-14, the appropriate land use of the area around each portion is studied as tabulated in Table 2-15.

Table 2-15 Division of Alignment

| No. | Location of Junction with the Ring Road | Section |
|-----|---|---------|
| 1 | Jakarta Murak Highway | I |
| 2 | Proposed Jakarta Serpong Highway | |
| 3 | Jakarta Serpong Railway | II |
| 4 | Krukut River | III. |
| 5 | Jakarta Bandung Railway | IV |
| 6 | Existing Bogor Highway | V |
| 7 | Jagorawi Highway | VI |
| 8 | Sunter River | VII |
| 9 | Jakarta Cikampek Highway | VIII |
| 10 | Jakarta Surabaya Railway | IX |
| 11 | End of Ring Road | X |

The area assigned for industrial use in the 'Master Plan' is also reasonable by our judgement. It is suggested to distribute industrial areas along the alignment without concentrating onto Pulogadung area only.

The areas suitable for commercial and/or administration uses are the south of Pondok Indah and Pasar Minggu. The improvement of the Jakarta-Bogor Railway would contribute to the development around Pasar Minggu.

The area around the junctions of the extension of the Ring Road and the Tangerang Highway, and also, that of the Ring Road and the Bekasi-Highway would be also suitable for commercial and/or administration uses.

Table 2-16 Suitable Land Use by Section

| Section | Topography | Transportation Condition | Land Use Present & Near Future | Present Land Use Regulation | Suitable Land Use | |
|----------------------|-------------------------|-------------------------------------|--------------------------------|-----------------------------|--------------------------|--|

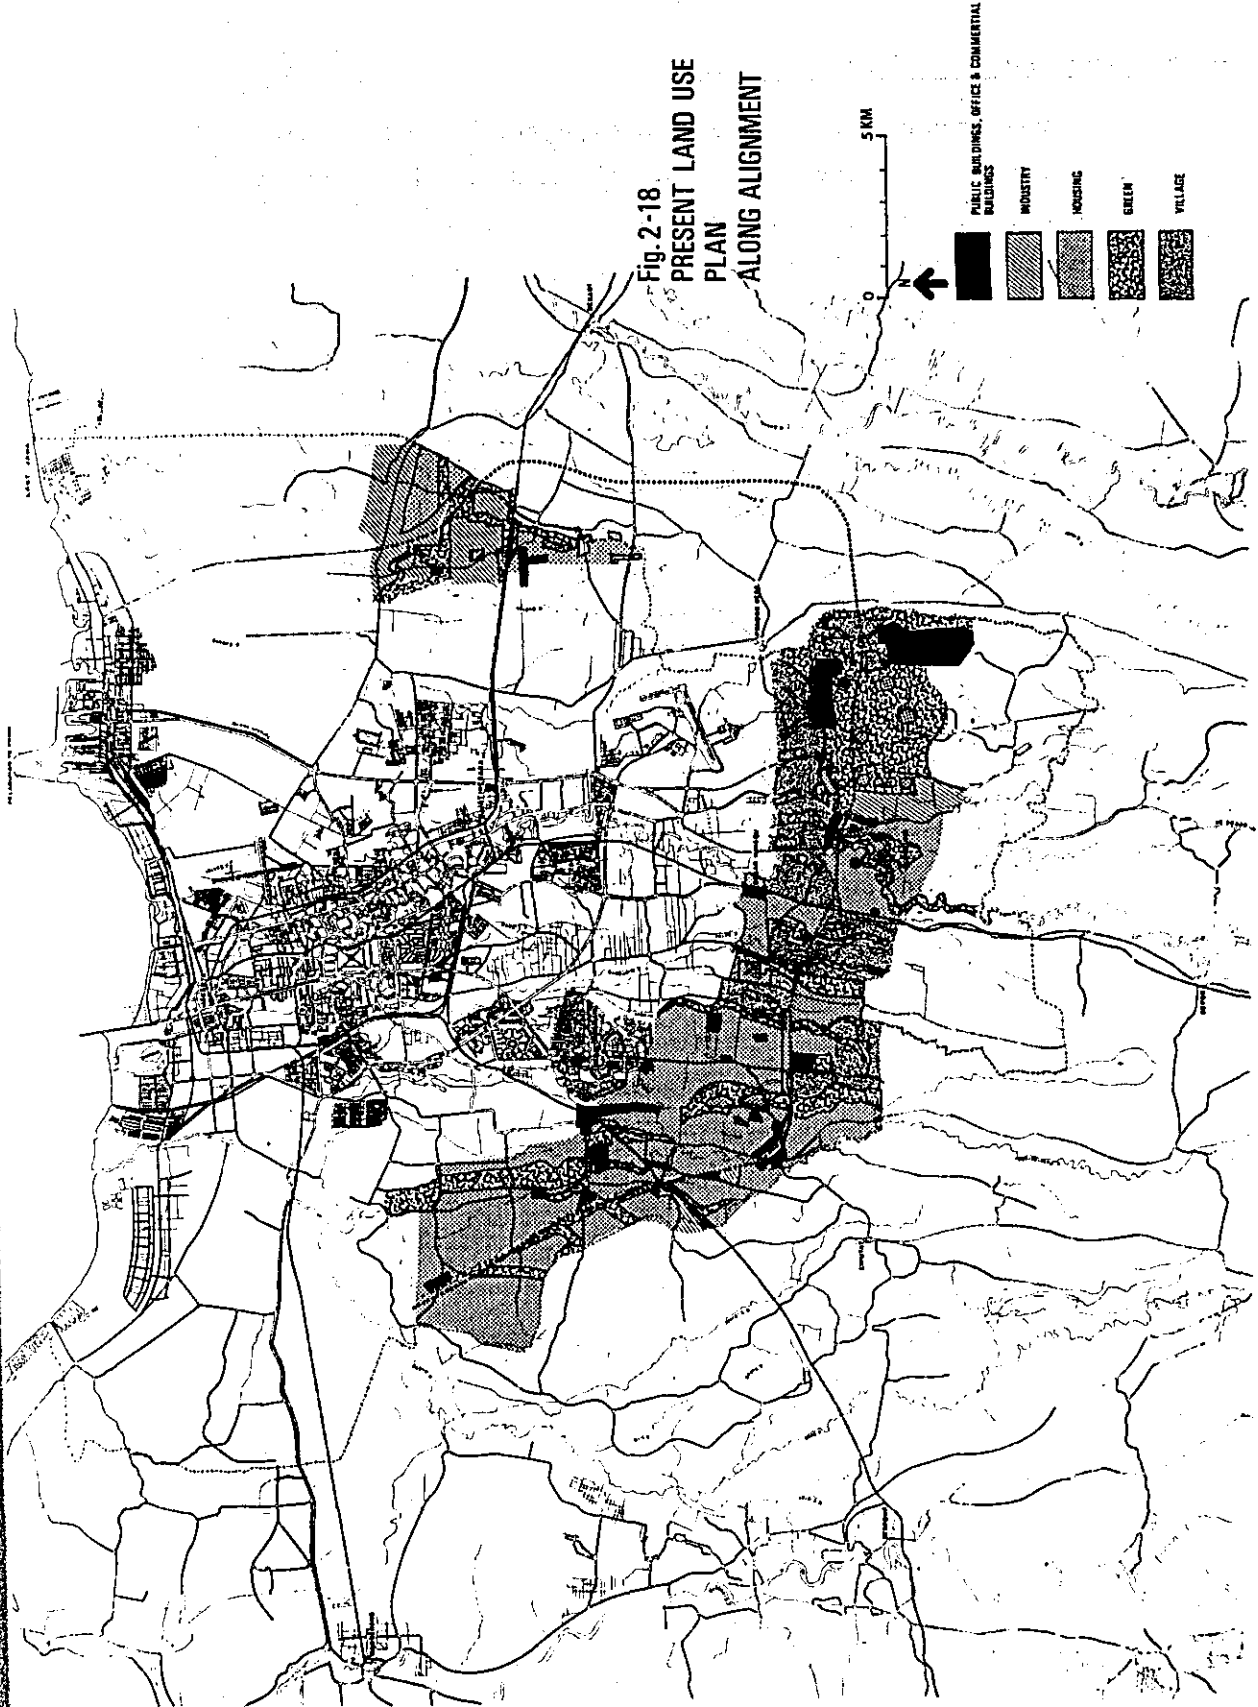

Fig. 2-18.
PRESENT LAND USE
PLAN
ALONG ALIGNMENT

2-3-4 Land Use around Interchanges

The area around interchanges is expected to become more valuable than the rest of the area along the Ring Road alignment in general. Therefore, it would be urged to establish land use regulations as well as the land use planning authorized as quickly as possible. And also, it would be preferable to acquire the land for public or semi-public usage prior to its development, in order to reserve the flexibility in design.

Facilities suitable to the area around interchanges are:

(1) For interchanges near residential areas

within 0.1 km: Green belt

within 1.0 km: Parks, gas stations, bus terminals, restaurants, shopping centers, hospitals, banks, post offices, recreational facilities, etc.

within 5.0 km: Housings, schools, hospitals, etc.

(2) For interchanges near industrial areas

within 0.1 km: Green belts

within 1.0 km: Gas stations, cargo terminals (with truck terminals, storages, packing yards, wholesale markets and/or manufacturing facilities), etc.

within 5.0 km: Industrial parks, research centers, etc.

2-3-5 Cargo Terminals

As the urbanization of DKI Jakarta proceeds, it will become more urgent to establish an efficient cargo traffic system. It is not only for the drastically increasing amount of goods consumption, but also, for freeing the CBD from congestions caused by the large volume of cargo traffics.

For this purpose, not only the organization of road networks or the improvement of vehicles, but also, cargo terminals of an adequate size and a proper location have to be constructed.

Fig. 2-19
EXAMPLES OF FACILITY LAYOUT
AROUND INTERGHANGE

The role of a cargo terminal can be divided as follows:

- Cargo transshipment;
- Storing; and
- Processing/Assembling

Among those listed above, the function of cargo transshipment is most basic. In the case of DKI Jakarta, in addition to it, the function of storing should not be neglected because of the lack of storages in DKI Jakarta. The function of processing/ assembling will not be studied assuming that it would be taken care of by adjacent manufacturing facilities.

For alternative locations, we propose four inter-changes on the Ring Road shown below.

| <u>Alternative Locations</u> | | | | |
|------------------------------|----|----|----------------------|----|
| | A | B | C | D |
| Inter-change Number | 1 | 9 | 11 | 13 |
| Zone Number | 16 | 31 | Outside 05 D.K.I. | 45 |
| Priority | 3 | 2 | (4) | 1 |

Those which will serve for the direction of Bekasi which is considered to become the largest in future are C and D. D which is next to the large industrial area is the best location. Next, B has the second priority because the flow in the direction of Bogor would become the second largest in future. C on the junction of the Ring Road and the Jakarta-Cikampek Highway is also important in terms of the traffic volume, but it has the low priority because of: the land use around; the long distance from the C.B.D., and also, its location outside of the D.K.I. boundary.

The relation between the number of truck terminals and storages, and the amount of goods carried by trucks is as follows:

- a cargo terminal for more than 5,000 tons/day of cargo carried;
- one additional cargo terminal when the amount of cargo exceeds 10,000 tons/day; and then,

- another additional cargo terminal when the amount of cargo exceeds 20,000 tons/day.

From the tonnage of cargo handled at cargo terminals, the proper size of truck terminals and storages can be calculated roughly as shown in Table 2-16.

For a cargo terminal with the function of transshipment and storing, the total ground area for those two facilities is said to be about 1/3 of the total area of a cargo terminal site as a whole including other facilities and the clearances between them. Therefore, when four terminals are constructed in the year, 2000, the total ground area would be about 115 ha with an average ground area of 86 ha per one terminal.

Fig. 2-20 PROJECTION OF GOODS CARRIED BY TRUCKS IN D.K.I. JAKARTA .(INCOMING + OUTGOING)

Table 2-17 AMOUNT OF CARGO & SIZE OF TERMINAL FACILITIES

| | 1985 | 1990 | 2000 |
|---|--------------------------------|-------|--------|
| Cargo Terminal | | | |
| - Cargo Handled at Cargo Terminal | 1,625 (1,000 tons/ year) | 3,914 | 10,593 |
| - Percentage in Total Cargo Carried by Trucks | 2.06 (%) | 3.22 | 4.28 |
| Truck Terminal | | | |
| - Cargo Handled at Truck Terminal | 812.5 (1,000 tons/ year) | 1,957 | 5,296 |
| - Truck Terminal Area | 3,250 (tons/day) | 7,828 | 21,186 |
| - Number of Berths | 7.5 (Ha) | 18.1 | 48.9 |
| | 108 | 260 | 706 |
| Storage | | | |
| - Cargo Stored | 812.5 (1,000 tons/ year) | 1,957 | 5,296 |
| - Storage Area | 10.1 (Ha) | 24.3 | 65.8 |
| - Number of Cargo Terminals Constructed | 1 | 2 | 3 or 4 |

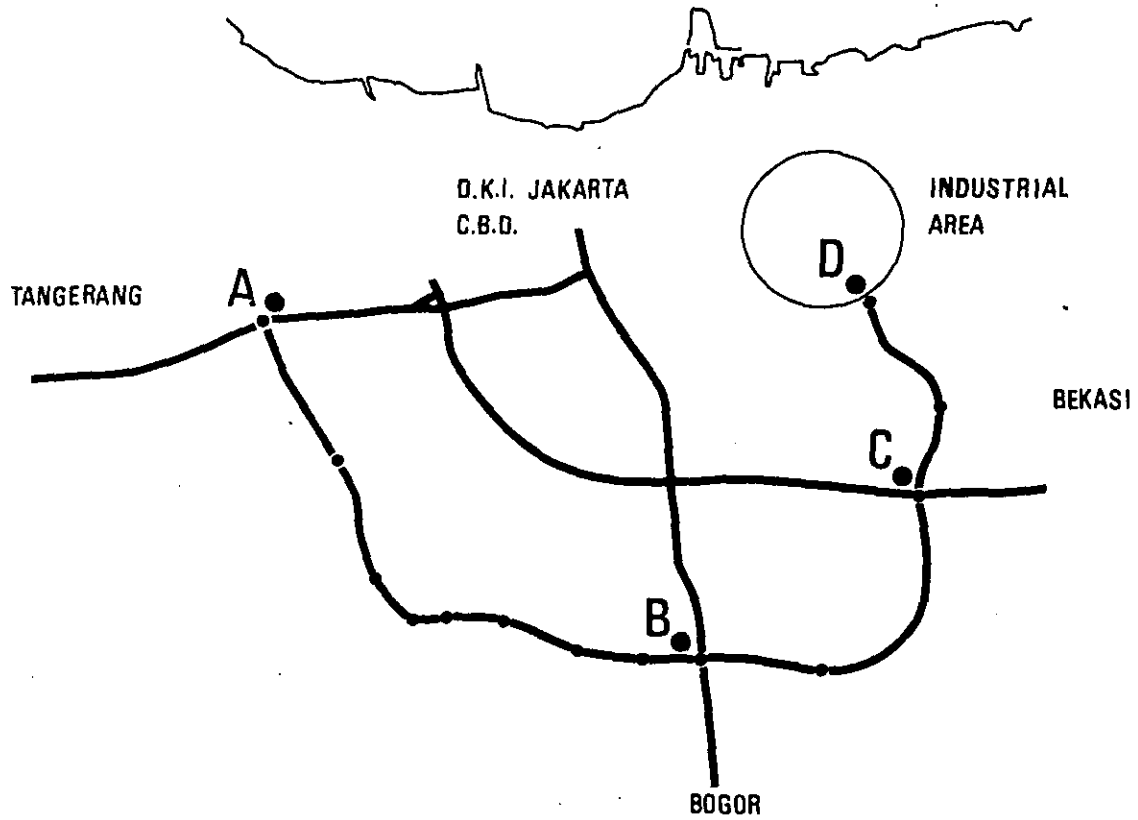

Notes: * Number of Average Cargo Terminal Operating Days per Year:
250 Days/Year.

* Unit Floor Area of Truck Terminal for Tonnage Cargo Handled:
M²/Ton.

* Frequency of Renewal of Cargo Stored: 6.2/Year.

* Unit Floor Area of Storage for Tonnage of Cargo Stored:
0.77 M²/Ton.

ALTERNATIVE LOCATIONS OF
CARGO TERMINAL

2.4 Arterial Road Network

2-4-1 Existing Arterial Road Network

The existing arterial road network in DKI Jakarta reflects the pattern of present activities as well as the process of its development.

Roads of the primary importance are: those connect Sunda Kelapa and Tg. Priok with the C.B.D.; and those extend towards Tangerang, Bogor and Bekasi from the C.B.D.

All of those primary roads are radial and they reinforce the concentric pattern of traffic flow in DKI Jakarta, and consequently, traffic congestions in the C.B.D. occur not only at peak hours, but sometimes all day long.

The existing Ring Roads which work for distribution of the incoming traffic over different directions are Jl. Let Jan S. Parman and Jl. Jan. Cratot Subroto.

The existing arterial road network is shown in Fig. 2-22.

2-4-2 Situation of Road Construction, DKI Jakarta

Almost all the primary and secondary roads in DKI Jakarta have been paved by now, but their drainage system is not sufficient enough, causing troubles during rainy seasons. The total length of roads in DKI Jakarta in 1973 was 1,800 km as in Table 2-17. The government maintained and improved those already constructed roads. But after 1974, the construction of additional road networks was started again, due to the economic development and increased traffic volume.

Table 2-18 Roads Construction, DKI Jakarta

| Year | Length of road | New road construction | Recon-struction | Up grading |
|------|----------------|-----------------------|-----------------------|-----------------------|
| 1970 | 1,011 km | - | 235 km | 127 km |
| 71 | 1,046 | - | 211 | 37 |

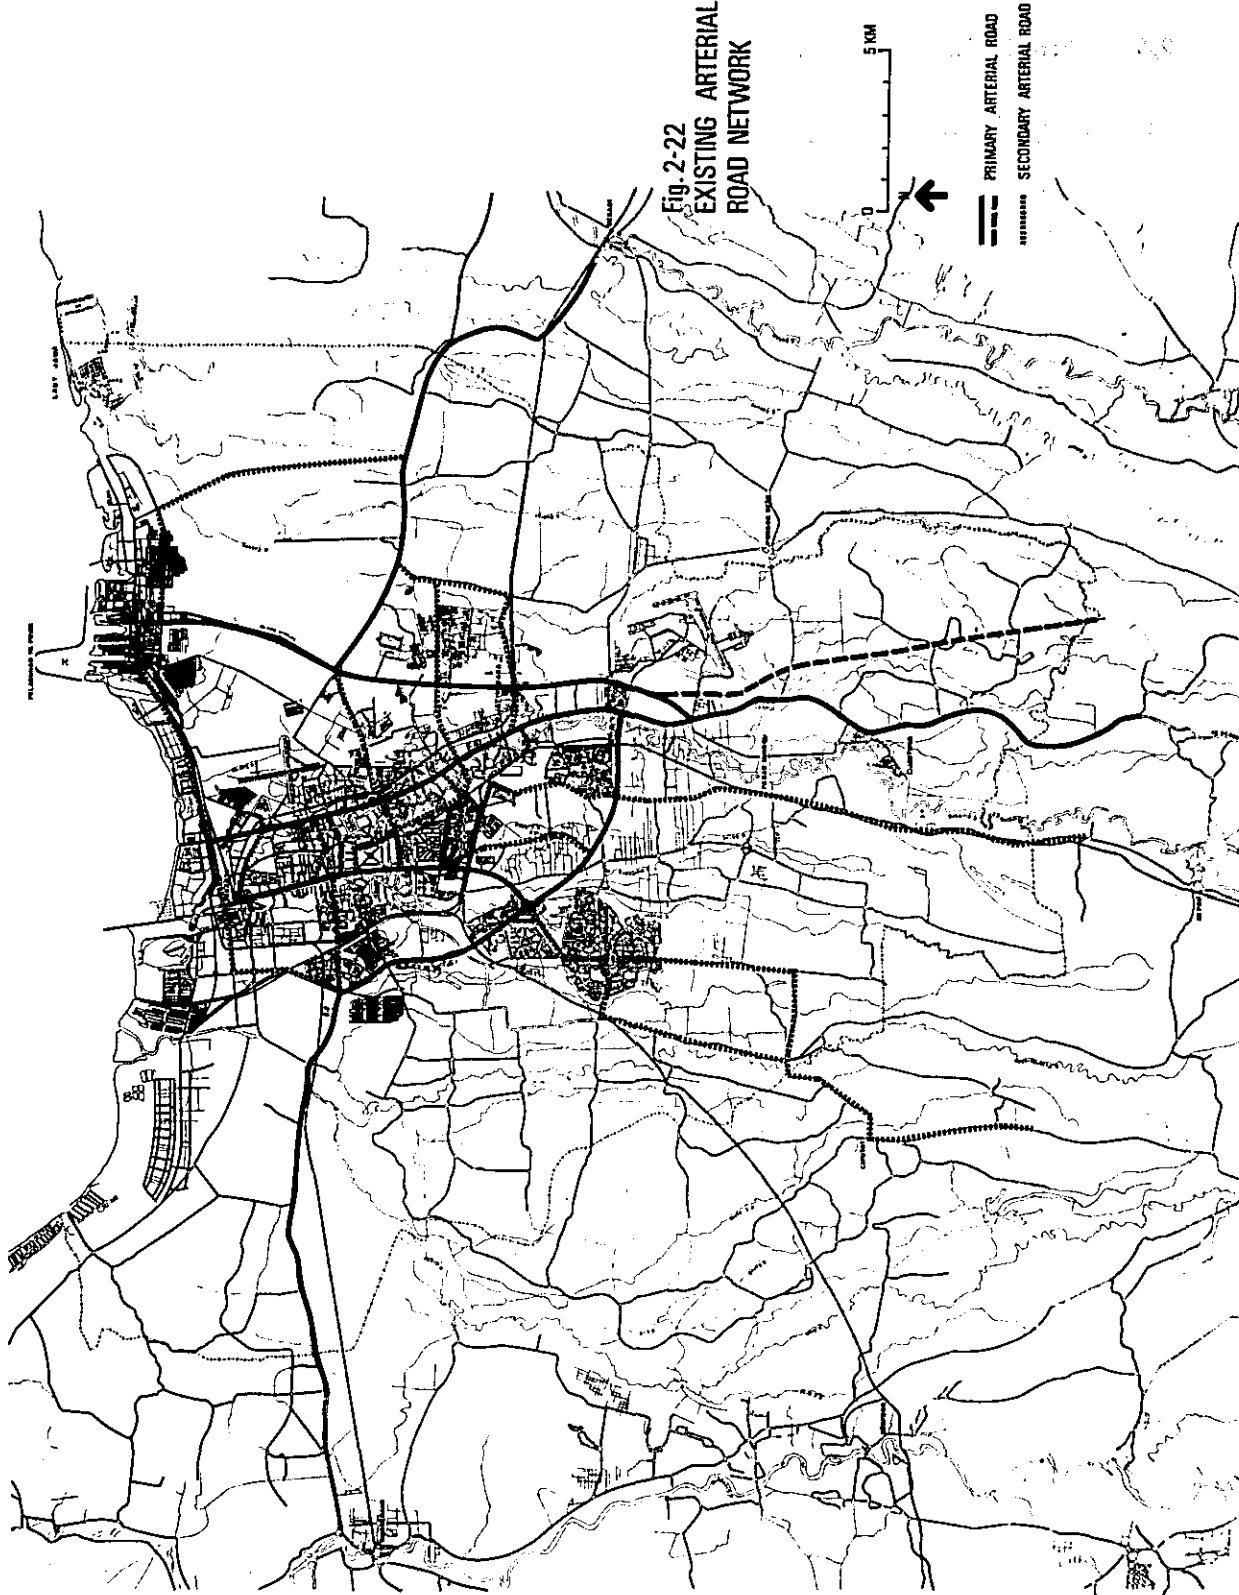

Fig. 2-22
EXISTING ARTERIAL
ROAD NETWORK

2-4-3. Future Arterial Road Network Plan

The planning of the future arterial roads network is based on the following policies:

- i) Three major Toll-Highways will serve for the incoming and outgoing traffic of DKI Jakarta and they are:
 - The Jakarta-Tangerang Highway
 - The Jagorawi Highway and
 - The Jakarta-Cikampek Highway
- ii) One of major roles of the Ring Road is to distribute efficiently the increasing radial traffic over destinations within it, after taking the incoming traffic on the periphery of DKI Jakarta.
- iii) The Intra-Urban Toll Road serves mainly for the long distance traffic within DKI Jakarta reducing the congestion in the C.B.D.
- iv) The Jakarta-Serpong Highway will be constructed, and also, other highways will be up-graded.
- v) Secondary roads in the future traffic situation in DKI Jakarta are studied as a part of the future road network plan as a whole.

The future arterial road network completed in each year is assumed as in Fig. 2-23 after examining the priority among the alternative networks based on the policy mentioned previously.

The condition of the future main highways will be as in the following Table.

| | 1985 | 1990 | 2000 |
|--|--|-----------|-----------|
| 1° Ring Road | Three cases in each target year are going to be studied in this report. They are: Case 1 : Completion of the whole alignment Case 2 : Completion of the West part only Case 3 : Without the Ring Road | | |
| Extention | incompleted | completed | completed |
| 2° Radial Highways: - Jakarta - Tangerang; - Jakarta - Cikampek; and - Jagorawi. | completed | completed | completed |
| 3° Intra - Urban Tollway | completed | completed | completed |

Note: Extension of the Ring Road is indicated by dots-line in Fig.2-23,

Consequently, the amount of roads constructions between 1976 and 2000 will be as in the table below.

| | 2 Lanes | 4 Lanes | Total |
|-------------|--------------------|-------------------|-----------------------------------|
| 1976 - 1985 | 49.0 ^{KM} | 6.0 ^{KM} | 51.0 ^{KM} , 122 LANE, KM |
| 1985 - 1990 | 41.9 | 12.3 | 53.2 , 131 |
| 1990 - 2000 | 42.6 | 12.2 | 54.8 , 134 |

Note: The total length includes lanes added.

2.5 Land Use Planning, DKI Jakarta

2-5-1 Residential Area

The minimum amount of green within a residential area is indispensable under the tropical climate of DKI Jakarta. Individual houses or terrace houses with green around will make a desirable living condition. Even in a district of high density, high rised apartments should be avoided as far as possible.

In Jakarta during the dry season the wind blows from the east or the north-east and during the wet season from the north or the north-west. The sunshine at a low angle at the moment of sunrise and sunset is strong enough to raise the interior temperature quickly. For those reasons, north facing houses with few openings on the east or the west are reasonable to take advantages of this specific climate.

The floor area ratio (F.A.R.) of a residential area with a group of residential buildings can be figured out from those figures in the diagram below. Among those, not only the ventilation or the amount of green, but also, the privacy depend on the ratio between the front clearance and the height of a building. Here, it is assumed to be about 1.5.

where, B = front

D = width

h = floor height: (3m)

n = Number of stories

E = Rate of Front-Clearance to Height: (1.5)

α = Rate of Side-Clearance to Width: (0.2)

$$= \text{F.A.R.} = \frac{DBn}{(D + EnH) (B + \alpha B)} \quad \frac{Dn}{(D + EnH) (1 + \alpha)}$$

- Individual Houses (n = 1) V = 0.533
- Terrace Houses (n = 2) V = 0.784
- 4 Stories Apartment (n = 4) V = 1.026

By assuming the floor area for a person, S (M²), the density of a residential area, P, is as follows:

$$P = 10,000 \times v/s$$

In a residential area the area reserved for the public facilities of various kinds is usually 50% of the area for residences. Therefore, the density of a residential area as a whole, B, is as follows:

$$P = \frac{10,000 \times v}{1.5 S}$$

In DKI Jakarta the average residential floor area per person is said to be about 12 M² according to the government policy. The desirable space is at least 20 M². For a residence of more than 2 stories, additional 2 M² of a building area is necessary for stair cases. Therefore, the density of a residential area by type of residences is as follows:

| | 12 M ² /Person | 20 M ² /Person |
|-----------------------|---------------------------|---------------------------|
| ◦ Individual Houses | 296 Persons/HA | 178 Persons/HA |
| ◦ Terrace Houses | 373 Persons/HA | 238 Persons/HA |
| ◦ 4 Stories Apartment | 489 Persons/HA | 311 Persons/HA |

A preferable residential area of a mixture of individual houses and terrace houses with 16 M² of floor area per person will have the density of 271 persons/HA. For a residential area of terrace houses and medium height apartments in the CBD with the floor area of 12 M² per resident, the density can be as high as 430 persons/HA, but in any case the maximum density should be below 490 persons/HA.

In 1976 the residential area in DKI Jakarta was about 20,300 HA including Kampung. The population of Kampung was 2,400,000 and the rest was 3,100,000. Therefore, the average density in Kampung is 418 persons/HA and that of residential areas outside of Kampung was 212 persons/HA. The population density of DKI Jakarta as a whole was 86 persons/HA.

Assuming the total residential area in the year, 2000 to be about 32,800 HA including 6,800 HA of the area of Kampung, the residential area outside of Kampung will be 26,000 HA.

The average annual growth rate of the Kampung population is assumed to be about 1.3%, and then, the Kampung population will

reach 3,280,000. The population outside of Kampung will be, therefore, 7,170,000.

So, the average Kampung density will be 483 persons/HA and the density outside of Kampung will be 276 persons/HA in the year, 2000. So, the capacity of population absorption by residential areas will reach its limit in the year, 2000.

However, in reality, there will be a considerable number of the residential population in the area of other uses. Assuming that the density of residential population in industrial areas is 50 persons/HA and that in commercial areas is 100 persons/HA in the year, 2000, then, the total population in those areas will be 670,000. By taking those into account, the Kampung density would be reduced to 450 persons/HA and the density of the residential area outside of Kampung would be reduced to 258 persons/HA.

2-5-2 Commercial and Administration Area

In 1971 the contents of work places classified into Sector III were as follows:

| | |
|---|-------|
| Electricity, gas and water | |
| Trade, restaurant and hotel | 33.3% |
| Financing and Insurance | |
| Transportation and communication | 12.7% |
| Community, social and personal services | 42.0% |
| Undefined | 12.0% |

In terms of their location, work places in Sector III are divided into two groups: ones located within commercial and administration areas; and those outside.

It is assumed that the number of work places outside of commercial and administration areas is 35% of the total work places in Sector III, and that it would be reduced to around 25% in the years, 2000, because of the increase of large scale organizations located in the CBD.

The distributions of work places within and outside of commercial and administration areas in each zone are done in proportion to the total floor area of commercial and administration facilities in each zone for the former group, and the total residential population for the latter group.

(1) Concentrated scheme

According to 'The Master Plan of DKI Jakarta, 1965-1985,' the number of work places per unit area will be about 160/HA in the year, 2000, and then, the total area of commercial and administration areas will amounts to 3,212 HA in the year, 2000, when the projected number of work places in Sector III is applied.

From the 'F.A.R. Regulation Map,' the average of the maximum F.A.R. in each zone in the CBD can be measured. The ratio between the actual F.A.R. in 2000, the F.A.R. of buildings constructed and the maximum F.A.R., is assumed as follows:

| | |
|----------------------|------|
| C.B.D. | 0.60 |
| Outside of C.B.D. | 0.35 |

The B.A.R., Building Area Ratio or the ratio between the building area and the ground area, in commercial and administration areas is assumed as follows:

| | |
|----------------------|------|
| C.B.D. | 0.85 |
| Outside of C.B.D. | 0.90 |

Then, the ratio between the actual floor area and the ground area by zone would be as shown in Table 2-18, and the total floor area in the commercial and administration area will be 2,961 HA in the year, 2,000. The unit floor area per work place will be 14.9 M² and this is considered to be a reasonable number.

This 'Concentric Scheme' of the CBD generally shares its basic concept with 'The Master Plan of DKI Jakarta, 1965-1985,' and it aims at the continuous enlargement of the present CBD. However, a rough estimate of the commuting population to the enlarged CBD is proved to exceed the capacity of the future road networks. This is why the 'Dispersed Scheme' of the commercial

and administration facilities has to be studied.

(2) Volume of commuting traffic and capacity of traffic networks
In the 'Concentrated Scheme' previously mentioned, the number of work places in Sector III in the CBD is estimated to be 1,085,000 and the employed population in Sector III to be 277,000. In the same scheme the number of work places in Sector III in DKI Jakarta as a whole is 2,656,000, and so, those outside of the CBD amount 1,571,000.

The employed population in Sector III in DKI Jakarta is 2,183,000, and so, the commuting population into DKI Jakarta is:

$$2,656,000 - 2,183,000 = 473,000$$

And the commuting population into the CBD from outside of DKI Jakarta is:

$$473 \times 1,085 / 2,656 = 193,000$$

The number of employed population in DKI Jakarta, and at the same time, outside of the CBD is:

$$2,183,000 - 277,000 = 1,906,000$$

In this employed population, the number of people who commute into the CBD is:

$$1,906,000 \times 1,085,000 / 2,656,000 = 779,000$$

As a result, the total of commuting from the outside of the CBD into the CBD is:

$$193,000 + 779,000 = 972,000$$

Assuming that during the peak hour, from 8:00 AM to 9:00 AM, 50% of the total commuting would occur, the number of commuting population is 486,000.

The capacity of commuting into and from the CBD is checked by setting 17 nodal points shown in Table 2-24, and it is estimated to be 560,000 cars/day. In addition to it, the commuting by the Intra Urban Highway is estimated to be 152,000 cars/day.

Besides that, amount, the capacity of the number of narrow streets is taken into account, 5%. Then, the total capacity of the future road network crossing the boundary of the CBD would be 747,000 cars/day in total in the year, 2000.

According to the survey, the capacity during peak hours reaches 8% of a day, and also, that the number of passengers carried by a vehicle during peak hours is 13 persons/vehicle.

Therefore, the total capacity of the future road networks would be:

$$747,000 \text{ cars/day} \times 0.08 \times 13 = 777,000 \text{ persons/hour}$$

Those carried by the railway would be about 28,000 persons/hour by our estimation.

Then, the total capacity of commuting into and from the CBD would reach 805,000 persons/hour, and that of one way would be 50% of it, 402,500 persons/hour.

'Dispersed Scheme'

By the studies mentioned above, it has become necessary to allow only the amount of work places which generate the traffic not exceeding the capacity of the future traffic networks. In other words, the balance between the development of the CBD and the traffic facilities planned has to be kept. Then, the amount of work places which has to be removed is:

$$\frac{\text{Capacity of Traffic Networks}}{\text{Commuting Population}} = \frac{402.5}{486.0} = 0.8$$

In dispersing the commercial and administration areas along the Ring Road alignment, those areas of the south of Pondok Indah and Pasar Minggu are suitable as mentioned in '2-3-3 Land Use along the Ring Road.' In the 'Dispersed Scheme' the floor area reduced from the CBD and its surroundings is distributed into sub-centers.

The total ground area of the commercial and administration land use in the 'Dispersed Scheme' is about 10% smaller than that in the 'Concentrated Scheme' due to the lower F.A.R. on the periphery than in the CBD.

Fig. 2-24

| 6 | 38 | 63 | 24 | 16.1 | 19.7 |
| 12 | 207 | 148 | 306 | 205.4 | 84.4 |
| 31 | 48 | 140 | 67 | 45.0 | 36.6 |
| C.B.D. Total | 1,079 | 150 | 1,617 | 1,085.3 | 277.3 |

Note: The percentages of the area within C.B.D, in the following zones are:

| Zone No. | Percentage |
|----------|------------|
| 5 | 50% |
| 6 | 30% |
| 12 | 70% |
| 31 | 30% |

Fig.2-25
COMMERCIAL AND/OR ADMINISTRATION
DISTRICTS IN DISPERSED SCHEME

2-5-3 Industrial Area

Because of the wind direction in DKI Jakarta, it should be avoided to locate large factories with obnoxious effects on the environment on the northern coast. In 'The Master Plan of DKI Jakarta, 1965-1985' the industrial area is largely concentrated on Progadung Area and it would be better to be dispersed. Industries which should be close enough to their market would be better to be located along the Ring Road alignment, preferably outside, and those which should be close to the sources of materials should be located in the local area.

According to 'The Master Plan of DKI Jakarta, 1965-1985,' the number of work places classified into Sector II per unit area is 160/HA. When the projected total number of work places is applied, the industrial area amounts to 6,950 HA.

2-5-4 Others

(1) Institutional area (administration excluded)

The area for institutional facilities, namely schools, hospitals, etc., was 570 HA in 1973, and this was 1,146 M² for a person. Assuming that it will be in proportion to the population of DKI Jakarta, 1,205 HA will be necessary in 2000.

(2) Agricultural area

According to the 'JMATS' report, the area reserved for the agricultural area will be transformed to residential areas, and also, the number of work places in Sector I per unit agricultural area will increase in future.

Assuming that the total agricultural area would be reduced to 7,663 HA in 2000, the number of work places in Sector I per unit area, 2.1 / HA can be obtained by applying our projection of work places in Sector I.

(3) Open spaces

The land uses which fall onto this category are:

- Area reserved for infrastructure;
- Park area; and
- Green

Fig. 2-26

MANUFACTURING INDUSTRY LOCATIONS

The total amount of Open Spaces in 1973 was 12,300 HA which was about 18.7% of DKI Jakarta, and this would increase slightly in the year, 2000 to 13,780 HA, 21%.

Assuming that the area for infrastructures will occupy 10% of the total area of DKI Jakarta, the recreational areas, namely Parks and/or Green, would be 11%, 7,218 HA. This is about 7 M² per resident.

2-5-5 Land Use Framework

From the present land use and our land use plan in 2000, the land use situation at the intermediate points, 1985 and 1990, can be obtained, Table 2-20.

Residential, Commercial and Administration, and Industrial Area are figured out by applying the intermediate number of work places per unit area. Institutional area is in proportion to the total population. And other statistics are by straight line projections.

Table 2-20 D.K.L. JAKARTA LAND USE

Fig. 2-27
URBAN FUNCTIONS

2.6 Forecasted Figures by Zone

2-6-1 Land Use

By reducing the area of the Seribu Island from the total of Kecamatan in DKI Jakarta, the total area of the forty one zones dealt with in this report can be obtained.

On the 'Zoning Map' the area of each zone can be measured, and then, it is distributed into four major land uses referring to those maps as follows:

- Land Use Map, DKI Jakarta, 1973
- DKI Jakarta Land Use Plan, 2000, Dispersed Scheme
- DKI Jakarta Land Use Plan, 2000, Concentrated Scheme

2-6-2 Residential Population in Jakarta by Zone

a) Present residential population

The 'Kecamatan' population can be found in 'statistic Wilayah DKI Jakarta 1970-1976.' By adding up the populations of 'Kacamatan,' the population of each zone can be obtained.

In case of boundary line cuts across a 'Kecamatan,' the population of the smaller administrative unit, 'Kelurahan,' was used instead.

b) Future residential population

By projecting the population development in the past while taking the area of residential land uses and its density into account, the residential population in the year, 2000, are figured out.

The density in residential areas is kept lower than 500 person/HA.

2-6-3 Residential Population in BoTaBek Area by Zone

Approximately, the population of 8,590,000 is assumed in the 'BoTaBek' area in the year, 2000. Here, the distribution of the increased portion of it is going to be studied.

Fig. 2-30 POPULATION PROJECTION IN WILAYAHS

The population added after 1975 can be divided into the natural increase and migration. It is assumed that the natural increase occurs proportionally to the residential population, and the migration depends on the specific location of new developments in each zone.

By taking the size and the locations of projects mentioned in the 'Jabotabek' report into account, the portion of population increase by migration is distributed as follows:

Table 2-23 Population Increased by Migration in Bo.Ta.Bek. Area

| Zone # | Tangerang | Zone # | Bogor | Zone # | Bekasi |
|--------|-----------|--------|---------|--------|---------|
| 42 | 210,000 | 49 | 400,000 | 57 | 237,500 |
| 43 | 240,000 | 50 | 100,000 | 58 | 175,000 |
| 44 | 225,000 | 51 | 145,000 | 59 | - |
| 45 | 60,000 | 52 | 145,000 | 60 | 227,500 |
| 46 | 30,000 | 53 | - | 61 | - |
| 47 | - | 54 | 80,000 | 62 | - |
| 48 | - | 55 | 120,000 | | |
| | | 56 | - | | |
| Total | 765,000 | Total | 990,000 | Total | 640,000 |

Then, the natural increase is distributed into zones proportionally to the residential population of each zone.

2-6-4 Population Classified by Shelter Conditions

The present classification by zone is in 'Statistic Wilayah DKI Jakarta, 1976' and that of future is obtained by adjusting the projection in '2.2.2 Classified Population' by specific condition in each zone.

| | 531.0 | 3.7 | 144.9 | 382.4 |

2-6-5 Population Classified by Density

The classification is done according to the criteria as follows:

- a. Less than 250 persons/HA
- b. From 250 persons/HA to 400 persons/HA
- c. More than 400 persons/HA
- k. Kampung population, 446 persons/HA in 1985 and 483 persons/HA in 2000.

By reducing the Kampung population from the total, the average density in residential areas in each zone can be obtained, and then, the distribution of the classified population according to the above criteria is decided.

2-6-6 Employment by Zone

The present ratio among the employment in Sector I, Sector II and Sector III can be obtained for each of the five Wilayahs in DKI Jakarta.

The total of the employed population in each zone is in proportion to the total population of each zone. The employment in Sector I in each zone is in proportion to the area of agricultural land use. The remaining is divided into the employed populations in Sector II and III according to the ratio between residential population.

2-6-7 Work Places by Zone

1) Sector I

Assuming no commuting in Sector I, the population employed in Sector I is considered to be the same as the one in work places in Section I.

2) Sector II

As mentioned in '2.4.3 Work Places,' work places in Sector II can be divided into: work places in industrial areas, (A); and those outside, (B). The ratio between the two is assumed to be 65:35 in 1971 and 75:25 in 2000.

(A) in 1975 is distributed among zones proportionally to the number of manufacturing factories and that in 2000 to the total area of the industrial land use. (B) is distributed proportionally to the total area of the residential land use.

3) Sector III

As mentioned before, work places in Sector III can be divided into: work places in commercial and administration areas, (A); and those outside, (B). The ratio between the two is assumed to be 65:35 in 1971 and 75:25 in 2000.

(A) is assumed to be proportional to the total floor area of commercial and administration facilities.

The total floor area of commercial and administration facilities in 1973 in each zone is obtained from the area of commercial and administrative land use multiplied by the F.A.R. in the CBD and by assuming 200% of F.A.R. in the rest.

That in 2000 is figured out from the maximum F.A.R., the ratio between the actual F.A.R. in 2000 and the maximum F.A.R., and B.A.R. as mentioned in '2-5-2 Commercial and Administration Area.'

(B) is distributed proportionally to the residential population in each zone.

Table 2-34 Population, Work Places and Employment, D.K.I. Jakarta

2-7 Regulations and Guidance for Land Use

In relation to the future land use planning in the periphery of Jakarta, a multi-nuclues type of city shall be proposed for urban planning.

In its implementation, however, adequate regulations and guidance on the basis of the established criteria are of primary importance so that all the activities should properly be arranged in line with the principle when planning as a multi-nuclues city.

The following are outlines of establishing such criteria in preparation for adequate regulations and guidance:

(1) Classification of land use

More detailed classification will be needed such as:

- a. Industrial areas
 - a-1. Areas for heavy industry
 - a-2. Areas for light or ordinary industries
- b. Commercial areas
- c. Business areas
- d. Residential areas
 - d-1. Residential areas for exclusive use
 - d-2. Ordinary residential areas

One thing important other than such classification is that the areas permitting or not permitting "location" shall clearly be designated in each area. Particular consideration shall be given to the areas where multi-use of the land be permitted.

(2) Regulations for implementation

- a. It can be proposed that any plans of buildings or other facilities shall be subject to the "permission" or the "permission for land use" rather than the mere "acknowledgement of application" for buildings or other facilities.
- b. When the buildings or other facilities planned and applied may obstruct the future urban planning, they shall not, in principle, be permitted unless they are;
 - i) temporary buildings or facilities, or
 - ii) subject to the restrictions with respect to their use and scale.

c. High rised buildings may adapt to the future development, however, regulations shall be applied to the volumetric occupancy as well as structural and formative respects.

Such regulations shall include;

i) Setback or obliquity of the buildings designed to get wider view, more sunlight and efficiency of ventilation.

ii) Non-occupied areas providing the space for public works or emergency refuge.

(3) Others

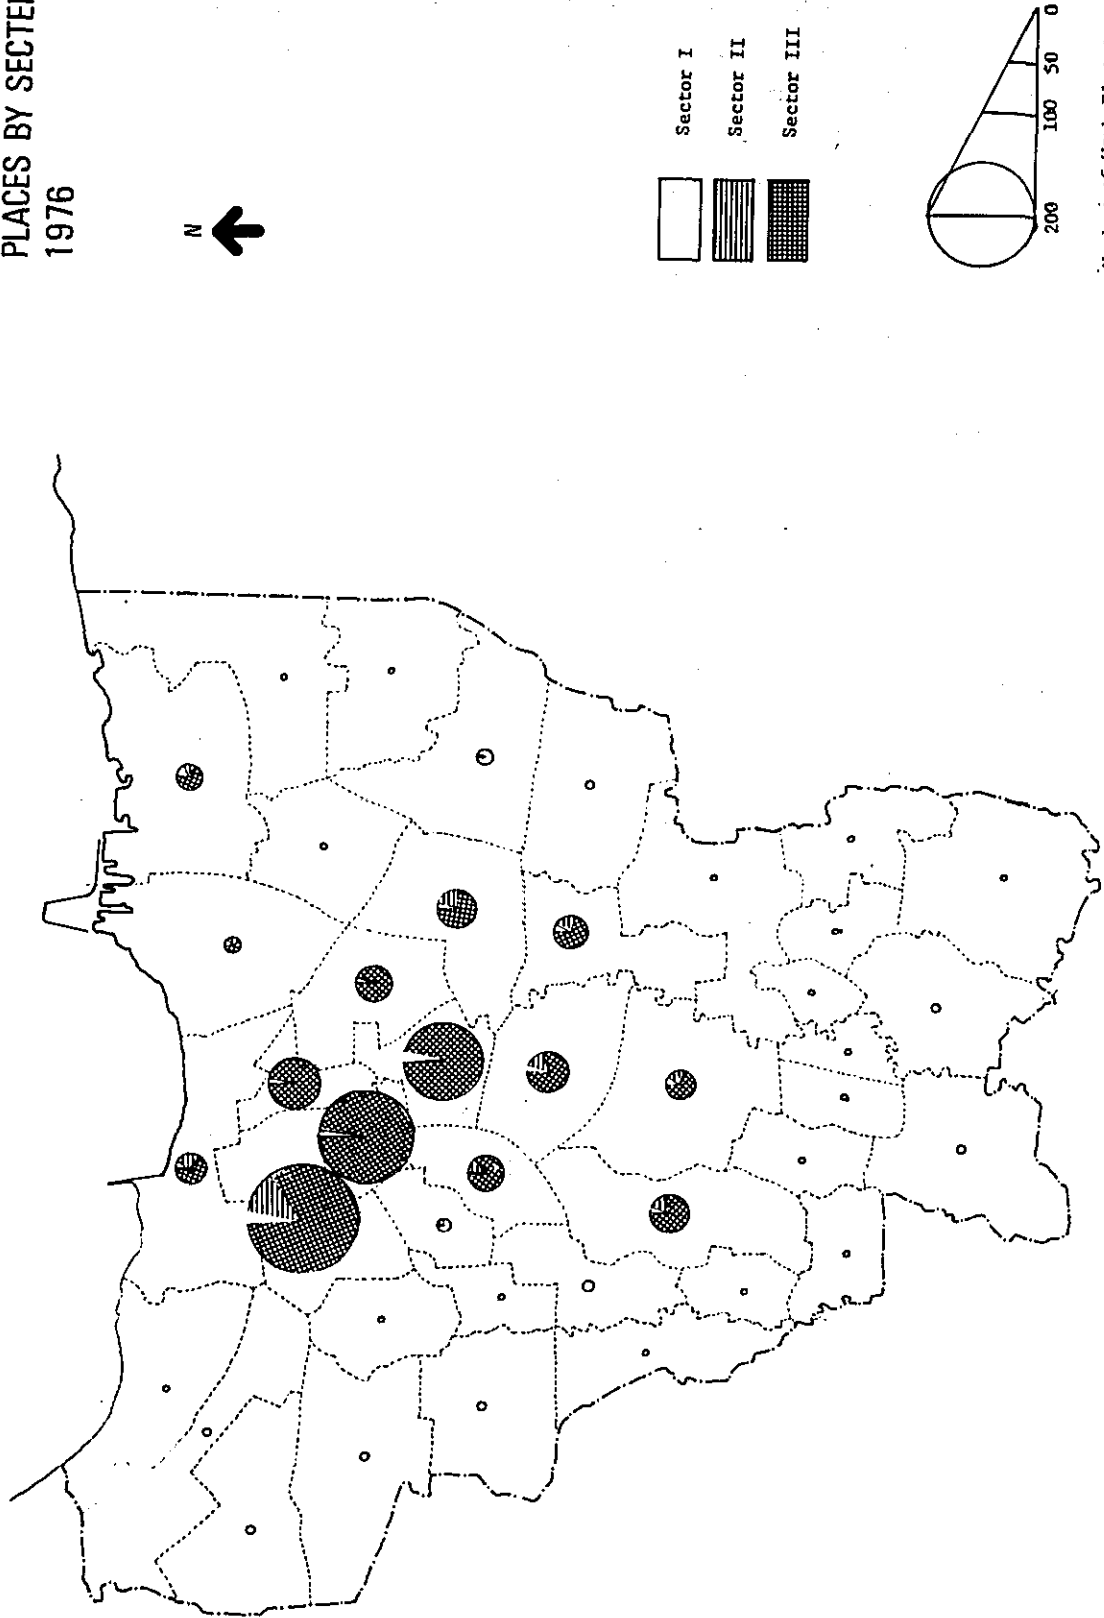

a. Release from the regulations in the case of agreement by all those holding titles to an estate (Excepted regulations).

b. Area development with the right of expropriation of land.

c. Establishment of financing system to the area development program for business, industrial and housing complex.

By establishing the criteria and taking legal steps, as referred to the above, adequate regulations and guidance can be attained.

CHAPTER 3 TECHNICAL STUDY AND ANALYSIS

3.1 Geological Analysis

3-1-1 Geological Conditions of Study Area

(1) Geological situation

The surrounding of Jakarta is basically formed of sedimentary rocks of the tertiary era, overlaid with volcanoclastic materials of the quaternary diluvial epoch. Along the river sides, alluvial layers are accumulated, and tertiary rocks are not outcropped. The volcanoclastic materials are of clay, sandy soil, gravels and these mixtures, and in the study area the surface layer is considerably stratified and it is composed mainly of clayey soil. This clayey soil weathered under the high temperature and humidity environment over extensive depth, part of it forming purplish-red to brown lateritic clay with very high water content. Where weathering has not progressed, the volcanoclastic materials are mainly of black and gray cohesive soils and they are hardened.

(2) Geomechanics

From the results of the soil surveys, the physical properties of the lateritic cohesive soil which greatly affects the proposed project are as listed in Table 3-1, and the CBR value and N value together with the locations where samples were obtained, are shown in Fig. 3-1.

Table 3-1 Results of Physical Tests of Volcanic Cohesive Soils

| Soil Classification | Unified soil classification: CH-MH (cohesive soil) | | |
|------------------------------|---|--------------------|---------------|
| | AASHO soil classification: A-7 | | |
| Specific gravity | GS | | 2.4 ~ 3.0 |
| Natural moisture content | W _n | % | 23 ~ 123 |
| Liquid limit | LL | % | 50 ~ 110 |
| Plastic limit | PL | % | 35 ~ 70 |
| Plasticity index | I _p | | 15 ~ 65 |
| Unit weight | γ _t | g/cm ³ | 1.5 ~ 2.0 |
| Maximum dry density | γ _d max | g/cm ³ | 1.3 ~ 1.6 |
| Optimum moisture content | W _{opt} | % | 2.0 ~ 40.0 |
| Field CBR | | % | 1.5 ~ 13.0 |
| Undisturbed soaked CBR | | % | 1.0 ~ 8.0 |
| Modified soaked CBR | | % | 2.3 ~ 9.8 |
| Water absorption swelling | γ _e | % | 0.004 ~ 0.095 |
| Cohesion | C _u | Kg/cm ² | 0.07 ~ 0.68 |
| Angle of shearing resistance | φ _u | (°) | 6.5 ~ 22.5 |
| Consolidation index | C _c | | 0.47 ~ 0.99 |

3-1-2 Geomechanics and Earthwork Plan

(1) Embankment

The project road will traverse through the diluvial upland covered with the lateritic soil and the paddy field of the alluvial plain accumulated soft soil layers. As embankment materials, the volcanic clay is low in bearing strength when disturbed and ample care has to be taken during compaction in the process of construction. Also, the low laying area of sedimentary layer dissected up by minor rivers are estimated to be of soft soil with poor bearing strength so that embankment works on this soil has to be conducted slowly.

Fig. 3 - 1
SUMMARY OF SOIL SURVEY
TEST RESULTS

| Boring No. ▽ | Specific Gravity Gs | M. I. T. Classification | | | | Atterberg Limits | | | Classification Unified | Maximum Dry Density γ_d g/cm ³ | C.B.R. |
|-----------------|------------------------|-------------------------|--------|--------|--------|------------------|--------|--------|------------------------|--|--------|
| | | Gravel % | Sand % | Silt % | Clay % | L.L. % | P.L. % | P.I. % | | | |
| 1. | 2.657 | - | 7 | 22 | 71 | 93.20 | 39.91 | 53.29 | CH | 1.305 | 5.30 |
| 2. | 2.611 | - | 8 | 30 | 62 | 91.60 | 39.20 | 62.40 | CH | 1.305 | 7.80 |
| 3. | 2.592 | - | - | 34 | 66 | 95.50 | 43.05 | 52.45 | CH | 1.310 | 4.47 |
| 4. | 2.543 | - | - | 42 | 58 | 93.90 | 36.92 | 56.98 | CH | 1.192 | 4.50 |

The soft and weak soil layer in the project area is for a 3 km stretch on the west route and for a 6 km stretch on the east route. From the data of various soil studies, the extent of settlement according to the height of embankment are estimated as shown in Table 3-2.

Table 3-2 Settlement against Height of Embankment
(in m)

| Depth of Soft Soil | Embankment height | | |
|--------------------|-------------------|-----|-----|
| | 3 m | 4 m | 6 m |
| 0 ~ 3 m | - | 0.3 | 0.5 |
| 3 ~ 5 m | 0.3 | 0.5 | 0.8 |
| 5 ~ 8 m | 0.5 | 0.8 | 1.2 |

At the preliminary design stage, the methods of embankment works at the soft soil zone are proposed as follows:

- (a) For the stretch along the west route where the soft soil layer is comparatively shallow, the stretch may be removed of the soft soil and replaced with better quality soil, in order to prevent the deformation of the road surface of the low embankment and to reduce settlement of embankment or structures of the replaced soil so that long term stability may be obtained.
- (b) Where the soft soil layer is deep and/or the embankment is high, preloading method may be adopted, as for the Jagorawi Highway, whereby consolidation settlement is applied to the soft soil layer, and subsequently the excess top layer is removed to finish the embankment to predetermined height in order to contain the settlement within allowable limit. Sand for a depth of 1 m is layed on the roadbed and the water that is emitted from the foundation and the embankment is removed from the sides of the embankment. The consolidation time for a soft soil layer of about 60 cm in height is estimated to be about 6 to 7 months.

(2) Gradient of slope

Gradient of slope should be designed safely enough respectively the kind and situation of soil and the height of earthwork. The clay and clayey soil in the project area classified in the unified classification as CH, MH is rich in cohesiveness so that for an embankment of about 6 m in height a slope of 1.5:1-1.8:1 and for a cut portion of 10 m in height a slope of 0.8:1~1.2:1 are considered standard stable values.

The Indonesian standard of slope gradient (4:1 for embankment, and 3:1 for cut) is much more gradual than these stable gradient values. However, from the topography and vertical profile of the Ring Road, if the Indonesian standard is adopted for the high cuts and embankments for the hilly areas and river basin regions, the land requirement will be very great and the earthwork volume will largely increase. Therefore, for the study area, with due consideration to the rainfall characteristics, geology, and underground water situation, the following values are adopted as the gradients for the slopes classified by height of the cut or embankment.

Table 3-3 Gradient of Slope

| Height (m) | Embankment | Cut |
|---------------------|------------|---------|
| 0 ~ 2.5 | 4 : 1 | 3 : 1 |
| 2.5 ~ 4 | 3 : 1 | 2 : 1 |
| 4 or more | 2 : 1 | 1.5 : 1 |
| Indonesian criteria | 4 : 1 | 3 : 1 |

Deciding the gradient of slope as above, more than 70% of the alignment of the project road have come to be the minimum width of the criteria.

In Fig. 3-1-2 is shown the relation between the gradient of slope for embankment and cut and the necessary width of right-of-way.

Fig. 3-1-2 RELATION BETWEEN GRADIENT OF SLOPE AND R.O.W WIDTH.

3-1-3 Foundation of Structures

(1) Survey

To determine the type of foundation for structures, rotary boring survey with standard penetration test was performed for the locations where major bridges are proposed. The boring was performed to a planned depth, but was terminated where the N value of over 50 continued for more than 5 m. Penetration test was performed at 1 m interval. Generally it was noted that at the plain near the coast the bearing stratum is quite deep and tends to become shallower for the gradual slope region further inland. The results of the survey are as shown in the previous Fig. 3-1 and the location where N value of over 50 continued for over 5m as shown in Table 3-4 together with the depth reached.

Table 3-4 Depth of Bearing Stratum

| No. | Location of boring | Depth of stratum (m) |
|-----|---|----------------------|
| 1 | Junction with Jakarta-Tangerang Hwy | 5 |
| 2 | Proposed pier site of Pesanggrahan River Bridge | 11 |
| 3 | Proposed pier site of Cilliwung River Bridge | 3 |
| 4 | Junction with Jakarta-Cikampek Hwy | 17 |
| 5 | Junction with Jl. Jakarta-Bekasi | 22 |

Note: The bearing strata were of hardened sandy soil.

(2) Determination of foundation works

Other than some exception, the bearing stratum in the study area is generally at about 5 ~ 20 m below the existing surface, and the pile foundation work is proposed.

As the piles, considering the length of pile, quality of materials, driving capability, moment of inertia, etc., in RC pile and the steel pipe are determined.

The comparative studies of various types of piles are made as shown in Table 3-5. Through examination, following determination

for the foundation is done.

| <u>Depth of the bearing stratum</u> | <u>Type</u> |
|-------------------------------------|---------------------------|
| 0 m ~ 5 m | Spread foundation |
| 5 m ~ 12 m | RC Pile, 400 mm |
| 12 m ~ 22 m | Steel Pipe, ϕ 600 mm |

Additional checking of foundation types, at the stage of the detailed engineering with soil surveys should be needed to decide to proper foundation type.

Table 3-5 COMPARATIVE EVALUATION OF DIFFERENT TYPES OF PILES

(1)

| Depth of Bearing Stratum | 0 - 5 m | | 5 - 12 m | | 12 - 22 m | | | | Overall (1) | | | |
|--------------------------|--|--------------------------|--|----------------------|--|--------------------------|---|----------------------|--|--|--|--|
| | Material Quality | Availability of Material | Reliability in Construction | Fabrication Problems | Material Quality | Availability of Material | Reliability in Construction | Fabrication Problems | | | | |
| Evaluation of Foundation | Spread Foundation | (A) | - | - | - | - | - | - | - | | | |
| | R.C. Pile | B | (A) | A | A | A | C | A | B | | | |
| | P.C. Pile | B | B | B | B | A | A | C | B | | | |
| | Steel Pile | B | B | A | A | B | A | A | (A) | | | |
| Cast-in-Placed C-Pile | B | B | B | B | A | A | C | A | B | | | |
| Remarks | Spread foundation is the most economical of all foundation types and it is so easy for the construction. | | R.C. pile can be driven without joint and the most economical of all kind of foundation piles. | | P.C. pile requires high strength concrete and maintenance of quality control is difficult. | | R.C. pile is liable to cracks and damage of pile head and cast in place concrete pile is liable to interference of disturbed foundation at the pile head. | | R.C. has to be fabricated at factories to be newly established and even if fabricated at the plant, the problem of control of manufacturing remains. | | Although there is a problem of availability, steel pile is considered most favorable | |

(2)

| Steel Pile | Kind of Pile | Moment of Inertia | Economy | Overall (2) |
|------------|-----------------|-------------------|---------|-------------|
| | | H-Pile | B | B |
| | Steel Pipe-Pile | A | A | (A) |

(3) Of the steel pipe pile, both the 400 - 600 class may be driven with medium capacity driver, but considering the saving in work period with larger diameter piles, the 600 pipe pile is considered for this study.

3-2 Material Surveys

3-2-1 Survey of Quarries

The study team made an extensive survey of the quarries over a wide area in the periphery for the 46 km proposed Ring Road, fully taking into consideration the available geological map for the study area, and the data from construction works of Jagorawi Highway which is an interurban highway within the study area.

The surveys made studies on the existing situation of quarrying, the production capacity and the quality of materials. The studied locations are as shown in Fig. 3-2 and the results summarized in Table 3-6. The use of aggregates for the Jagorawi Highway construction are as follows:

- (a) Use of aggregates are in accordance with the ASHO standards.
- (b) Coarse aggregates are of gravels excavated from the riverbed of Citeureup River at Kedungmanggu and crushed at the site office.
- (c) Fine aggregates are purchased from suppliers in Bogor.

3-2-2 Aggregates Procurement and Implementation Plan

Since there is no aggregate supply source near the project area, and the materials excavated at cut portions do not contain suitable pavement materials, and also as the construction period for the project coincides with the construction period of other projects, it is anticipated that the procurement of aggregates will have a great bearing on the implementation of the project.

Basically, since the quarry site of the basalt hill at G. Putric which is 20 km from the project site, has aggregates of good quality at large quantity, this quarry should be made the main source of aggregates supply for the project, with a crushing plant established near the Ring Road, and with a production plan made with careful study of the balance between the estimated volume of aggregates demand and the construction schedule.

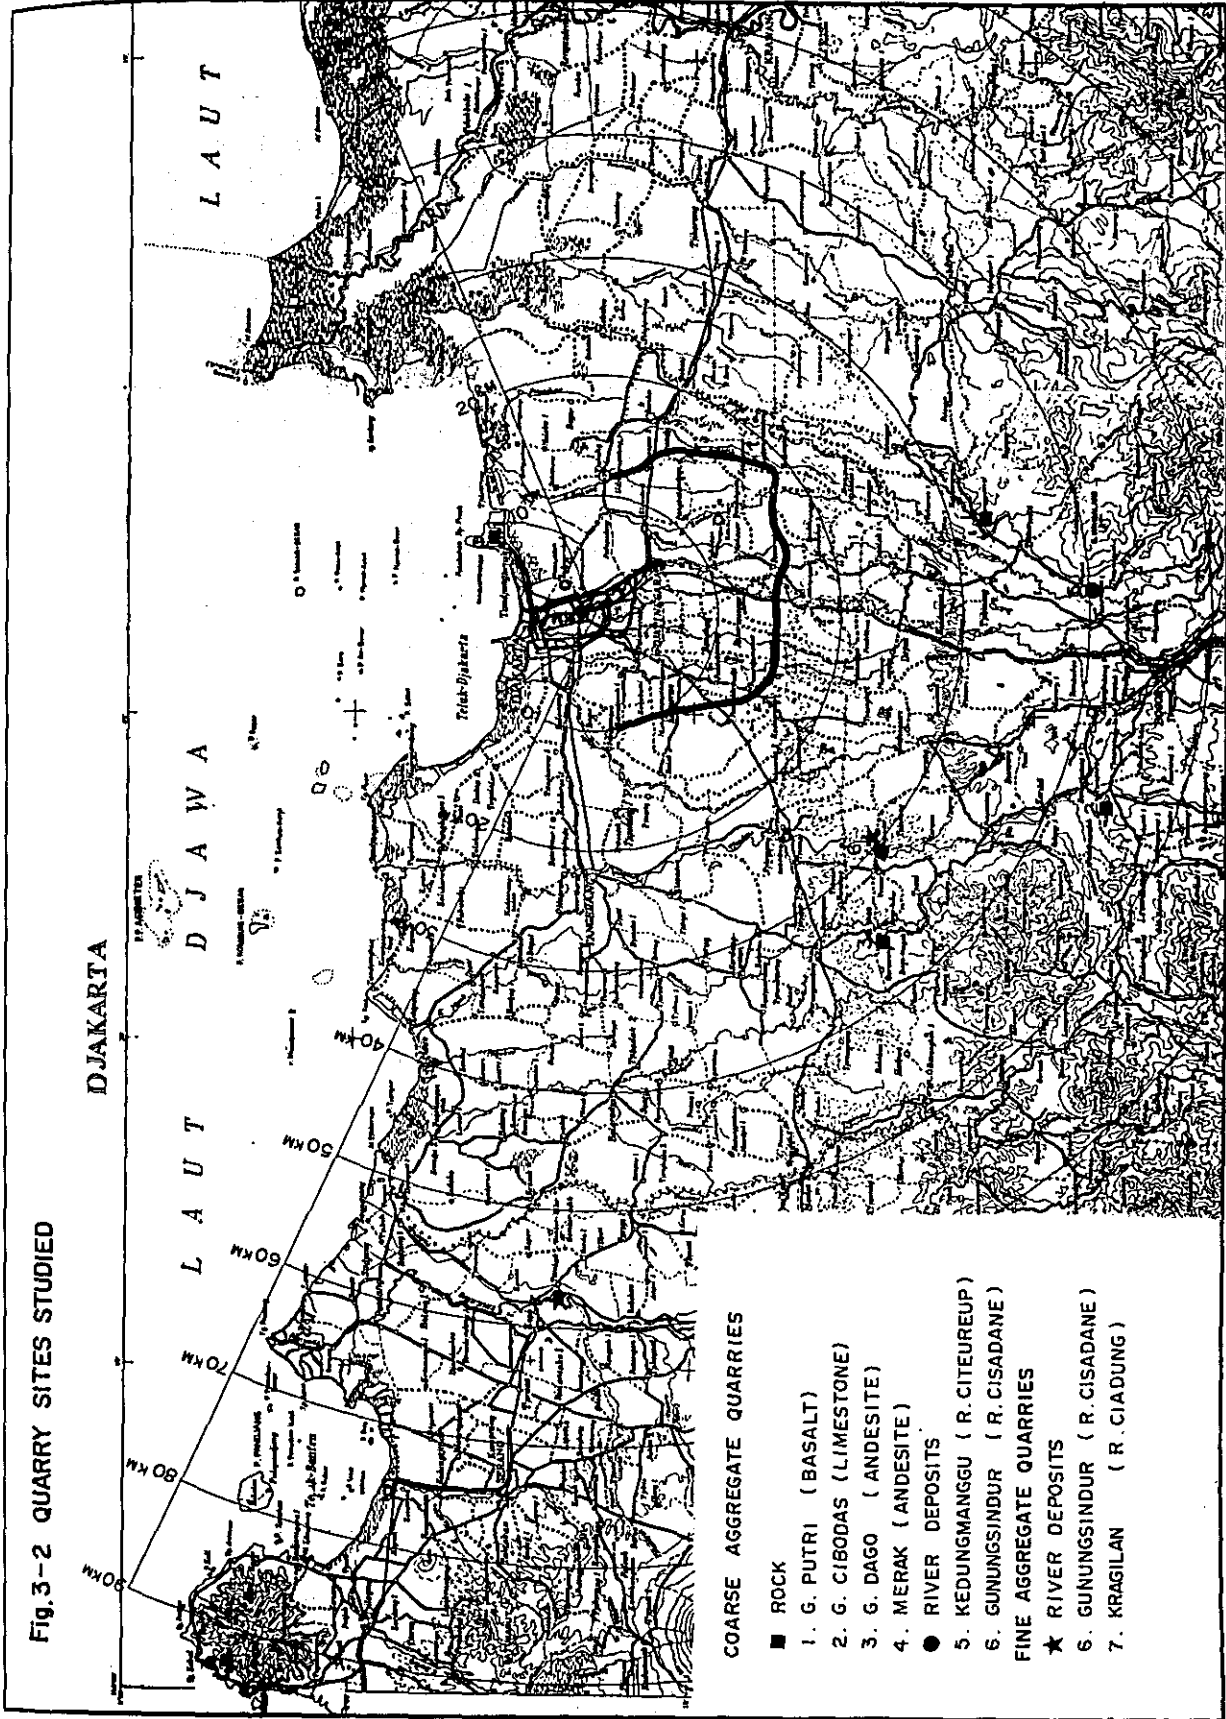

Table 3-6 Summary of Survey of Quarries

| <u>No.</u> | <u>Quarry</u> | <u>Type of material</u> | <u>Remarks</u> |
|------------|---------------|--------------------------------|--|
| 1 | G. Putri | Basalt hill | Quality is fine and hard and there is no problem in material quantity or quality. Mass production is possible with adequate mechanical power. Location is also near the construction site, and is a very highly favored source of aggregates. |
| 2 | G. Cibodas | Limestone hill | Small scale excavation is now being carried out for production of limestone to be burnt to produced lime, but quality is not uniform. Results of abrasion test show that abrasion loss is near the limit for concrete aggregates. Also, there will be problems in production control in case of mass production. |
| 3 | G. Dago | Andesite hill | Top soil is shallow, and little weathering has occurred and the quality is large. As there is no bridge across Ci Sadane, the transport distance from quarry to construction site is very long. |
| 4 | Merak | Andesite and its clastic rocks | This is a well known quarry of the region although it is over 100 km from Jakarta. The quality of the coarse aggregate for concrete is good. But due to the presence of platy joint, care has to be taken in crushing to avoid plate shape aggregates. Mass production is not possible. |
| 5 | Kedung-manggu | Riverbed sediments | This is the quarry site for Jagovawi Highway, where production by crushing of river pebbles is carried out at two or three sites of the Citeureup River. The riverbed pebbles are of andesite of about 25~50 mm in diameter. The pebble layer is about 2~3 m in depth and most of the locations are already exhausted of supply. |
| 6 | Gunung-sindur | Riverbed sediments | Manual excavation is carried out at Ci Sadane River for sand and gravel and the aggregate layer is about 2~3m. |
| 7 | Kargilau | Riverbed sediments | This is the sediment of Ciadjung River at about 60 km west of Jakarta, and small scale excavation is made for sand. Quantity is hopeful. |

Fig. 3-3 Chart of Estimated Aggregates Demand by Year

3-3 River and Hydrological Analysis

3-3-1 Site Surveys

The site surveys are carried out to obtain data for the planning of the bridges of project road, and the design criteria for drainage facilities, and also for the design of the minimum embankment height at river basins and the design of the profile of the highway.

The site surveys were carried out by the study team for a two-month period from March, 1977, making careful studies of the precipitation data of the study area, the basic plan of flood control canals in Jakarta and other existing hydrological data, and also performing detailed field reconnaissance for the areas where the project road are liable to be affected by water.

(1) Rainfall characteristics

The project area is situated at northwest Java, of latitude $6^{\circ}11'$ south and longitude $106^{\circ}50'$ east and the climate shows the typical characteristics of Southeast Asian monsoon zone. The rainfall characteristics shows a distinctive dry season and wet season at half-year interval, due to the effects of tropical seasonal wind. The average annual precipitation at the flat area of the urban area of Jakarta facing the Java sea is about 1,800 mm, whereas at the mountain area towards the upstream of Ciliwung River the figure is more than double to 4,000 mm.

The study area of the project road is located between the flat area and the mountain area and rainfall data for the past 30 years were recorded at over 2,000 mm. 80% of the rainfalls in the 6-month period from November to April of the following year, and rainfall is particularly scarce for July and August which record about 60 mm. Nevertheless, the extreme dry season found in East Java or the Sundura Islands is not experienced here.

The daily characteristics of rainfall is such that the rain comes in the late afternoon or the evening at great intensity for one to two hours in the form of squall to a limited locality. From the rainfall data of the past 100 years from 1864 to 1961, the

maximum precipitation in 24 hours was recorded at 266 mm and the maximum hourly precipitation was 106 mm.

(2) The existing situation of the main rivers

As seen from Fig. 3-4, the major rivers of the study area, such as Pesangrahan and Ciliwung, flow from the southern hill area towards the Java Sea at distances of 2 ~ 5 km from one another. The gradient of flow near the river mouth is generally very gradual and the rivers meander along the way so that the river courses are not very stable. At the flat area of the river basin, inundation through floods extends over wide area, and early steps for river improvement, embankment provision and canal construction for flood control purpose are necessary.

The Ciliwung River towards the east of Jakarta-Depok railway line has a width of about 30 m near the project road, a width of over 100 m upstream and a river basin area of 310 km², is the largest river of the region.

Scouring is observed at the bridge piers of most existing bridges of the rivers, so that in the planning of river crossing, ample consideration has to be given to the location of the bridges and the span of the structure. The results of surveys of the major rivers are as summarized in Table 3-7.

3-3-2 Calculation of Discharge from the Study Area

The volume of discharge of the major rivers extending about 10 km to the south of the planned East-west flood control canal was calculated from the basic plan for the flood control canal of Jakarta prepared in 1973 and other available hydrological data, in order to obtain basic data for the planning of road profile, bridges and drainage structures.

(1) Calculation assumptions

(a) Peak discharge volume

The peak discharge volumes of the rivers were calculated by the rational formula. That is, assuming that the rainfall to an area is at a uniform intensity of YT (mm/hr) for a

Fig.3-4 MAP OF MAJOR RIVERS

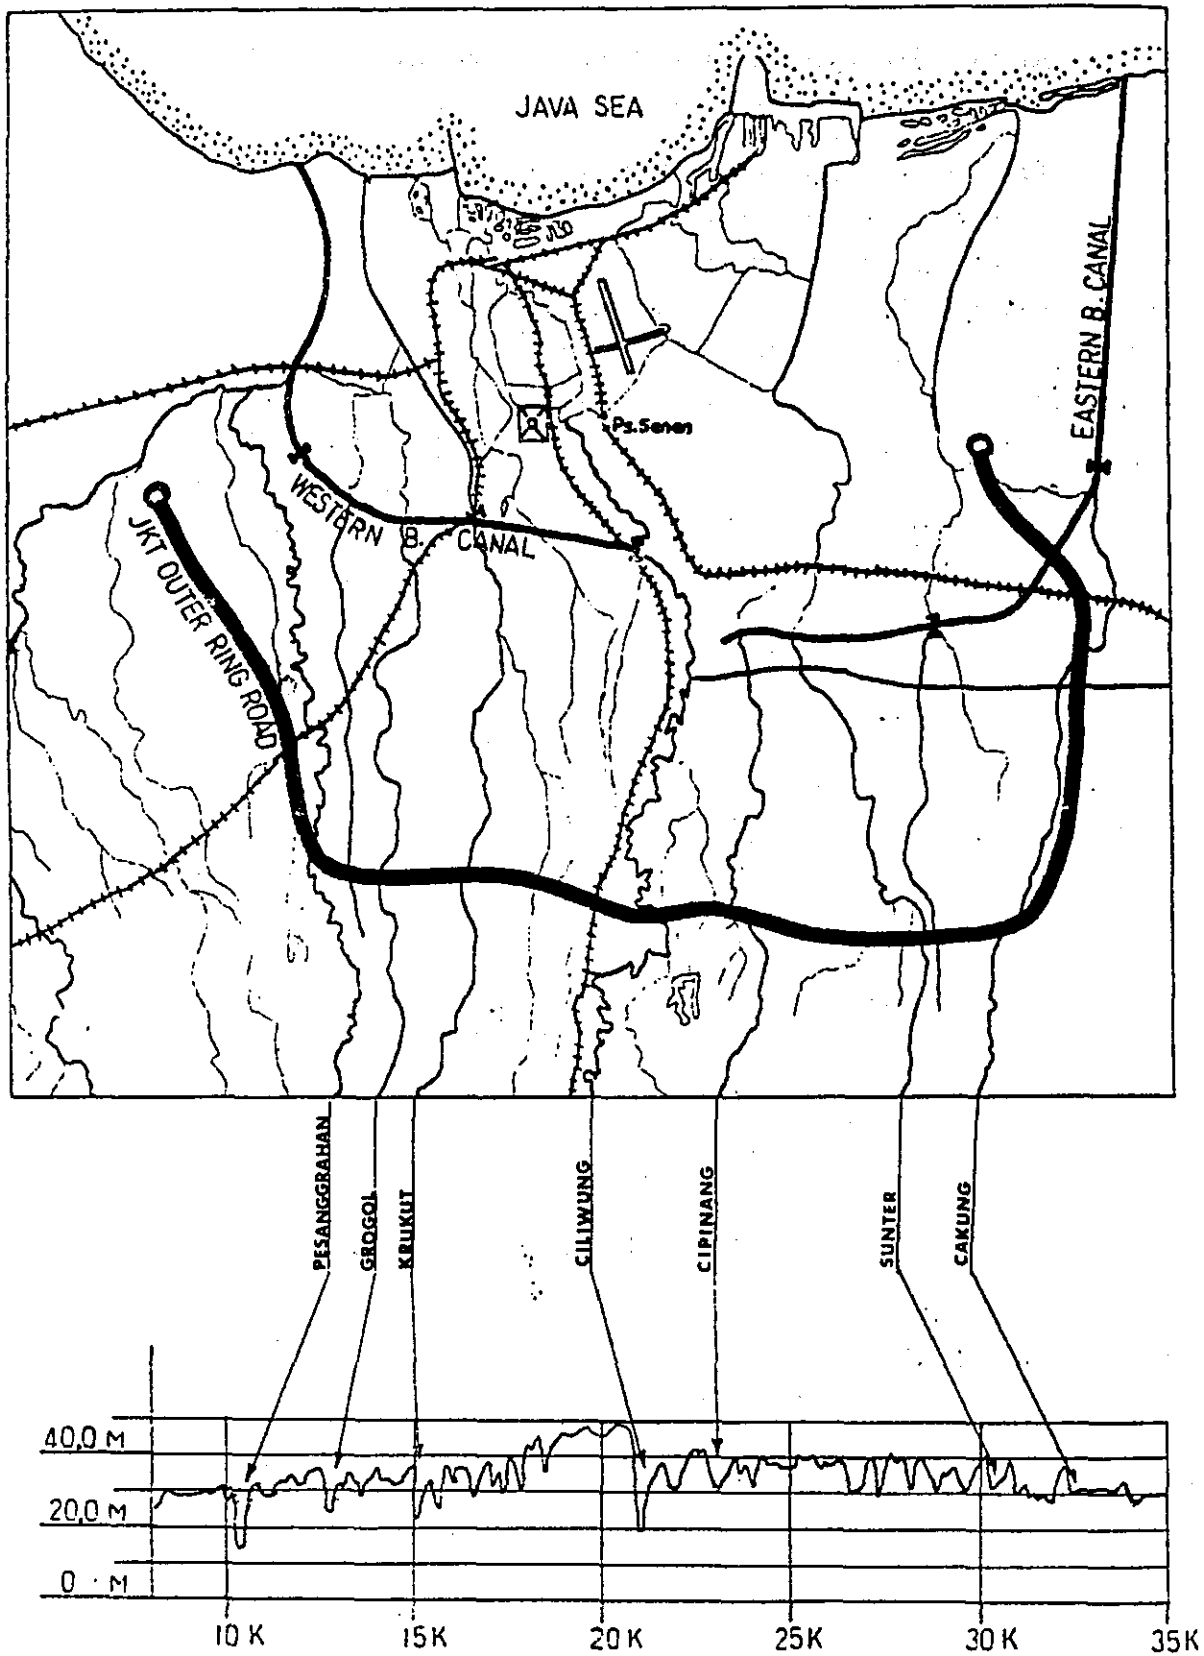

Table 3-7 Main Drainage and Bridge Survey Data

| Name of River | Station | Nearest Village | Discription of Site | | | | Existing Structure |

| S. Cakung | 30 + 750 | Buaran | 10 m | 15 | Silty water | at 0.2 km down stream 6 m span steel beam Bridge | |

duration of T hours, and the arrival time required for the water that falls on the uppermost end of the river to the river basin end (the location of the project road) via the earth surface and the river course is T_c hour, then using the maximum rainfall intensity of Y_{TC} at T = T_c hour, the peak discharge volume Q_p is expressed in the following formula.

$$Q_p = \frac{1}{3.6} \cdot f \cdot Y_{TC} \cdot A \text{ (m}^3/\text{sec)}$$

where: f is discharge coefficient
A is river basin area

(b) Arrival time

The arrival time T_c is calculated with the formula established by Ir. J. H. Haspers taking into consideration the characteristics of rivers in Java.

$$T_c = 0.1 L^{0.8} \cdot i^{-0.3}$$

where: L is length of river
i is gradient of river

(c) Maximum rainfall intensity for T hours

$$Y_T \text{ (mm/hr)} = \frac{R_{24}}{24} \cdot \left(\frac{24}{T}\right)^{2/3}$$

where: T₂₄ is maximum rainfall in 24 hours, using the 266 mm recorded for the mountain area from 1864 to 1961.

For major structures, the rainfall intensity probability is taken as 100 years.

(2) Discharge volume of major rivers

The areas of river basins of major rivers are as shown in Fig. 3-5, and, calculation in accordance with the above mentioned assumptions, the discharge volume of the major rivers and the control height of the project road are computed as shown in Table 3-8.

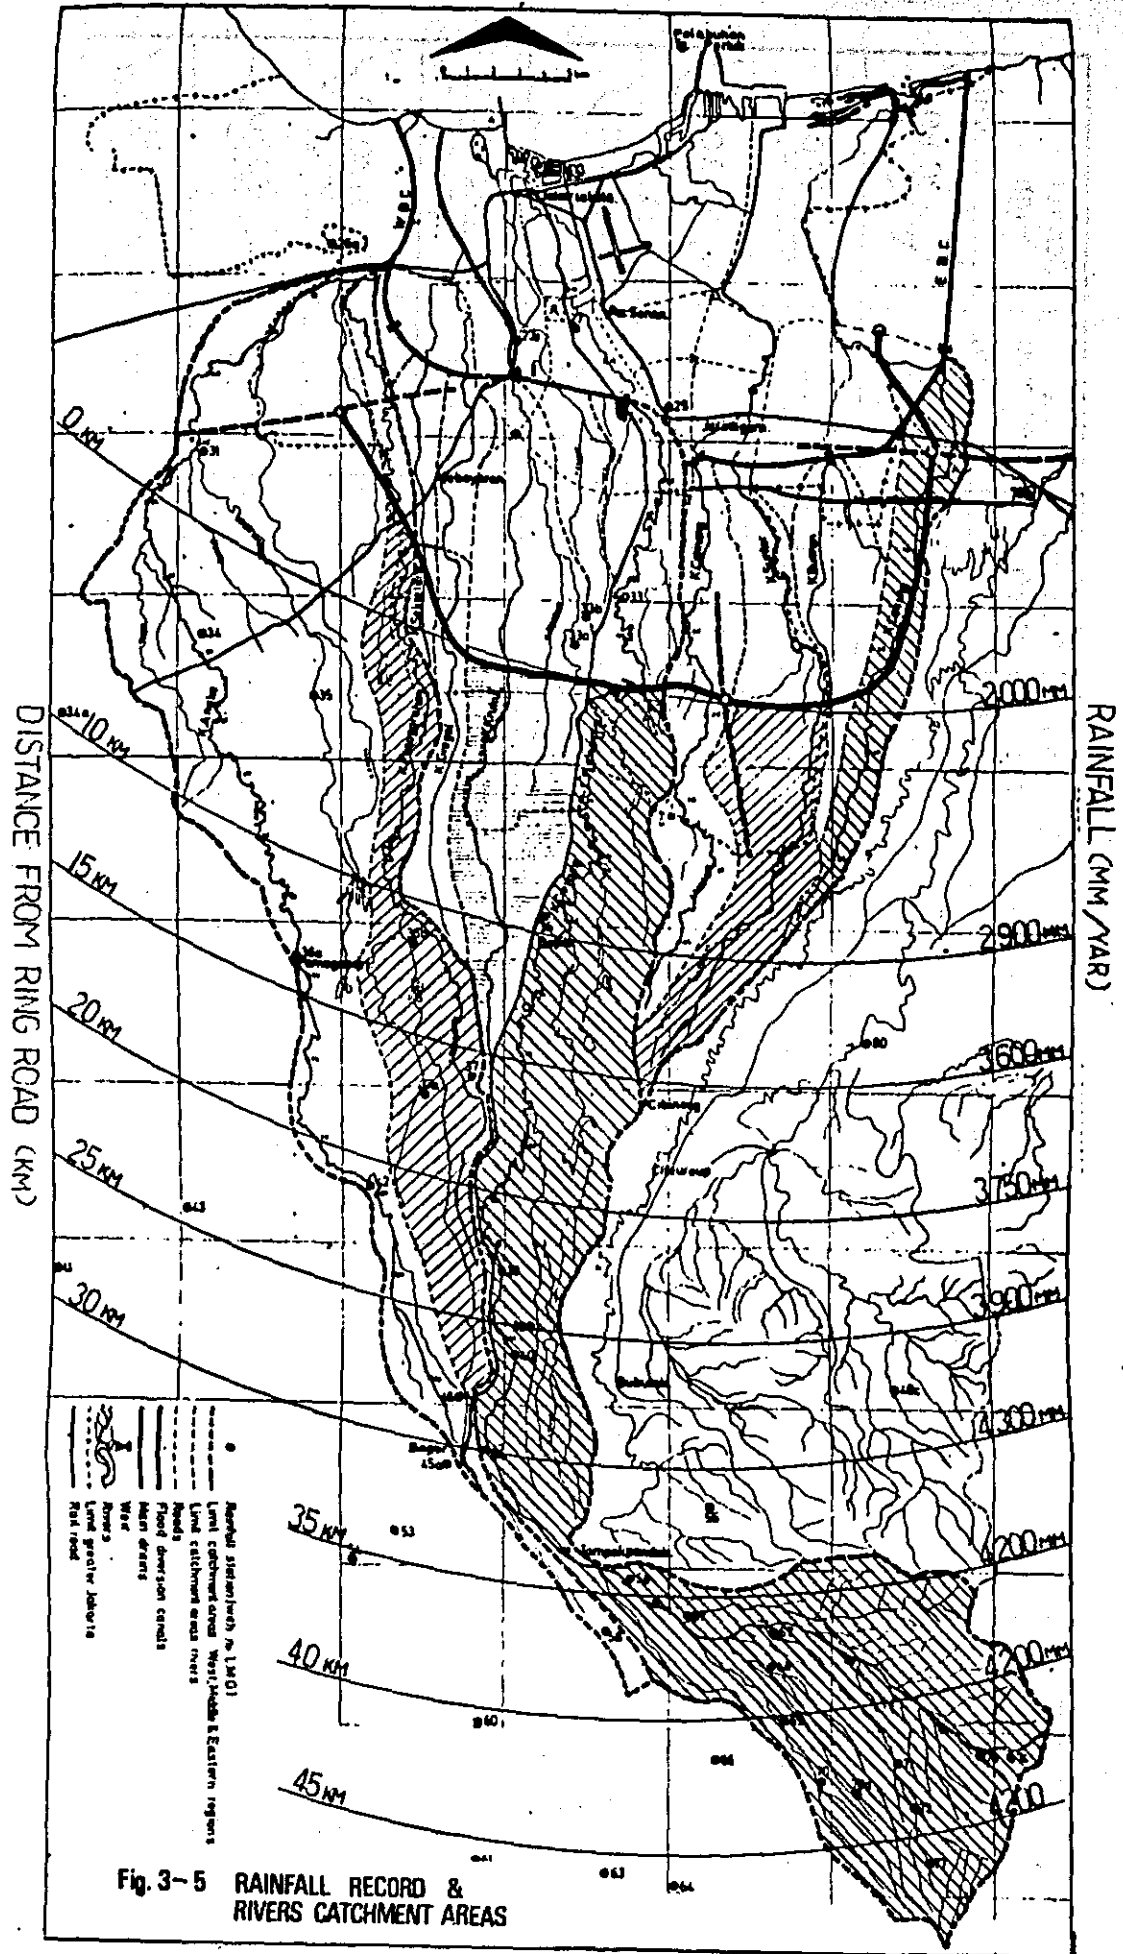

Table 3-8 PEAK DISCHARGE OF MAIN RIVER

| Name of River | Catchment Area (Km ²) | Length (Km) | Altitude (m) | | | Slope (i%) | Concentr. Time (Hr) | Reduct. Coeff. | Peak Discharge (m ³ /s) | Control High (m) |

3-3-3 Planning of Bridges and Road Crossing Drainage Structures

(1) Classification of structures

According to the discharge volumes calculated in the previous section, the size and type of structures adopted for the proposed Ring Road are classified as in Table 3-9. Basically, bridges are planned for rivers with peak discharge Q_p (100) of over 50 m³/sec and the span of the bridges is determined according to the cross section of the river and the planned control height.

Table 3-9 Classification of Structures

| <u>Q_p (100 m³/s)</u> | <u>Structure</u> | <u>Size</u> |
|--|------------------|-----------------|
| 0 ~ 2.5 | Pipe culvert | φ100 |
| 2.5 ~ 5.0 | Multi-pipe C. | 2 ~ φ100 |
| 5.0 ~ 25.0 | Box culvert | 3.00 x 2.50 |
| 25.0 ~ 50.0 | Multi-Box C. | 2 ~ 3.00 x 2.50 |
| 50.0 ~ 200.0 | Bridge | Span 15 ~ 20 m |
| 200.0 ~ | Bridge | Span 30 m ~ |

(2) Planned height of bridge

For river bridges, it is necessary to plan the required clearance from the lower part of the girder to the control height. The following are adopted as the minimum value for the clearance according to the planned discharge volume, thus controlling the planned profile of the project road.

| <u>Q (m³/sec)</u> | <u>Clearance (m)</u> |
|------------------------------|----------------------|
| ~ 100 | 0.6 |
| 100 ~ 500 | 0.8 ~ 1.0 |
| 500 ~ 1,500 | 1.0 ~ 1.2 |

The Ring Road crosses the flood control canal planned by the Jakarta City near Sta. 43. The cross section of the planned canal as shown in the Masterplan for Drainage and Flood Control of Jakarta, 1973, is adopted for the control point for bridge plan.

Fig. 3-6 Cross Section of the Eastern Flood Control Canal

CHAPTER 4 DESIGN CRITERIA AND ALTERNATIVES

4-1 General

The Ring Road project for Jakarta, as shown in the landuse plan in Chapter 2, is part of a program of infrastructure improvement for the purpose of promoting development of various urban functions. The size of the Ring Road is about 14 km in average radius from the urban center, and extends for a distance of about 48 km, connecting the various radial roads at the periphery of Jakarta. The road will form the backbone of future Jakarta, and serve as a defining line for guiding the expansion of building up to prevent sprawling of the city.

In this chapter, a comparative analysis from different angles is made for the main road and the interchanges, which are planned at about 6 km interval, from the points of road maintenance situation and forecast traffic demand in order to obtain a suitable solution so that a policy may be established for the project road economically and technically and that an effective and feasible alternative may be determined.

The guidelines for determination of the route are as shown in Table 4-1 and the relevant items considered in the comparative study of the alternatives are shown in Fig. 4-2.

STUDY ITEMS ON ALTERNATIVES

Fig. 4-2 Relevant Factors for Establishment of Comparative Alternatives

4.2 Design Criteria for Main Route

4-2-1 General

The project road is to be connected to 3 urban toll roads (Jakarta-Tangerang Jagorawi, and Jakarta-Cikampek), either under construction or under plan.

The design criteria of these toll roads are mainly based on the "Expressway Geometric Structure Standard (draft), 1976" by the Bina Marga, Indonesia, the "Highway Geometric Structure Standard, 1970" of Indonesia and the "Highway Structure Ordinance" Japan. For the project road, alternative studies are made for the toll-road alternative and the toll-free-road alternative, and the road has to be planned in coordination with the above-mentioned three toll roads.

For this study, the design criteria adopted or newly established are explained in the following sections.

4-2-2 Geometric Structure Standard

(1) Design speed

For the toll-road alternative, the design speed is set for the two cases of 120 km/h and 100 km/h, and for the toll-free-road alternative, the 100 km/h design speed is adopted.

In the determination of the design speed considering the future important role of the road as an urban ring road, as high a speed as possible is adopted, because the physical features are favourable, and it is possible to construct the road at a high design speed and high capacity at a low construction cost.

For the free-road alternative, which will be a partially access control road, due to the in-and out-flow of traffic from the frontage roads in conformity to the function of the road it is not desirable for the speed to be higher than 100 km/h from the point of safety, and basically the design speed is set at 100 km/h for the whole route, and where unavoidable due to land use of physical conditions, the design speed is dropped to 80 km/h.

(2) Cross section width composition

For the two-direction four-lane section, the traffic lane is set at 3.75 m for both the toll and free road, providing 3.00 m for the left shoulder and 1.50 m for the right shoulder, in accordance with the stipulation of the Indonesian "Expressway Geometric Structure Standard (draft), 1976." The median is set at 113 m, the same as that for Jakarta-Cikampek and Jagorawi Highways. (Please see Fig. 4-3).

A 6-lane section is planned for the free road alternative from IC6 (Sta 17 + 055) to IC9 (Sta 24 + 570) and the cross section width composition is as shown in Fig. 4-3. In this section, the median is 5.50 m, which is of a lower standard than other urban expressways, but the section is short (7.5 km), and the width is in conformity with the minimum width of 5.50 m stipulated in the Indonesian "Expressway Geometric Structure Standard (draft), 1976."

(3) Minimum curve radius

Generally, it is desirable to adopt as large a curvature for the alignment within the limit of the physical feature, and for the project road, since most of the region around the road is flat plain, flatter curve radii are set than the minimum curve radius stipulated by the Indonesian geometric structures standard, and variations are made for the minimum radius to fit the requirements of a maximum superelevation of 8%.

(4) Cross fall

The crown height is determined from the both point of view of surface drainage and traffic safety. For the purpose of surface drainage the crown height should be higher and for the purpose of traffic safety the surface should be flat. From these two kinds of opposite purposes, the gradient of cross fall is determined considering the kinds of vehicles, rainfall, horizontal and vertical alignment and kinds of surface. For this Ring Road study the typical gradient of cross fall is decided 2% from the experimental equation of surface drainage.

(5) Traffic capacity

The traffic capacity is computed based on the Japanese "Highway Structure Ordinance," due to the fact that the various conditions of traffic in Indonesia, such as the type and size of vehicles are very similar to those in Japan. The method of computation of traffic capacity is as shown in Table 4-3.

CD; Design capacity (Veh/hour)

4-3 Design Criteria for Interchange

4-3-1 General

In determining the design criteria, the factors to be taken into consideration are the characteristics of the roads to be connected to, the design speed, traffic volume, and locality conditions. The interchange has to ensure smooth and safe connection between the two roads.

The characteristics of the connected roads are whether it is a toll road or a free road, and from the point of operation of the Ring Road, the factor to be considered is whether the Ring Road is to be operated as a toll road or a free road. The design criteria adopted or newly established under these conditions are described in subsequent sections.

4-3-2 Geometric Structure Standard

(1) Design speed of ramp

(a) Connection with inter-city toll roads

This will be a connection between two expressways, and the ramp will be considered by the drivers as part of the expressway, so that the ramp has to be planned as a converging or diverging section of the expressway. Therefore, generally it is desirable that the design speed of the ramp be the same as that of the main route and the minimum speed should be 1/2 that of the main route. The design speed for each ramp should therefore be determined within this range taking into consideration the traffic volume and the physical features.

The above principles are more easily conformed to in the case of a three-branch interchange. However, when applied to four-branch interchange, the interchange has to be the direct-connection type which involves enormous increase in construction cost. For this reason, the design speed is usually further reduced.

Fig. 4-7 TYPICAL CROSS SECTION OF INTERCHANGE

$V = 40 \text{ km/hr}$ 60 km/hr
SCALE 1:200

Thus taking all the above points into consideration, the design speed for the ramps of interchanges connecting intercity expressways, is set at 60 km/h or 1/2 that of the main route, but for the loop ramps, the exception of 40 km/h is adopted. In the case of the Ring Road being operated as a free-road, considering that vehicles have to stop at the toll gate installed in the interchange, the design speed is set at 40 km/h for all ramps.

(b) Connection with ordinary roads

Considering the design speed of the Ring Road (120 km/h), the design speed for ordinary roads (60 km/h), the traffic volume of the interchanges, and the necessity of installing toll gates, the design speed of ramps is set at 40 km/h. However, care is taken to ensure safety at the diverging point from the ramp to the main route for both the inflow and outflow traffic.

(2) Width composition

The width composition for ramps of single direction single lane type, two direction two lane type and also for the zone are in conformity with the standard adopted for the Jakarta-Tangerang Highway. For the single direction two lane ramps although the standard of 3.80 m per lane is stipulated in the Expressway Geometric Structure Standard of Bina Marga, the width of 37.5 m is adopted.

The width composition of the ramps is as shown in Fig. 4-7 and the items studies are summarized in Table 4-4.

4-3-4 Traffic Capacity

The traffic capacity is computed based on the Road Structure Ordinance of Japan, for the same reason as in the case of the main route.

The design traffic capacity for a single lane ramp, is 1,200 pcu/hr, since the curvature, gradient, and vertical curve of the ramps are of a lower standard when compared to the main route,

Table 4-4 INTERCHANGE GEOMETRIC DESIGN STANDARD FOR RAMP WAY

Note; 1) Vertical curve length at ramp side will be used as shown in Fig. 4-4, 4-5 (V = 60 km/h)

but consideration is given for the reduction in capacity due to heavy vehicles. (A heavy vehicle composition of 10% will reduce the design traffic capacity to 88%).

Since the capacity of the ramp is usually much smaller at the connecting point with the main route when compared to the capacity of the ramp itself, the practical traffic capacity of the ramp is determined by the capacity at the connecting point. The method of calculation for this connecting point is based on the formula in Highway Capacity Manual (U.S.A. 1975).

4-3-4 Toll Gate

In the planning and design of the toll gate, considerations have to be made regarding the road, topographical and other conditions as well as the system for the control and operation of the road. That is, in determining the type of interchange for a toll road, the system of toll collection has to be studied at the same time. The following items are studied based on the Design Manual, Vol. 4 of Japan Expressway Public Corporation.

(1) Toll system

The toll system for a toll road may be generally divided into uniform toll rate and sectional toll rate systems. Fig. 4-8 gives an illustrative example of the above two systems.

(2) The determination of the number of traffic lanes at a toll gate.

The number of traffic lanes to be provided at a toll gate is determined from the traffic volume (interval of arrival), the service time per vehicle, and also the service level provided (planned length of waiting queue).

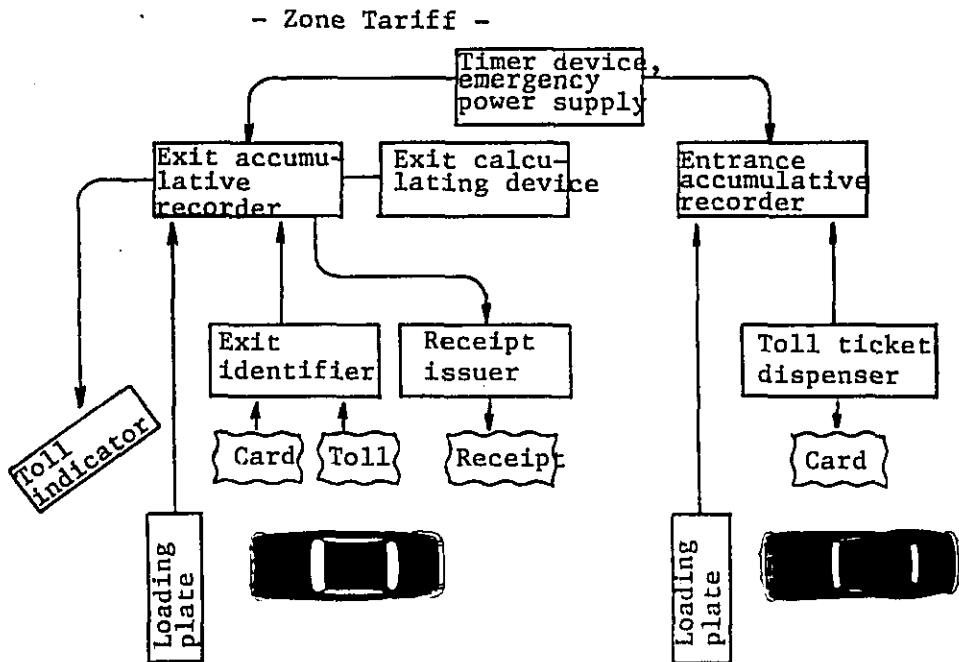

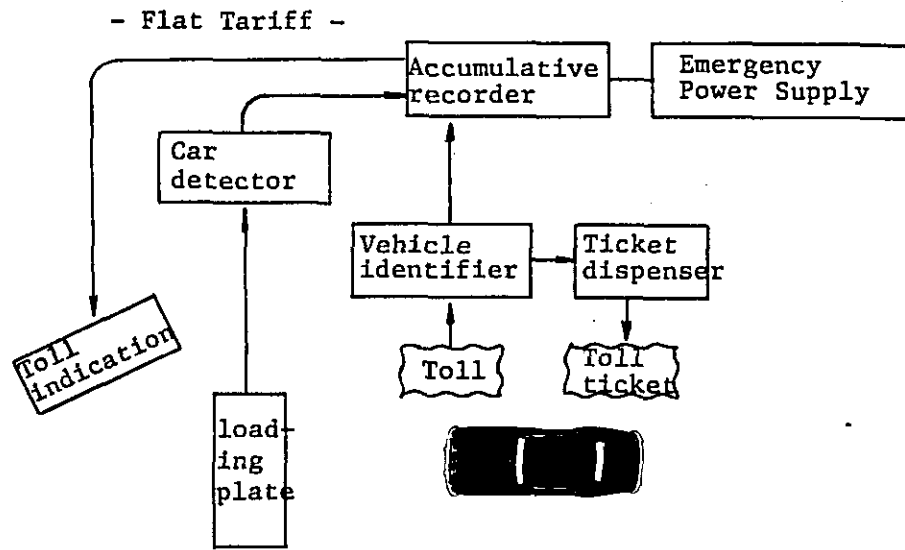

The above factors are decided according to the following standard.

(a) Basic hourly traffic volume

The basic traffic volume used is the design hourly traffic volume (DHV) which is calculated from the average daily traffic volume (ADT) by the following formula.

$$DHV = ADT \times K \times D$$

Fig.4-8 Example of Composition of Toll Collection System

In the above formula, the coefficient K (peak hour rate) is taken as 8% and D (single direction concentration of traffic) is taken as 60%.

(b) Service time per vehicle

The service time is assumed at 6 seconds for one entry and 14 seconds for one exit in the case of sectional toll rate and 8 seconds for all vehicles in the case of uniform toll rate, for the purpose of calculating the required traffic lane at toll gate.

(c) Service level

The service level is expressed in term of the length of the waiting queue and in principle there should be no vehicles waiting at a queue.

Based on the above assumptions, the calculation results are as shown in Table 4-6.

Table 4-6 Hourly Traffic Volume and Traffic Lanes
(Capacity of handling in one hour)

| No. of traffic lanes | Average service time(sec) | | |
|----------------------|---------------------------|-------|-------|
| | 6 | 8 | 14 |
| 1 | 300 | 225 | 128 |
| 2 | 852 | 638 | 364 |
| 3 | 1,422 | 1,065 | 609 |
| 4 | 1,922 | 1,492 | 852 |
| 5 | 2,580 | 1,935 | 1,105 |
| 6 | 3,168 | 2,376 | 1,356 |
| 7 | 3,780 | 2,835 | 1,617 |
| 8 | 4,368 | 3,272 | 1,872 |

(3) Criteria for planning and determination of toll plaza facilities.

(a) Target year for calculation of facilities

The toll plaza facilities to be provided in the year of opening are as follows:

Table 4-7 Installation Criteria of Facilities

| <u>Facility</u> | <u>Target year</u> |
|---|------------------------|
| Land for toll plaza | 20 years after opening |
| Earthworks of toll plaza toll island, traffic lane pavement toll plaza building | 10 years after opening |
| Toll booth and cash receiving machine | 5 years after opening |

(b) Geometric structure standard of toll plaza

- 1) The width composition is as shown in Fig. 4-10.
- 2) Even if only one lane is required from calculation, two lanes will be provided with the left lanes serving as reserve lane.
- 3) The size of toll island will be 22.4 m in length, 2.2 m in width and 0.15 m in height.
- 4) The horizontal alignment at the portion where the toll plaza is to be provided will in principle conform with that for the main route and the minimum curvature radius at a interchange toll gate is 200 m.
- 5) The vertical curve of the portion where toll plaza is to be provided will be based on the criteria for the main route and that for the interchange toll gate will be more than 8,000 m in principle and more than 7,000 for exceptions.
- 6) The vertical gradient for a toll gate area is below 2% in principle or below 3% for exceptions. The range to be governed by this standard will be 100 m both sides of the gate in the case of toll gate on the main route and 50 m on both sides in the case of the interchange toll gate.
- 7) The standard cross fall at a toll gate is 1.5% and the maximum is 2.0%.
- 8) The toll gate portion will be 7 cement concrete pavement and the range is 50 m on both sides of a gate for

main route toll gate and 25 m on both sides of a gate for interchange toll gate.

- 9) The cement concrete portion will be of the same width as that required at the toll gate center line and the standard easement at both ends will be as shown in Fig. 4-9, but particular attention will be paid to the aesthetical effect. As shown in Fig. 4-9, the easement rate S.L. will be below 1:3 and will be so planned as to enable smooth traffic flow.

Fig. 4-9 Easement at Toll Gate

- 10) At an interchange toll gate, the distance from the center line of the toll gate to the diverging point of the ramp should be over 75 m.

4-3-5 Interval of Interchange

To determine the location of interchanges, the study for the interval of interchanges is done from the viewpoint of traffic safety. For this purpose, two points are examined. One is whether it is possible to allocate the necessary traffic signs to guide the traffic safely. The other is whether it is possible to treat the weaving traffic safely.

Generally, the necessary distance for the allocation of the traffic signs is longer than that for the weaving traffic. It is sufficient for the traffic safety if it is possible to get the necessary interval for the signs' allocation.

Fig.4-10

TYPICAL CROSS SECTION OF TOLL PLAZA

S = 1 : 200 (Meter)

CLEARANCE OF TOLL LANE

S = 1 : 100 (Meter)

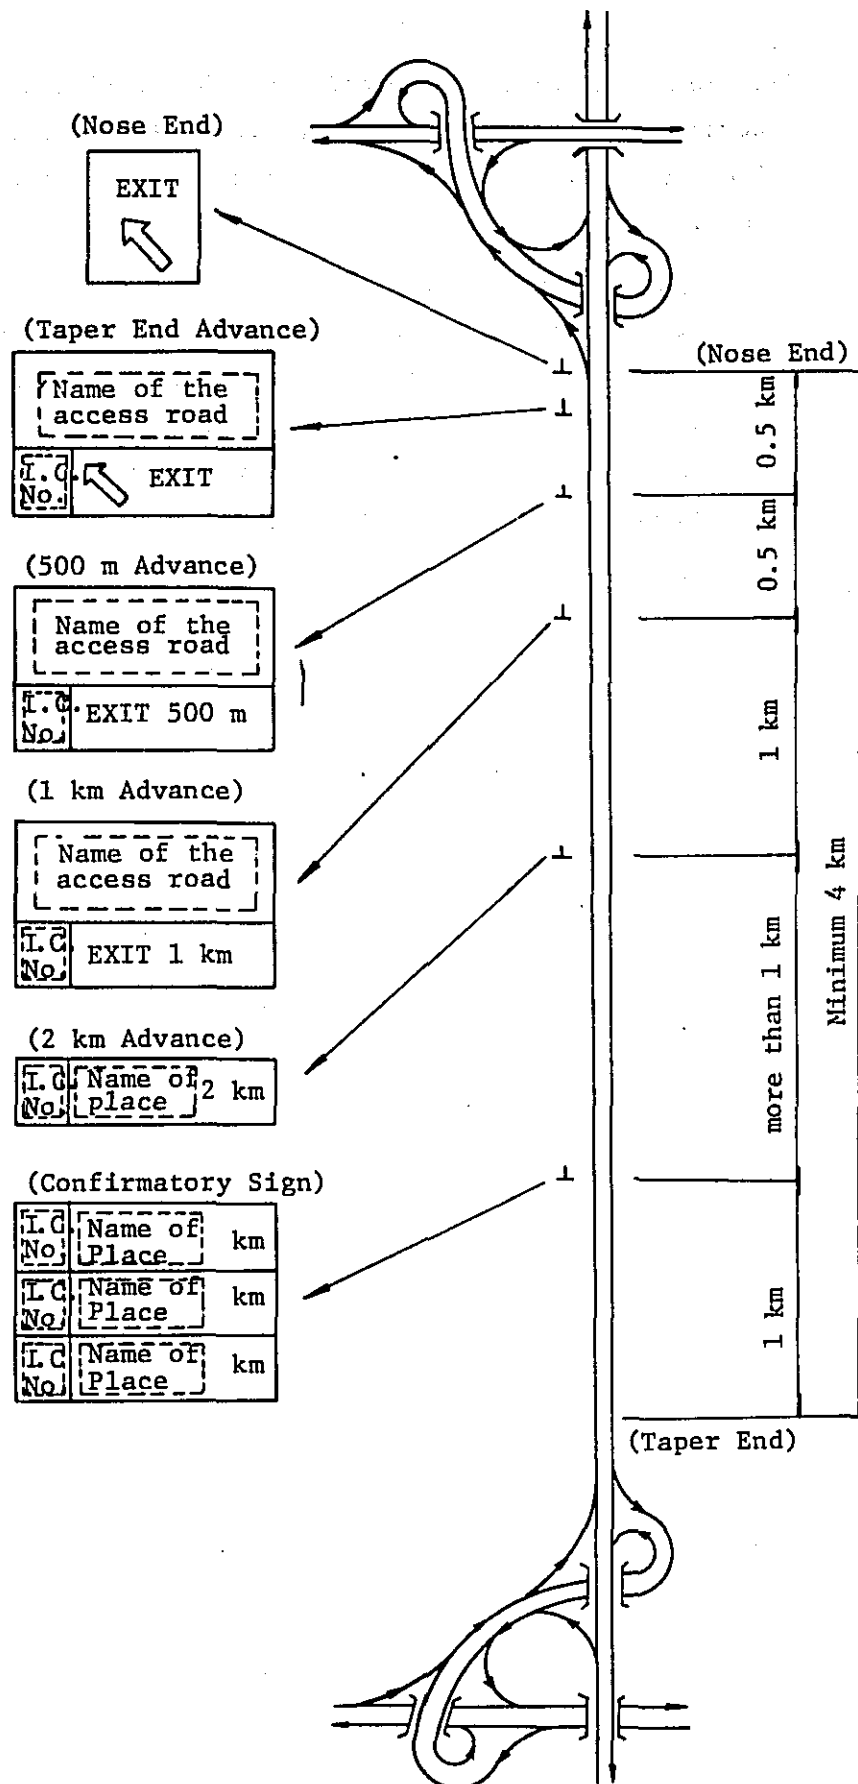

Fig. 4-11 ARRANGEMENT OF THE TRAFFIC SIGN

(1) Interval for the allocation of the traffic signs

Generally, on the expressway, the following traffic signs are allocated for the safety of in and out traffic for the interchange.

(a) Signs for confirmation

This sign makes the driver from an interchange to the throughway to confirm his running direction and distance. This is allocated at the 1 km point from the edge of acceleration taper and in case of the interval of interchanges being less than 5 km, this can be avoided.

(b) Preannouncing exit signs

This sign shows the interchange number, name, names of influenced towns and distance. Fundamentally this sign is composed of six signs as shown in Fig. 4-11.

In order to allocate these signs, the interval of interchanges is calculated as follows:

Interval of Interchange

- = Necessary distance for allocation of Preannouncing Signs (2 km)
- + Necessary distance for allocation of Confirming Signs (1 km)
- + Necessary distance for sight of signs (1 km)
- + Average interval between the edge of taper or nose and the center of interchange (1 km)

(2) Weaving section length

According to Highway Capacity Manual (U.S.A.), length of a weaving section is shown and calculated in relation with the traffic volume in Fig. 4-12 and Fig. 4-13.

Fig. 4-12

Fig. 4-13

Table 4-8 Minimum Distance for Weaving

| Weaving Traffic (PCU) | Service Level | I | II | III |
|-----------------------|---------------|-------|-------|-------|
| | 500 veh/h | | 300 | 200 m |
| 1,000 " | | 800 | 400 | 150 |
| 1,500 " | | 1,200 | 650 | 280 |
| 2,000 " | | 1,800 | 900 | 520 |
| 2,500 " | | 2,400 | 1,200 | 600 |

Resultantly, from the viewpoint of weaving traffic, the interval of interchanges should be longer than above-mentioned minimum distance by one kilometers.

Fig. 4-14 Categorize Graph

Fig. 4-15 At Grade Intersection

Number of lanes for the weaving section will be calculated by the following equation.

$$N = \frac{V + (k - 1) Vw_2}{SV}$$

where, N : Number of lanes
Vw₂ : Less traffic of weaving
V : Total traffic volume
SV : Traffic capacity per lane
k : Factor

4-3-6 Stage Construction for the Interchange with Surface Road

The following figure (Fig. 4-14) shows the necessary point for grade separation by the forecasted traffic volume for 10 years after opening.

4-3-7 Traffic Capacity of Diamond Type Interchange

Traffic capacity of a diamond type interchange is shown in Fig. 4-16. Fundamentally, when the forecasted traffic for 20 years after opening comes into the category B, other types such as a double trumpet type, a cloverleaf type and etc., should be considered to be possible to make a grade separated intersection.

Fig. 4-16 Traffic Capacity of a Diamond Type Interchange

Fig. 4-17 At Grade Intersection

4.4 Analysis on the Number of Traffic Lanes

The required number of traffic lanes is determined from equation 4-1 and the fractional values are rounded up to the higher figure. However, if the fraction is very small, considering that both the design basic traffic capacity and the design traffic volume are approximate values, the factors for calculation of the design basic traffic capacity, the characteristics of the project road whereby stage expansion is possible, the traffic lane may be determined by cutting off the fraction.

$$\text{Required traffic lane (one direction)} = \frac{\text{Planned traffic volume(veh/day)} \times \text{one direction concentration rate(50\%)}}{\text{Design basic traffic capacity (19,000 veh/day)}}$$

(equation 4-1)

The resulting required number of traffic lanes for the Ring Road are shown in Fig. 4-18. In the case of free road, blocks 4 and 5 will be expanded to 3 lanes in each direction in 1995, 10 years after opening, and for all other sections, it will be 2 lanes in each directions.

Fig. 4-18 Traffic Flow Volume by Segment

4-5 Comparative Studies on the Planning of the Main Route

4-5-1 Comparison on the Three-dimension Alignment

(1) Horizontal alignment plan

The control points are the points which form restrictions limiting the route that the road can be pass from technical and social points. As described in section 4-1, the control points are to be in accord with the importance and character of the Ring Road and they cover topographical and geological factors, as well as technical, economic and social environmental factors such as public facilities, cultural treasury, etc. Also some pilot plan on the project road has already been made by the Jakarta City and Bina Marga, and the restrictions that effect the local conditions have also to be adhered to.

- (a) The alignment has to be established within a corridor of 500 m in width stipulated by Bina Marga.
- (b) Of the major radial roads that interesect with the Ring Road, the locations of interchanges with the Jagorawi Highway and Jl. Bekasi are predetermined.
- (c) The route has to be kept at least 500 m away from the military facilities at Jl Hankam.
- (d) Where land acquisition is completed, the alignment has to be planned within the acquired level.
- (e) The regions where developments have been planned and approved by Jakarta City have to be avoided.

Based on the above control points, the route location is made with consideration on the balance of earth work and also workability, and the result is that although these are several local comparative alternatives at the middle of the Ring Road near Ciliwang River, on the whole these are not many comparative alternatives for the entire route. Therefore only one alternative is established for the horizontal alignment plan.

Two alternatives in design speed of 120 km/h and 100 km/h are set from the points of the character and importance of the project road, the planned traffic volume, the situation in access control

Fig. 4 - 19 FLOOD AREA IN THE PROJECT AREA

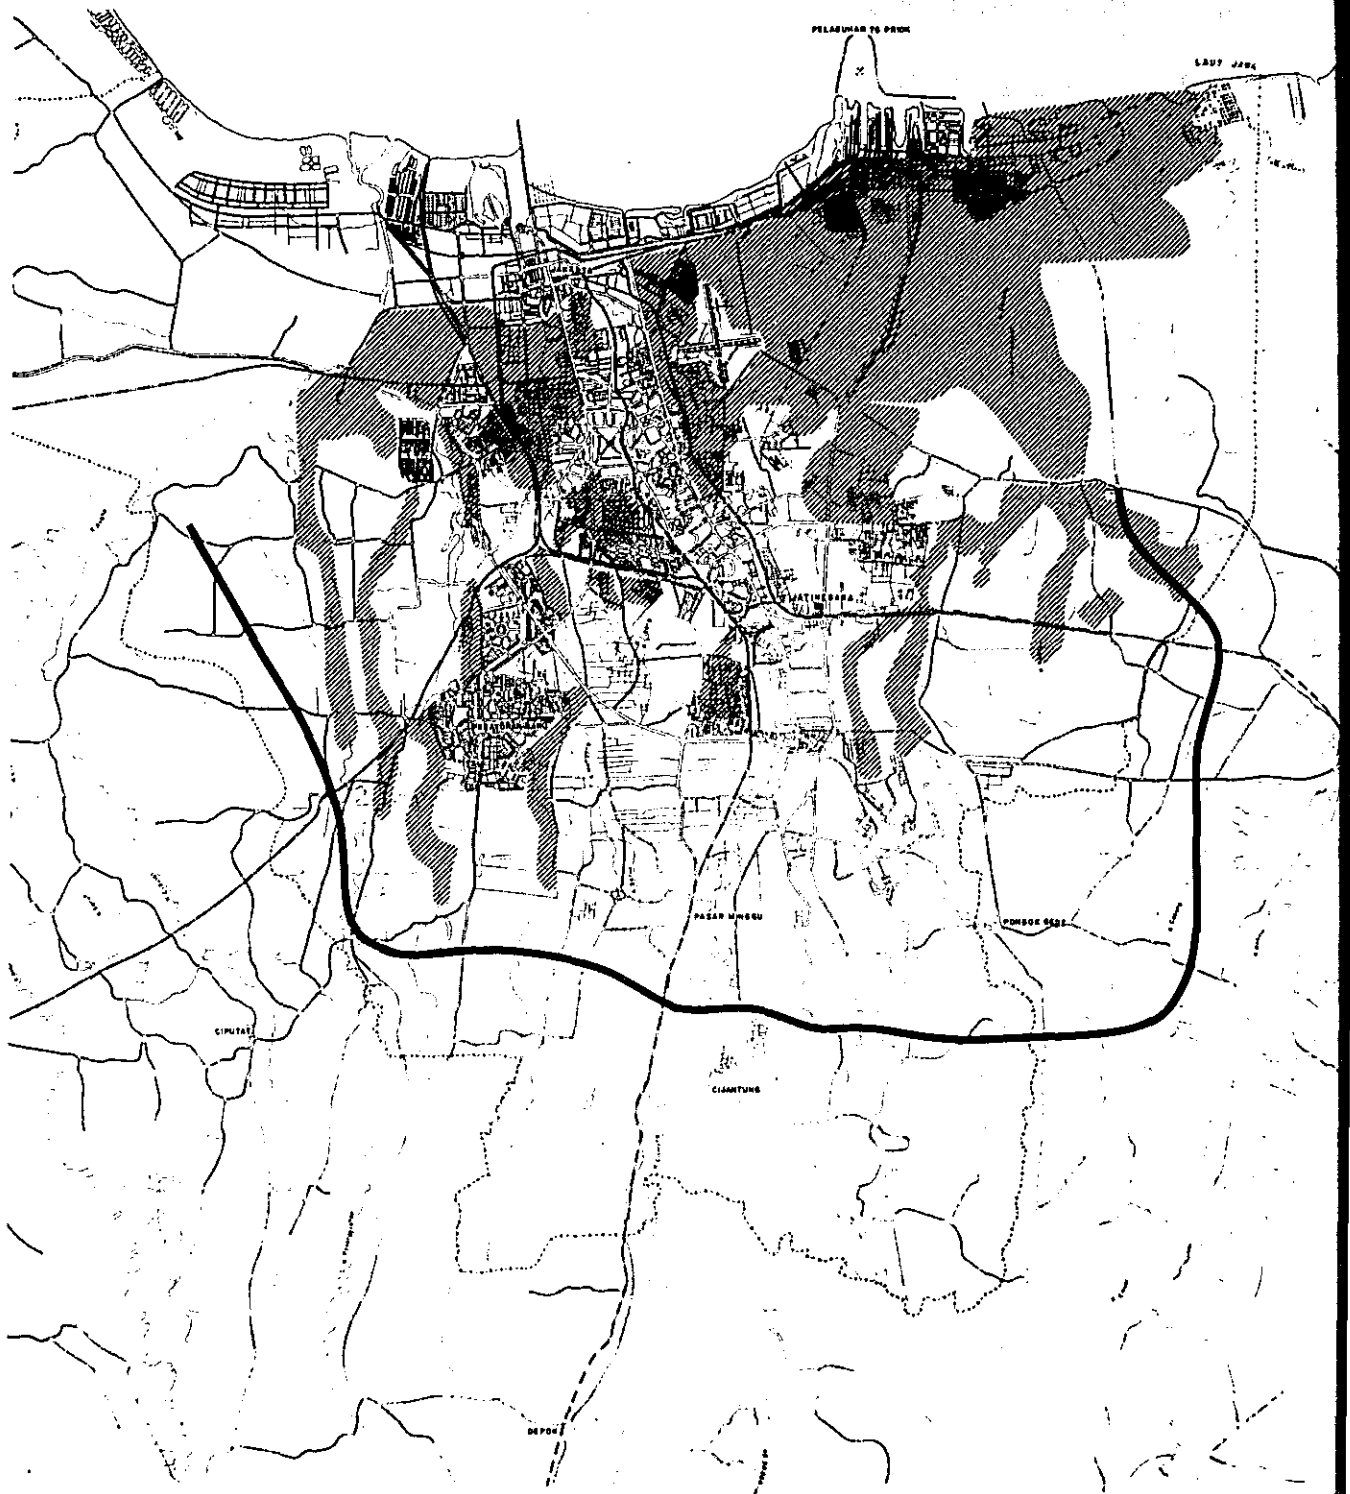

Fig. 4-20 ALLUVIUM AREA IN THE PROJECT AREA

□ Alluvium area

and the topography of the locality. However, since at the section where the road traverses builtups areas, it is planned to have alternating embankment and cut sections, and also since from the point of coordination of the interchanges, the horizontal curve radius is so flexibly planned as not to be rigidly in conformity with the minimum design standard, the design speed factor is not taken into consideration in horizontal alignment plan.

The outline of the alignment is described in Chapter 6, Section 6-2.

(2) Profile planning

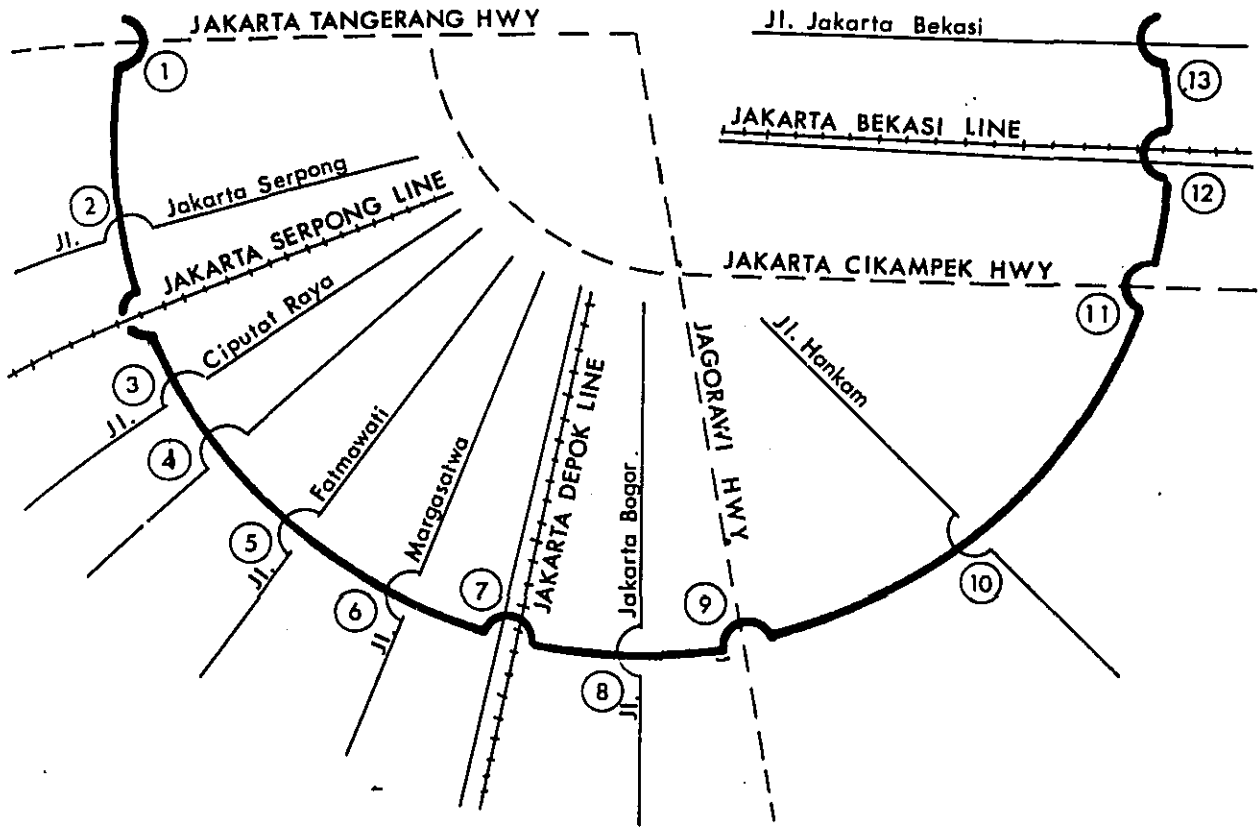

The topography for the project area is such that the hilly area to the right bank of Diliwang River which is now the middle of the project road, is highest in elevation (G.L. = 50 m) and the difference in elevation with the coastal plain at the two ends of the route (G.L. = 3.0 m) is about 47 m. As the road runs in a curve from the coastal plain to the hilly area, the vertical gradient of the route is on the whole very gradual.

In the comparative study of the vertical alignment, due to the fact that basically the minimum vertical curve for a section between two interchanges is affected by the difference in design speed, and that the overall balance of earthwork volume is also affected, comparison is made of the two alternatives in design speed of 120 km/h and 100 km/h.

As for study of vertical alignment at railway crossings, since the future development plan on railway is not know, it is so planned that the alignment of the railway will not be altered in order to maintain future coordination, and alternatives are studied for the cases of the Ring Road overpassing or underpassing the railway. For crossing with inter-city toll highways and other ordinary radial roads, the method of grade separation is determined from the point of suitability of the type of interchange to be adopted. The reduction of embankment and cut volume as well as the volume of borrow earth will favorably effect the construction cost and construction time required so that particularly at railway and road crossings, the vertical alignment

Fig.4-21

GRADE SEPARATION METHOD AT THE CROSSING POINT WITH THE RADIAL ROADS AND RAILWAYS.

-  RING ROAD
-  RAILWAY
-  TOLL ROAD
-  MAIN ROAD

LEGEND

is so determined that where there are no problems regarding drainage and ancillary maintenance works, the balance in earthwork volume is given top priority. Comparison on earthwork volume is carried out by computer by the earth volume curve for the whole route, selecting the most favorable crossing system at crossings and studying on the alternatives of 120 km/h and 100 km/h in design speed.

4-5-2 Alternative Studies on Method of Implementation

(1) General

The construction of an expressway requires very large investment due to various design requirements. For this reason, to obtain maximum economy it is desirable to study the alternative of stage construction to meet traffic demand at various stages instead of completing the final requirement from the beginning.

Stage construction may largely be divided into stage construction of the cross section by varying the traffic lanes and profile stage construction by deferring some construction sections. And there come four alternatives of stage construction as shown in the following to be studied.

- 1) Tollway 4 lanes 2 stages 2 segments
- 2) Tollway Initial 2 lanes 2 stages 3 segments
- 3) Tollway Initial 2 lanes 3 stages 3 segments
- 4) Toll free 4 lanes Initial 2 stages 2 segments

In the following the summary of each alternative is described.

(2) Tollway 4 lanes 2 stages construction

As the initial construction, western segment, 26 km is constructed to meet the traffic demand and the second construction, the eastern segment, 22 km is constructed by four lanes from the opening day.

(3) Freeway 4 lanes 2 stages construction

As described in Section 4-4 above, the planned future traffic lanes requirement for the project road in the case of a free road, a part of the western section will require 6 lanes in 1995, or 10 years after opening. It is therefore desirable to carry out the

Fig. 4-22 Different Methods of Stage Construction

As for bridge the expansion will involve addition to the completed bridge so taht it is difficult to determine an economic type of bridge for expansion. Therefore from the point of ease in construction rather than economy, it is proposed that the bridge be constructed at 6 lanes from the beginning.

construction of this section in pace with traffic requirement by construction of 4 lanes in the initial stage and expanding to 6 lanes in the future.

As seen in Fig. 4-22, in the case of stage construction of traffic lanes, there are three different methods available, namely (A) Construction of the initial 4 lanes from the outer side, (B) Construction of the initial 4 lanes from the inside, and (C) Construction of 3 traffic lanes on the side and using the three lane cross section to temporarily serve 4 lane requirement.

(4) Initial two lane stage construction

This stage construction can save the initial investment cost and can meet the traffic demand by many stages. The conditions for design are as follows:

- Tollway
- Distance proportional tariff
- 120 km/h of design speed
- Segment division

1) Western segment (12.3 km)

Jakarta - Tangerang Highway (IC-1) - Jl. Ciputat Raya (IC-3)

2) Southern Segment (13.85 km)

Jl. Ciputat Raya (IC-3) - Jagorawi Highway (IC-9)

3) Eastern Segment (22.05 km)

Jagorawi Highway (IC-9) - Jl. Jakarta-Bekasi (IC-13)

- Sequence of Segments

1) Two stage method

initial stage; southern segment, 2 lanes

second stage; southern additional 2 lanes

2) Three stage method

initial stage southern segment, 2 lanes

second stage southern segment additional 2 lanes,
and western and eastern segment 2 lanes.

Third stage western and eastern segment additional
2 lanes.

FIG. 4-23 DESIGN DAILY TRAFFIC VOLUME & STAGE CONSTRUCTION SEQUENCE

~ Others

- 1) Initial 2 lanes will be constructed for the 2 lanes of inside of typical cross section.
- 2) Earthwork will be done for the ultimate stage.
- 3) The bridges for the through way will be constructed for initial 2 lanes.
- 4) Box and pipe culverts, over bridges and etc., will be constructed for the ultimated stage.
- 5) Construction of Interchanges will be done for two stages considering the traffic demand.
- 6) For the operation of initial 2 lanes, there should be needed some special consideration and study.

(5) Pavement

In the comparative analysis on pavement, studies are made on the case of providing from the beginning the pavement required to bear the traffic load throughout the entire project period and that of stage construction by making overlay at a subsequent stage.

After analysis of the results of the annual planned traffic volume based on the "ASSHO Interim Guide for Design of Pavement Structure" for the design of the pavement, it is proposed that the surface pavement layer of asphalt concrete at the initial stage be 5 cm thick and an overlay of 10 cm made 10 years after opening of the road. This stage construction will reduce the initial investment by 20%. The method has also the advantage that in case the future traffic growth deviates from the forecast, the final construction may be adjusted to suit the actual traffic situation.

4-6 Comparative Alternatives on Interchange

4-6-1 General

The type of interchange will differ according to the method of operation (toll road or free road), toll system (uniform toll rate or sectional toll rate), and the characteristics of the connecting road (inter-city toll road or ordinary road). Comparative analysis will have to take into consideration the traffic volume, topography, comfort, safety, geometric structure of each type of interchange and economy before a decision can be made on the most suitable type.

The possible types of connection with an inter-city toll road in case that the Ring Road is also a toll road are the turbine type, clover type, double trumpet type, etc. Of these, the turbine type is generally favorable since both the inter-city toll road and the Ring Road will be with a high design speed of 120 km/h or 100 km/h so that it is undesirable to reduce the design speed of the ramp to below 60 km/h (half that of the main route). However, if there is a great difference in the traffic volume by directions, it is more economical to adopt the modified clover type with a provision of a direct connecting ramp (design speed: 60 km/h) for the direction of heavy traffic. In this case, from the points of detour distance, land area, etc., for the right turning traffic, the limit of curve radius of the ramp is 80 m and the design speed of the loop is set at 40 km/h.

In the case of the Ring Road being a free road, the type to be adopted will be the double trumpet type from the point of toll collection for the inter-city toll road. It will be difficult to provide the toll gate for other types.

As for connection with ordinary roads, where traffic can be handled by level crossing with the ordinary road, the possible types of interchanges are the diamond type, single trumpet type, incomplete clover type, etc. Of these alternatives, the diamond type will require dispersal of the toll gates (two gates for uniform toll rate system and 4 gates for sectional toll rate system). However, the construction cost is very low and safety

in high so that on overall evaluation, the diamond type is the most desirable type. For the same reason, the diamond type is also suitable when the Ring Road is a free road.

When the Ring Road is a toll road and grade separation with the connecting road is necessary, from the point of toll collection, the double trumpet type is a suitable type. If the Ring Road is a free road, the possible type will be the double trumpet type and the clover type from the points of traffic volume by direction and of landuse conditions.

The comparative merits of the various types of interchanges are as shown in Tables 4-8 and 4-9.

4-6-2 Technical Comparison

(1) Location of provision of interchange

The location of interchanges connecting the inter-city toll roads will be the 3 locations as shown below for both the road and free road.

As for connection with the ordinary roads, analysis is made for the 10 locations as shown in Table 4-12 from the point of traffic demand, future transportation network, town planning, future landuse, etc., and installation at 6 locations is proposed for both the cases of toll road and free road. Moreover, in the case of a free road, the structure will be of partial access control so that vehicles can also enter the Ring Road from the frontage roads between interchanges.

Note: ----- Designed Interchanges

(2) Determination of the type of interchange

Studies on the type of interchange to be adopted for the intersection with the 9 radial roads are made according to the items listed in Section 4-6-1 for the three cases of the Ring Road: (1) adopting the uniform toll rate system, (2) adopting the sectional fare rate system, and (3) being a free road. The process is as shown in Fig. 4-17 and the selected types of interchanges are summarized in Fig. 4-18 ~ Fig. 4-20.

The various factors analysed, the traffic volume and the construction cost of the interchanges are summarized from Table 4-16 to Table 4-24.

Since there is little difference in forecasting traffic volume due to the design speed (120 km/h or 100 km/h) the traffic volume for the design speed of 120 km/h is adopted both for the cases of uniform toll rate and sectional fare rate alternatives. For the free road the results of the 100 km/h design speed are adopted.

The landuse plan prepared by Jakarta City is used for evaluation of the landuse of the vicinity of interchanges.

4-6-3 Study on the Intervals of Interchanges

The locations of interchanges of this Ring Road are shown in Fig. 4-27.

There is one section not to be able to keep the necessary interval for allocation of the traffic signs, which is from I.C.-8 (STA. 25+565) to I.C.-9 (STA. 24+570). In the following study for this section is described.

(1) Interval of Interchanges

Fig. 4-25 Tollway (Uniform Rate and Distance Proportional Toll Rate)

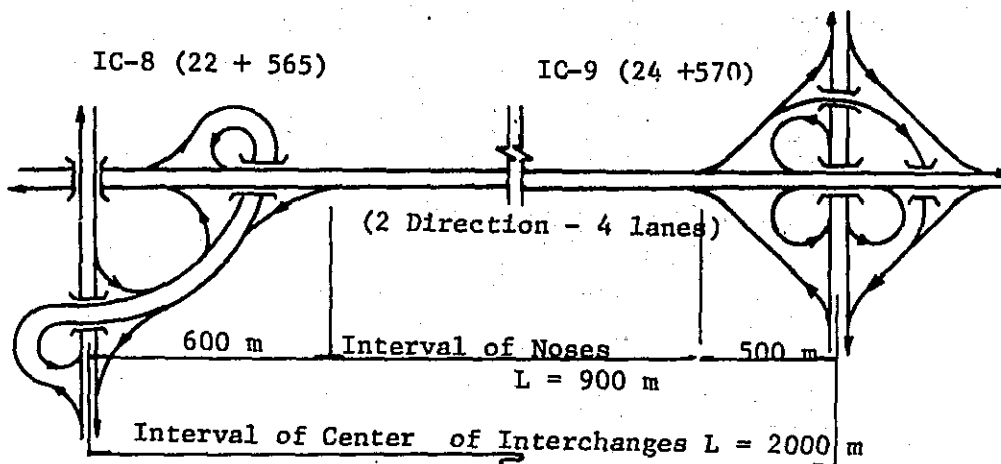

Fig. 4-26 Toll Free

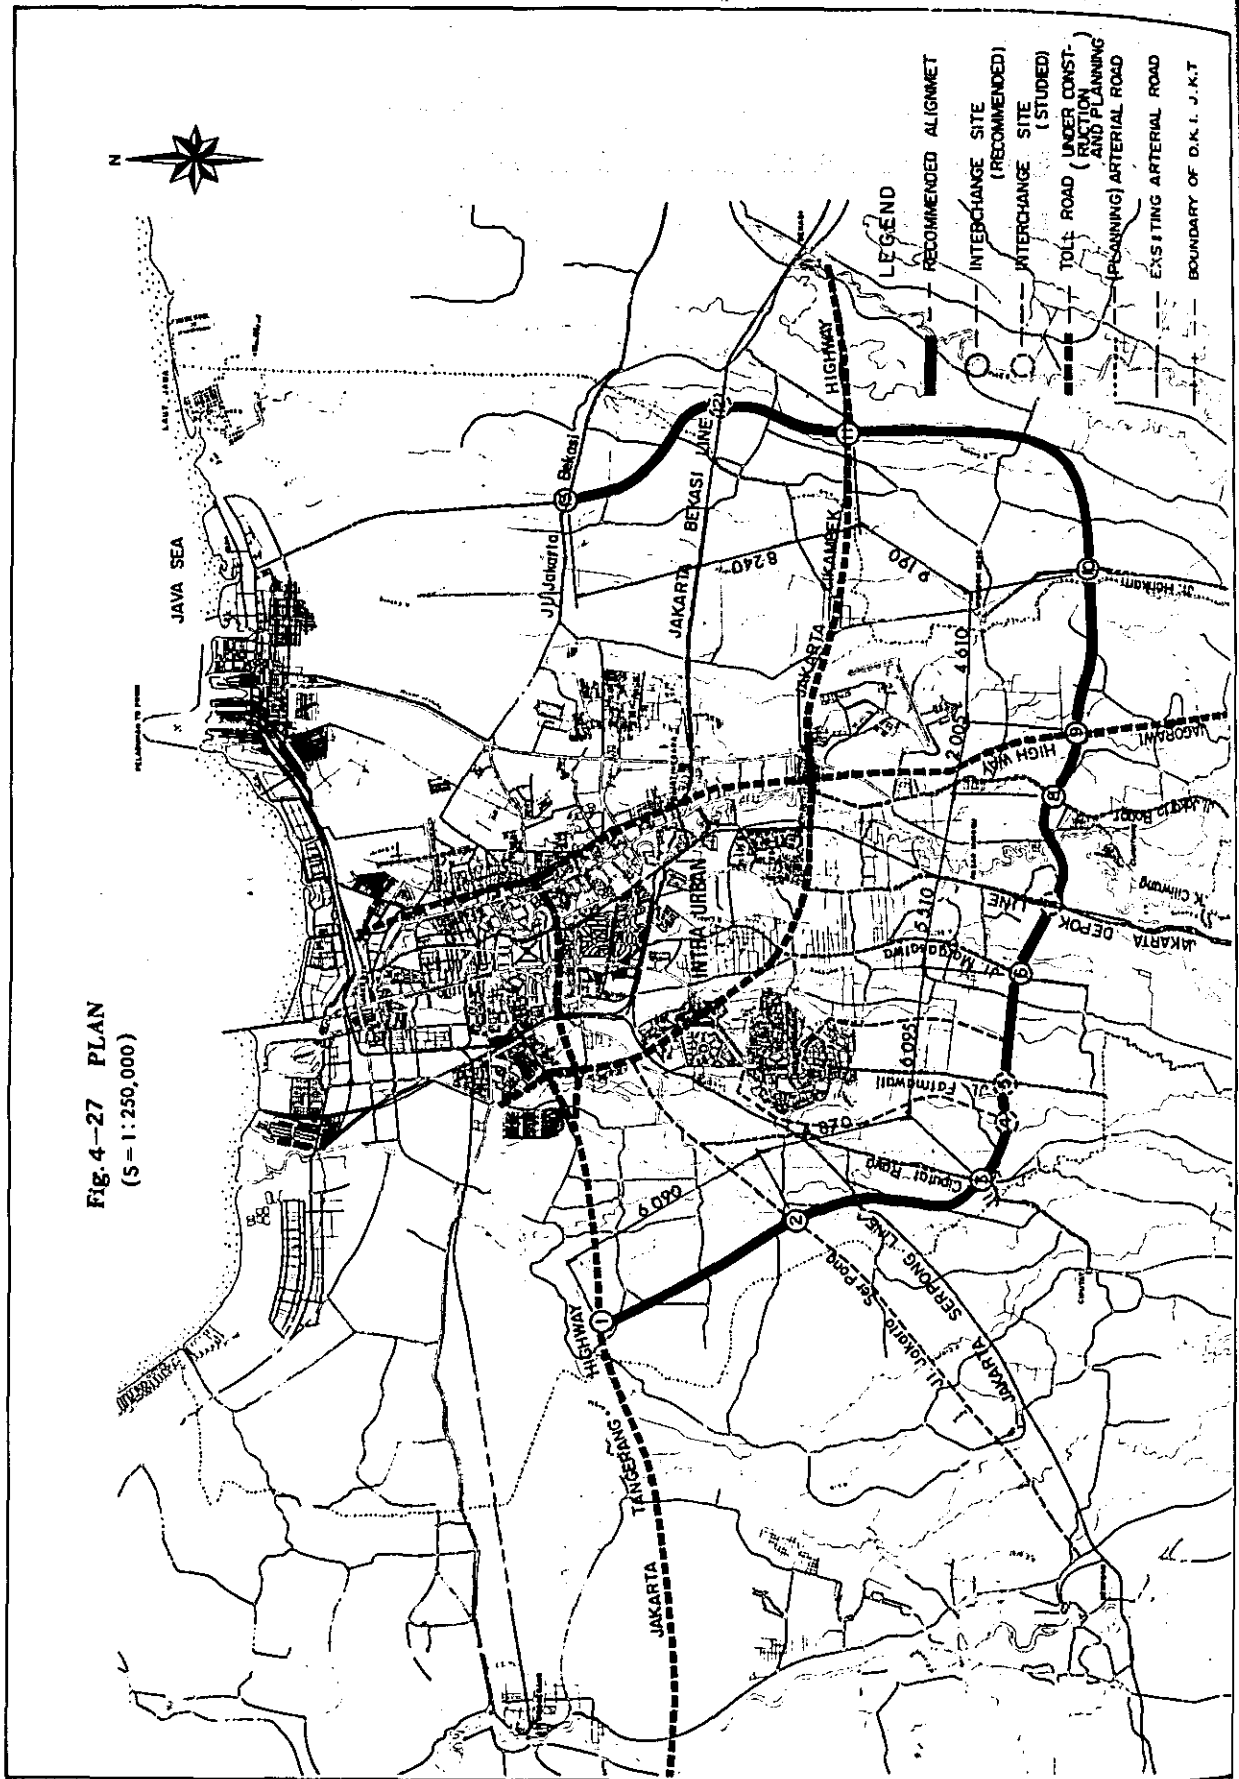

Fig. 4-27 PLAN
(S = 1:250,000)

Fig. 4-28 INTERVAL OF THE INTERCHANGE BETWEEN IC-8 AND IC-9

(S = 1 : 10,000)

(2) Studies for weaving traffic

The weaving traffic volume at Interchanges by alternative is shown in the following figures.

Fig. 4-29 Uniform Toll Rate (T-01; Toll-Flat-120 km/N-A11-13.5 Rp/km)

Fig. 4-30 Distance Proportional Toll Rate

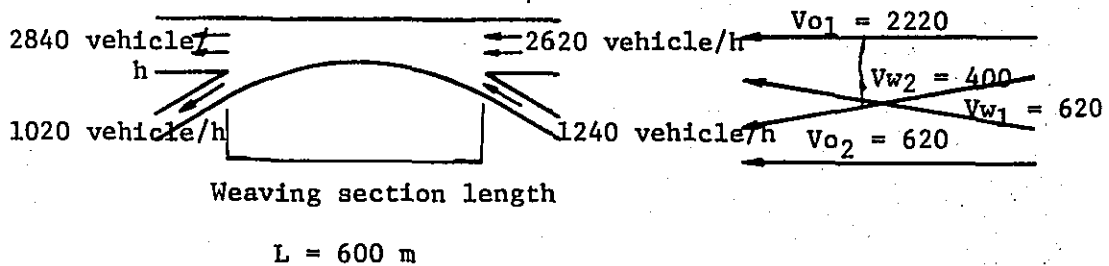

Fig. 4-31 Toll Free (F-01; Free-100 km/h-A11)

As shown above, in case of uniform toll rate, the weaving traffic is so small to be no problem.

But, in the cases of distance proportional toll rate and toll free, some examination for lanes of the weaving section should be needed.

In case of distance proportional toll rate:

$$N = \frac{1110 + 2 \times 220 + 930 + 930}{1820} = 1.9 < 2 \text{ lanes}$$

In case of toll free:

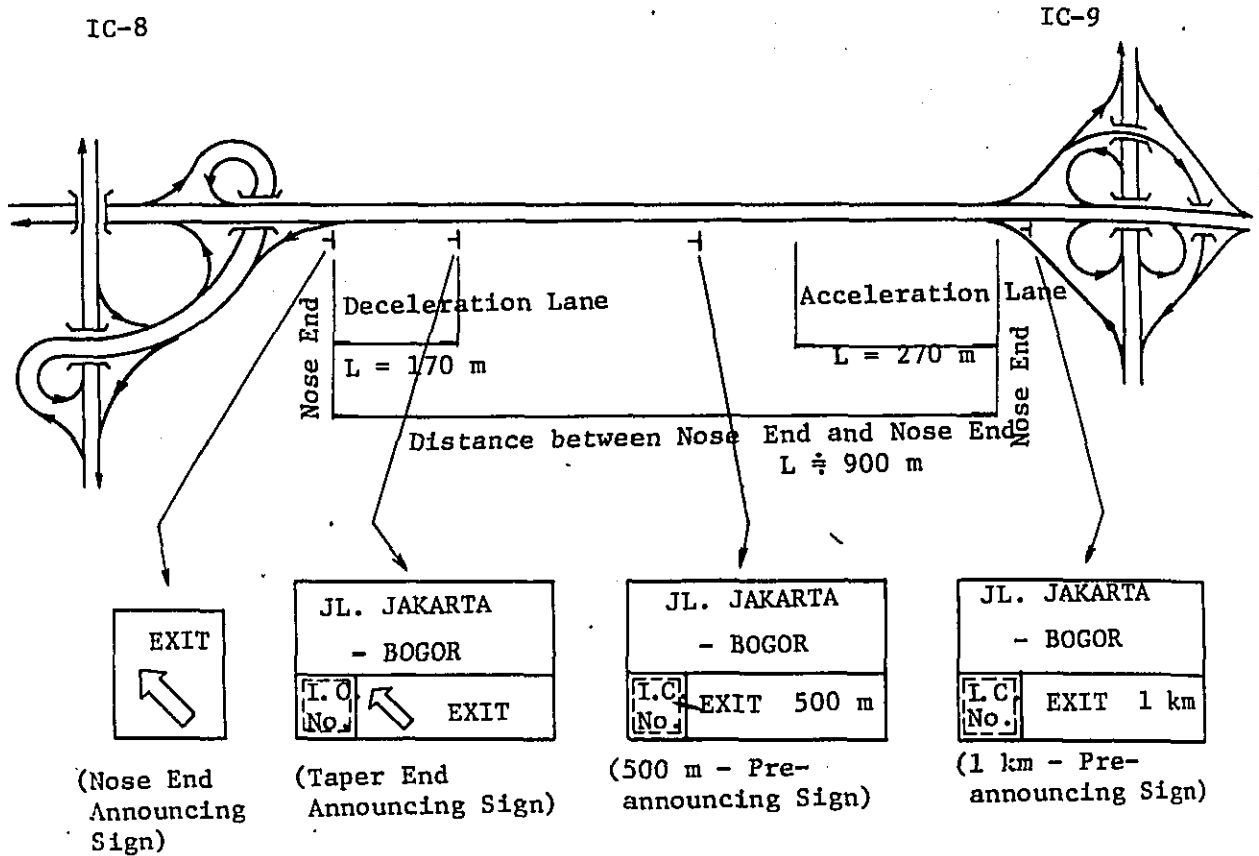

$$N = \frac{620 + 1.6 \times 400 + 2220 + 620}{1780} = 2.3 < 3 \text{ lanes}$$

From above calculation, for both cases, additional lanes in the weaving section are not needed.

(3) Allocation of traffic signs

The allocation of traffic signs is shown in Fig. 4-32. In this figure, although 2 km-preannouncing sign is avoided, 1 km-preannouncing sign and 500 m-preannouncing sign are allocated as overhead signs of enlarged size to keep the traffic safety.

Fig. 4-32 Arrangement of the Traffic Sign (IC-8 ~ IC-9)

4-7 Summary of Comparative Alternatives

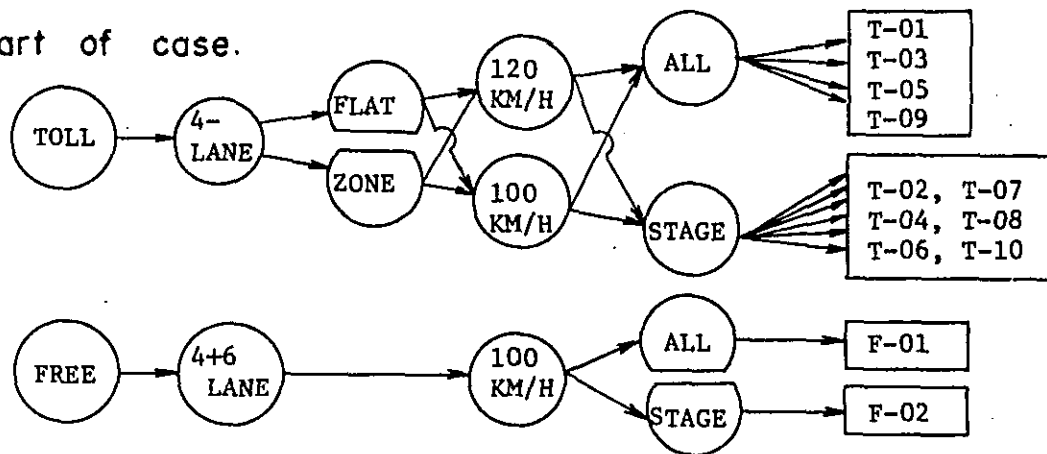

In the previous section a description of the various factors for the planning of the main route and its interchanges as shown in Fig. 4-2 has been made and the 12 alternatives established for comparative analysis in the feasibility study of this project are summarized in Fig. 4-25.

CHAPTER 5 FORECAST OF FUTURE TRAFFIC VOLUME

5-1 Method of Forecast and Alternatives

5-1-1 Basic Concept on Demand Forecast

From the point of view of the Jakarta Ring Road being a part of the urban transport facility for Jakarta, the following are the problems of the existing traffic situation which the Ring Road will have to contribute to solving.

(1) Securing of traffic capacity

The Ring Road has to serve as a distributor and collector road for the commuting traffic that concentrates into the urban center during the peak hours and also serve to provide a circular traffic facility to the traffic generated through the development of the low density areas of the city.

(2) Securing of proximity

The Ring Road has to provide a means of free access to all parts of the city of Jakarta.

(3) Provision of good service

The Ring Road has to fulfil the requirements of a speedy, safe, comfortable and convenient transport facility.

To answer to the above requirements, the basic concept is analysed in the following paragraphs.

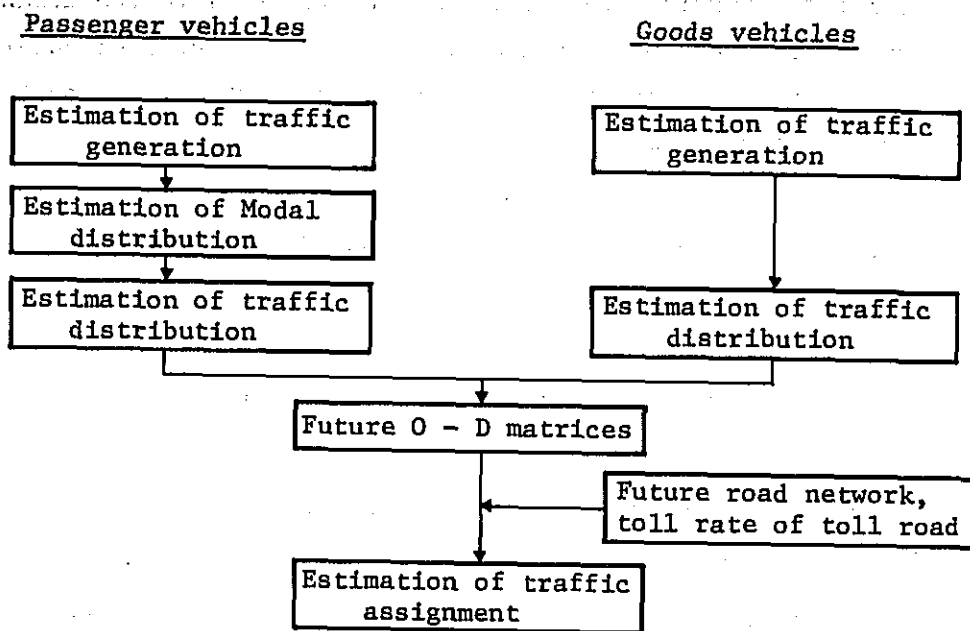

In estimating the traffic demand of Jakarta, the passenger vehicle traffic is based on the analysis of the daily activities of the populations, and the traffic demand is quantified in the concept of 'trips.' Also, as may be seen from the results of the traffic surveys and travel speed surveys, the problems of present traffic in Jakarta are mainly concentrated in the morning peak commuting hours. Therefore, besides the analysis of the daily traffic phenomenon of passenger vehicles, the supply and demand relation during the peak hours is also analysed.

Forecast of goods vehicle traffic is based on the goods vehicle trips generated through future goods flow, and careful studies are made of the future changes of goods handling facilities such as ports, cargo terminals, etc. The characteristics of goods vehicle

traffic are that the variation of traffic is stable in relation to time variation in the day, as has been verified through past surveys, and analysis on goods vehicles traffic is therefore made only for daily traffic.

The basic concept for forecast of traffic demand may be summarized in the flow chart as shown in Fig. 5-1.

Fig. 5-1 Conceptual Flow Chart of Forecast of Traffic Demand

5-1-2 Estimation of Passenger Vehicle Traffic

The passenger vehicle traffic volume in forecast basing on the person-trip and the basic process is described below and summarized in the flow chart shown in Fig. 5-2, whereby analyses are made for the daily and the hourly traffic volumes.

(1) Analysis of the O-D matrices of 1972 (person-trip).

The 1972 O-D matrices by B/M and the person-trip O-D matrices by JMATS were analysed for their conditions of generation and relation to economic indicators.

(2) Formulation of traffic generation model and distribution model.

From the basic O-D matrices, the person-trip generation and distribution models were formulated.

(3) Establishment of 1976 O-D matrices (person-trip).

Basing on the economic indicators, and using the generation and distribution models formulated, the O-D matrices were calculated for the year 1976, which is the base year of this study.

(4) Checking of the established O-D matrices at screen line.

Theoretical O-D matrices are distributed to the traffic lines and checked against actual cross-section traffic volumes at screen lines in order to verify the distribution methodology adopted.

(5) Determination of the control total of future person trip.

The control total of future person trip is calculated from the future economic indicators.

(6) Analysis of modal split

The control total of future person trip of passenger vehicles is split into passenger car trips and bus trips.

(7) Estimated of trip generation by zones

Trip generation by zones is estimated for passenger cars and buses.

(8) Determination of future road network

The future road network to be taken into consideration is determined taking into consideration the future urban activities and economic activities of the city.

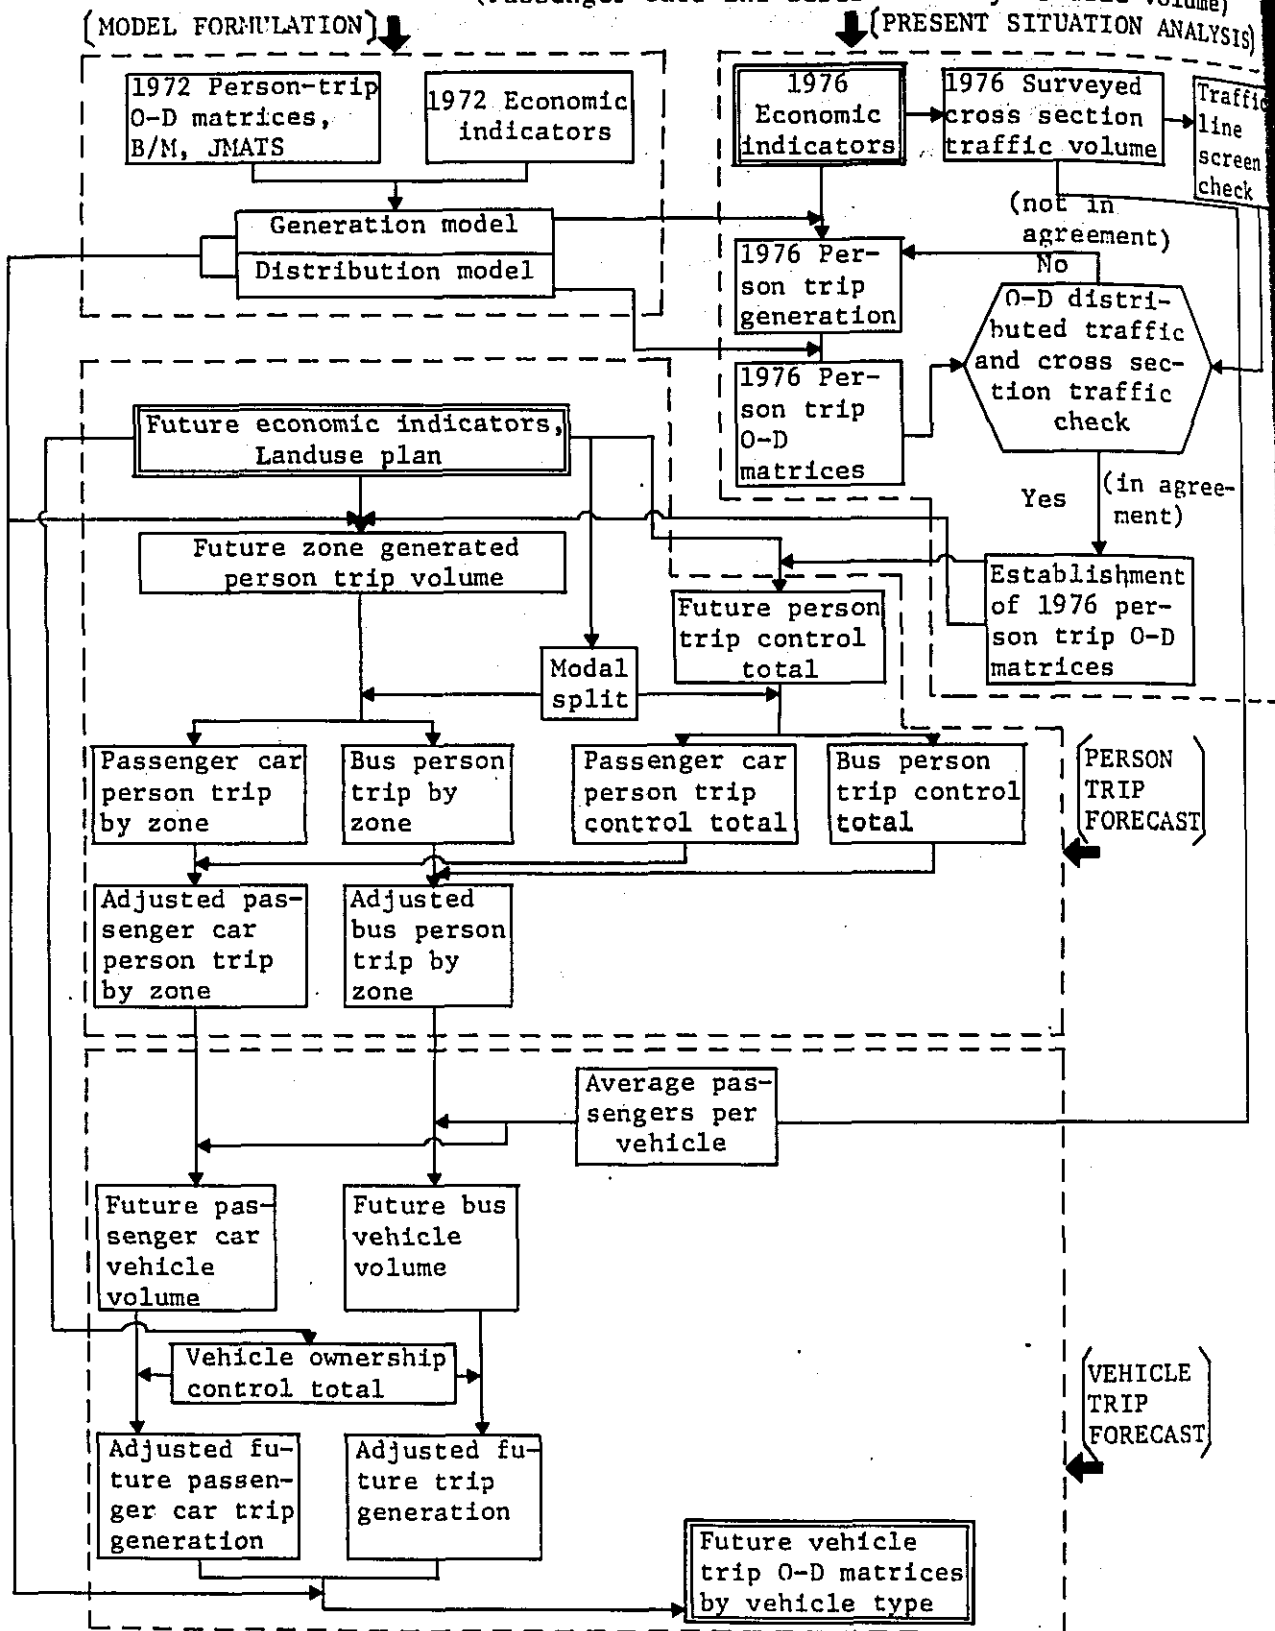

(9) Establishment of future O-D matrices

The O-D matrices are established taking into consideration the future changes in inter-zonal relation after completion of the future road network.

(10) Determination of the toll rate

Toll rates for both the case of uniform toll and that of sectional rate are set within the limit of the benefits estimated for the road users.

Fig. 5-2 Flow Process of Establishment of O-D Matrices for Passenger Vehicle
(Passenger Cars and Buses in daily traffic volume)

(11) Traffic assignment

Traffic assignment is made for the different alternatives together with the goods vehicle traffic in the manner described in subsequent section.

5-1-3 Estimation of Goods Vehicle Traffic

The goods vehicle traffic volume is forecast by analysing the relation of production and consumption of major commodity items in Jakarta and the volume of goods flow between Jakarta and other regions by mode of transport and by traffic direction. The work process of the basic component factors is described below and also summarized in the flow chart in Fig. 5-3.

(1) The consumption volume of main commodity items in the whole of Indonesia in 1973 is computed from the production volume and the imported and exported volume of each item.

(2) The consumption volume of Jakarta is computed as a share of the national total consumption by the proportion of economic indicators, population, etc.

(3) The goods flow in and out of Jakarta (including goods flow by ship) and the goods flow within Jakarta City are estimated from the balance between production in Jakarta, basing on statistical data, and consumption in Jakarta as computed in step (2) above.

(4) From the information on the goods flow by modes of transport (including ship) between Jakarta and other regions, collected through surveys, 1972 B/M O-D matrices, port statistics and statistics of Jakarta City, adjustments are made for the goods flow volume calculated for the 3 major items in production and consumption, in order to establish the volume of goods flow in 1973.

(5) From the figures established in step (4) for the goods flow volume by modes of transport (including ship) for the year 1973 between Jakarta and other regions, the pattern of goods flow for 1976 is established by using the model equation between the goods

flow volume and economic indicators and also taking into consideration the masterplan for the port of Tg. Priok.

(6) The production and consumption of major commodity item in Jakarta were calculated in relation to economic indicators and population, and from the goods flow volume of 1976 established in step (5), the volume of goods flow by truck for the year 1976 by directions is estimated.

(7) The estimated figures obtained in step (6) are checked against the actual survey data on cross section vehicle traffic volume carried out in 1977.

(8) If the check shows favorable results, then the validity of the assumptions in steps (5) and (6) is verified, and the assumptions are adopted for forecast of future goods traffic demand from 1985 to 2000. If the theoretical figures do not tally with actual results, the assumptions in steps (5) and (6) are modified and the process repeated for establishment of theoretical volume for 1976.

(9) The goods flow volume by modes of transport for 1985 to 2000 between Jakarta and other regions is established using the model formulated in step (5) and basing on the masterplan for Tg. Priok.

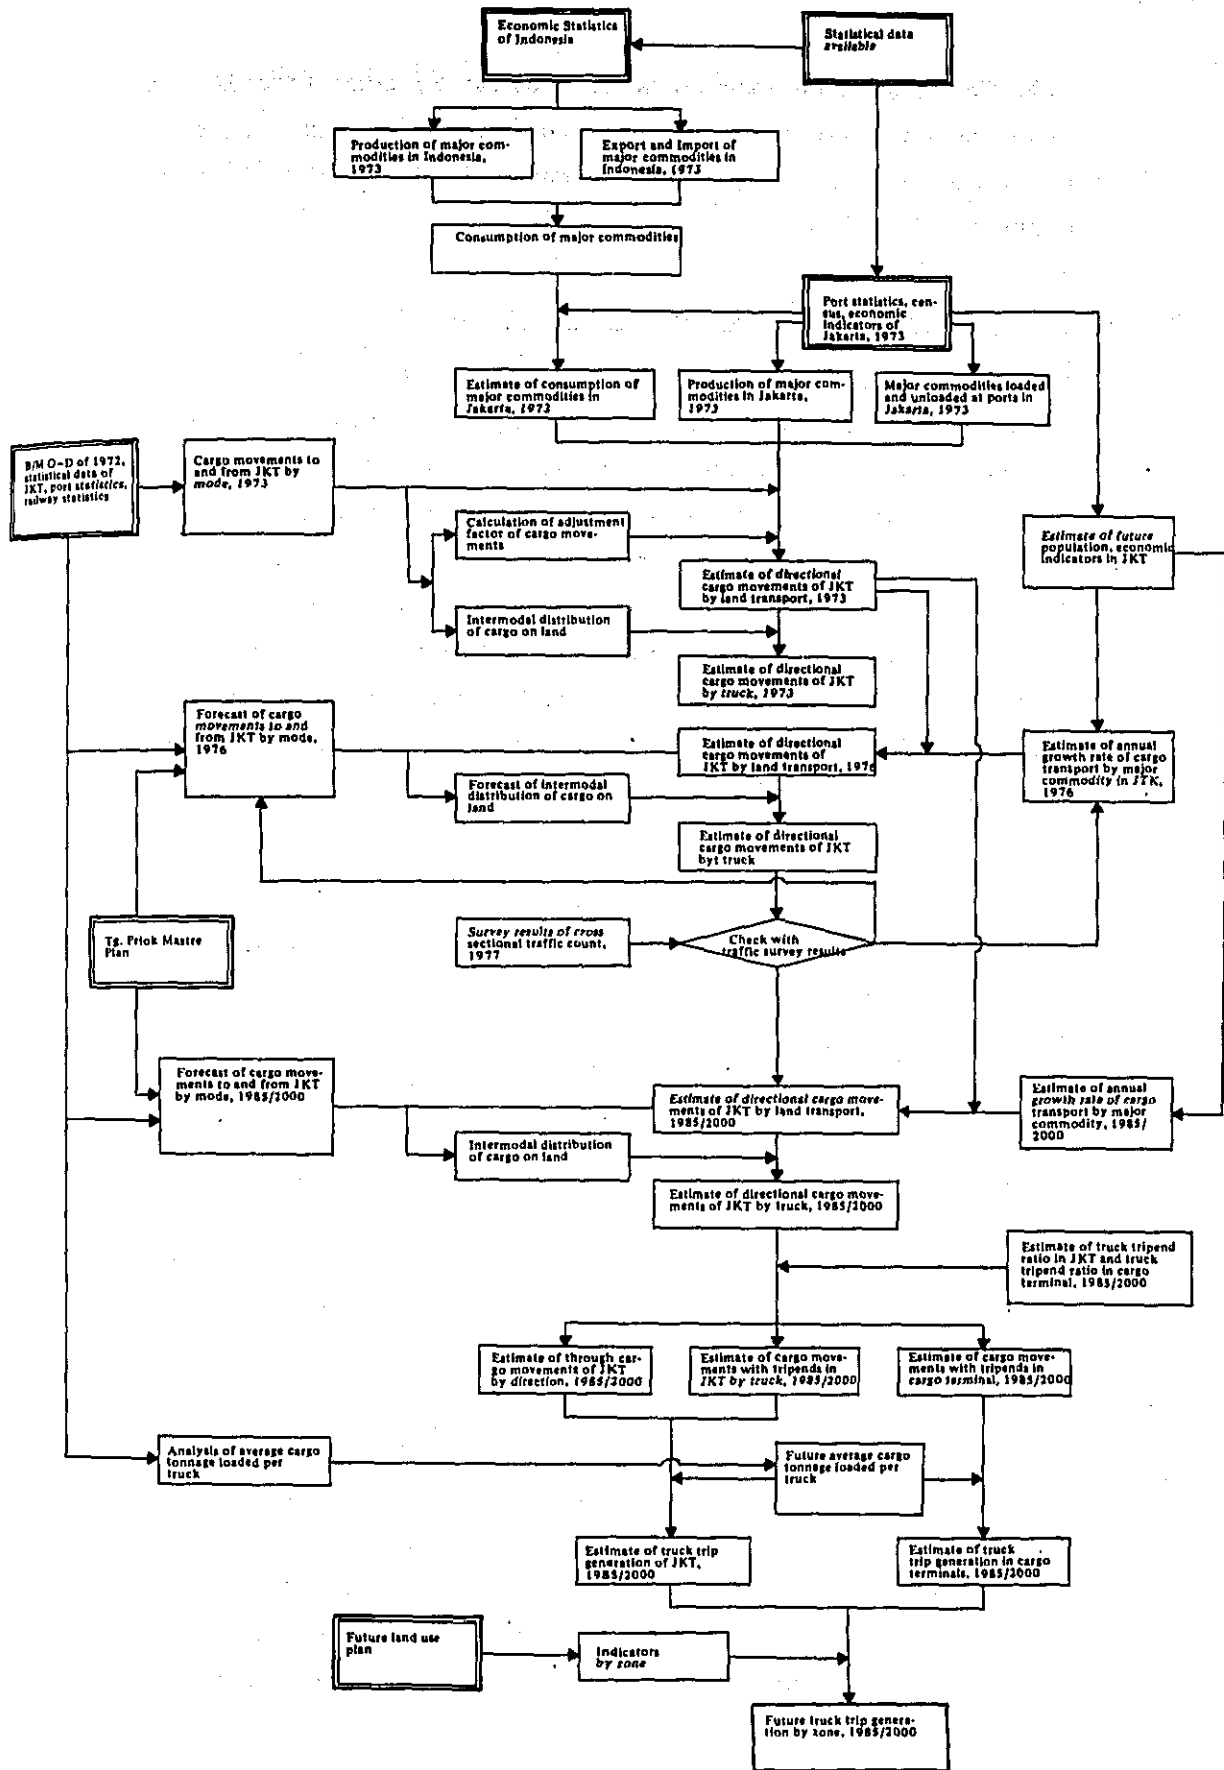

(10) From the production and consumption of major commodity items in Jakarta forecast from future economic indicators and population and the relation with the goods flow volume by modes of transport established in step (9), the volume of goods flow by truck is estimated for the year 1985 to 2000.

(11) Estimates are made of the share of trucks entering the urban center and that using the truck terminal.

(12) The average load volume per truck is estimated from the 1972 B/M O-D matrices and other goods flow statistics of Jakarta, and the future average load volume per truck is forecast.

(13) The volume of truck traffic generation is calculated from the results of steps (10), (11) and (12), taking into consideration the rate of usage of the truck terminal.

Fig. 5-3 Flow Diagram for the Analysis of Truck Trip Generation by Zone

(14) The generated truck traffic volume by zone is calculated from the economic indicators by zone based on the future land-use plan. The above process is summarized as shown in the flow chart in Fig. 5-3.

5-1-4 Comparative Studies of Forecast Alternative

As described previously, the forecast of demand is separately made for persons flow and goods flow, and various alternatives concepts and methods are compared. The basic principle is to make comparative analysis of all possible alternatives. However, since this will incur very enormous volume of data, even if with the assist of the electronic computer, it is necessary to make selective elimination of some alternatives basing on the possibility from the points of present and future urban activities of Jakarta. In the following, a description is made of the comparative analysis of the various items and the reason for their respective observations.

(1) Comparative alternatives on traffic generation

From the past trend of urbanization of Jakarta, it is observed that the future development will be along the same trend of concentrated urbanization centering around the existing CBD. In anticipation of the future economic growth of Jakarta it can be deduced that the urban activities of Jakarta will also increase in intensity. From the standpoint that besides being a commercial and business center, the city of Jakarta is also a potential residential region capable of providing favorable residential services, it can be expected that problems in transportation, housing, environment and other urban aspects will in future become more acute. To ensure future healthy urban activities in Jakarta, the maintenance of harmony between the source of traffic generation and the urban transport facilities is of great importance. This has been clearly indicated by examples of other major cities in the world. On analysis of the balance between the urban activities and the transport facilities in CBD of Jakarta, it is found that the one-point concentrated pattern of

urban development is very undesirable, and in the forecast of traffic generation the calculation is made based on a pattern that a portion of the commercial and business facilities within the CBD has dispersed to the periphery of Jakarta. It is without saying that the Ring Road will play a very important role in maintenance of transport facilities to ensure activities of the dispersed urban functions.

(2) Comparative alternatives on traffic distribution

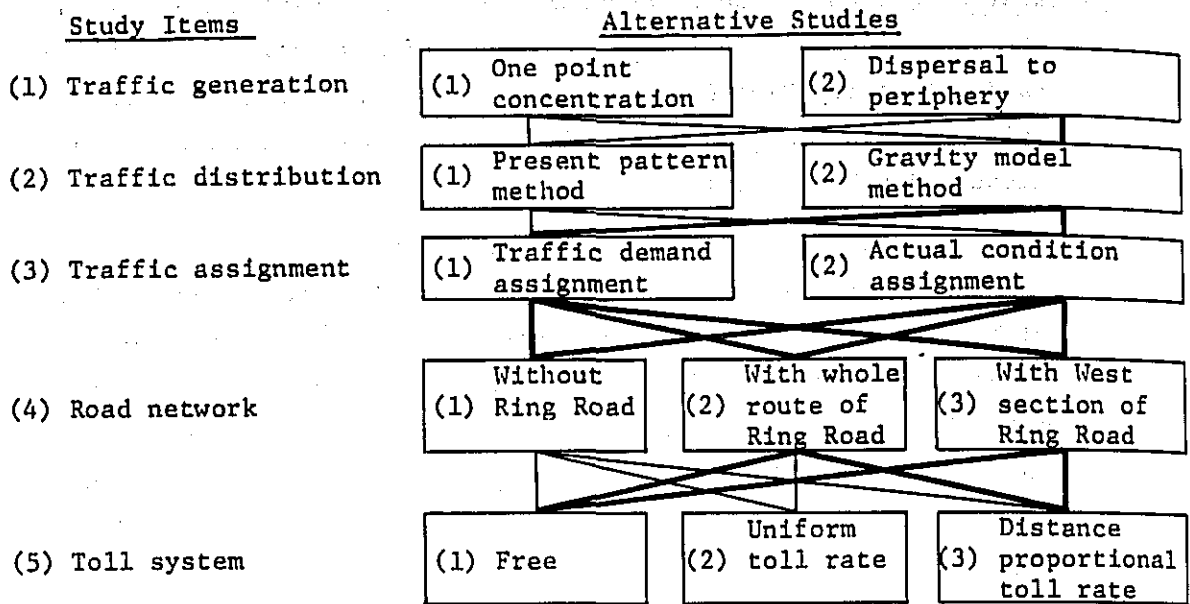

For the consideration on the future relation between the regions within the city and between the city and other regions, the "present pattern method" of distribution and the "gravity model method" which is generated from the present pattern are studied, and the analysis is made based on the gravity model method and also from the point of future distribution of population, the "opportunity model" is also studied. The present pattern method is very effective for the forecast on a short term but is not effective for a long term forecast whereby conspicuous changes in urban phenomena can be expected, such as in the case of the project under study. Therefore, the gravity model method is adopted taking into consideration the future changes of urban activities, the future improvement and construction of urban transport facilities (mainly roads) and the consequent changes in distribution pattern.

(3) Comparative alternative on traffic assignment

The study on the project road is made for both the case of opening the road as (1) a free public road and the case of the road as a toll road. The toll systems under comparative studies are for (2) the case of uniform toll rate and (3) the case of distance - proportional - increase toll rate.

The above mentioned comparative alternatives are summarized in Fig. 5-4.

Fig. 5-4 Comparative Alternatives for Traffic Forecast

Note: ——— denotes flow of alternatives studied.

5-2 Indicators and Car Ownership by Zone

5-2-1 Indicators

Indicators by zone which have been examined for traffic demand forecast are classified as follows:

(1) Indicators of population and economic activities

Population, principle source of traffic generation, is analysed and estimated by categories of the residential population (by density, by residence category) for trip generation and the employed population (by sector, by work places by residential places) for trip destination respecting the future landuse plan.

(2) Indicators for landuse

Respecting the relation between the transportation system plan and the landuse plan, indicators are studied in both cases of the concentrated pattern and the dispersed pattern.

(3) Indicators on traffic demand

Estimation of the traffic demand should be influenced by both categories of indicators of population and economic activities and those of landuse because of its nature. In this study, the demand will methodologically reflect the changes of them.

Also, the car ownership, being the indicator for a passenger car trip generation, is analysed as the function of income conditions.

(4) Indicators on transport facilities

Several alternatives on the road network are studied for the entire studied area and on a zone basis, analysis is made on particularly the sources of goods trip such as the locations of the zones with goods handling facilities, ports, and cargo terminals and also the future scale of the facilities.

Since the above factors have very strong inter-relation in the operation the factors cannot be estimated independently but co-ordination has to be made between the factors. The conceptual relation between the factors is as shown in Fig. 5-5.

Fig. 5-5 Conceptual Relation between the Various Factors

5-2-2 Forecast of Vehicle Ownership

As described in section 1-3-3 on the present situation of vehicle ownership, it is seen that the rate of ownership in Jakarta shows a very high correlation with the per capita GRDP, and forecast of future vehicle ownership is made basing on the regressive equation of the relationship.

(1) Forecast of future GRDP

Except for the year 1974, the real annual average growth rate of GRDP for the period 1970 to 1974 was recorded at 9% ~ 12%. On the otherhand the annual growth rate of national GDP for the same period was 7% ~ 8%.

Considering the accumulation of private sector investment and public investment, and the pivotal role of Jakarta in the economic activities of Indonesia, it can be anticipated that the GRDP of Jakarta will maintain a high growth rate for the future. On the otherhand, the population of Jakarta has been increasing at a high rate of over 4% in pace with the urbanization of Jakarta. Such high rate of population increase has exceeded the capacity of population absorption of Jakarta and is not only detrimental to the healthy economic development of the city but also brings about social problems.

It is in view of this that the Jakarta Masterplan (1965-1985) and the JABOTABEK plan were prepared in order to disperse the population of Jakarta to the periphery. On the side of investment,

efforts were made to promote the industrial development of Bogor, Tangerang and Bekasi so that the whole of JABOTABEK region will, as an integral metropolitan region, be developed under a well-balanced overall regional development plan.

From the above considerations, the future annual rates of growth of GRDP in Jakarta are assumed as follows:

1970 ~ 1980 : 9%
 1981 ~ 1990 : 8%
 1991 ~ 2000 : 7%

Accordingly, the past and future GRDP of Jakarta will be as shown in the following tables.

Table 5-1 GRDP and Its Average Annual Growth Rate in Jakarta

| Item | 1970 | 1971 | 1972 | 1973 | 1974 |
|--|---------|---------|---------|---------|---------|
| GRDP (Million rupiah in 1969 constant price) | 234,893 | 260,483 | 283,761 | 319,744 | 370,616 |
| Per capita GRDP (rupiah) | 54,642 | 57,136 | 59,545 | 64,293 | 71,512 |
| Annual growth rate (%) | 9.3 | 10.9 | 8.9 | 12.7 | 15.9 |

Source: Regional income of Jakarta, 1969 ~ 1974.

Table 5-2 Forecast of Future GRDP in Jakarta

| | 1980 | 1985 | 1990 | 1995 | 2000 |
|--|---------|---------|-----------|-----------|-----------|
| GRDP (Million rupiah in 1969 constant price) | 621,559 | 913,274 | 1,341,899 | 1,882,083 | 2,639,718 |
| Per capita GRDP (rupiah) | 94,462 | 119,695 | 159,370 | 207,506 | 276,990 |

(2) Future rate of car-ownership

The future rate of car ownership is calculated with the regressive equation established in section 1-3-3 and shown below:

$$Y = 0.506 X - 1.915$$

where, X : per capita GRDP (in 1,000 rupiah)

Y : vehicles/1,000 persons

Table 5-3 Future Rate of Vehicle Ownership

| | 1980 | 1985 | 1990 | 1995 | 2000 |
|-------------------------------------|--------|---------|---------|---------|---------|
| Per capita GRDS (rupiah) | 94,462 | 119,695 | 159,370 | 207,506 | 276,990 |
| Per capita GRDP (US\$) | 313 | 397 | 529 | 688 | 919 |
| Vehicles/1,000 persons | 45.9 | 58.7 | 78.7 | 103.1 | 138.2 |
| Total number of vehicles (in 1,000) | 302.0 | 447.9 | 662.7 | 935.1 | 1,317.0 |

Note: US\$1 = Rp 301.5 (at 1969 average conversion rate)

A list of rate of vehicle ownership of other countries in the world in relation to the per capita GDP in 1969 constant price is given below for reference purpose.

Table 5-4 Per Capita GDP and Rate of Vehicle Ownership in Several Countries

| Country | *Per capita GDP (US\$) | Vehicles/1.000 persons |
|----------------------|------------------------|------------------------|
| Japan | 1,944 | 147 |
| United States | 4,578 | 510 |
| France | 2,813 | 297 |
| Fed. Rep. of Germany | 2,526 | 217 |
| Italy | 1,556 | 186 |
| Sweden | 3,697 | 292 |
| U.K. | 1,987 | 237 |
| Thailand | 185 | 8.3 |
| Brazil | 349 | 29.3 |
| Venezuela | 1,013 | 68.7 |

*Note: At 1969 constant price

Spurce: Statistical Yearbook, 1973, United Nations

For purpose of cross-checking, the interrelation between rate of vehicle ownership and per capita GDP of the countries listed are plotted against the graph of the regressive equation adopted for Jakarta as shown in Fig. 5-6.

Fig. 5-7 TREND DIAGRAM OF VEHICLE OWNERSHIP BY TYPE IN JAKARTA

Fig. 5-6 PER CAPITA GDP AND RATE OF VEHICLE OWNERSHIP IN SEVERAL COUNTRIES

From the figure, it may be seen that the future rate of Jakarta City is higher than those of the reference countries in relation to the per capita GDP. However, considering that in the case of Jakarta, the forecast is made for a metropolitan area, the higher figure is considered tolerable, and it is concluded therefore that the regressive equation adopted is ample valid for forecast of future rate of vehicle ownership in Jakarta.

(3) Vehicle ownership by types of vehicles

The statistical data on the vehicle type composition is shown in Table 5-5. It is difficult to determine the future composition, but from the data it is noted that from 1971 to 1975 the composition of bus has remained comparatively stable at around 4.7 - 5% whereas the composition of passenger cars has gradually decreased from 77.5% to 73.7%. On the other hand, the share of trucks has shown an increasing trend from 17.8 to 21.6. This is due to the fact that Jakarta is most highly concentrated in population in Java and in the whole of Indonesia, and, as a commercial and business center, the demand on goods is great and that it has the port of Tg. Priok which caters for international and inter-insular trade, and with the large storage and industry area in the hinter-land of the port is being developed. Moreover, the industrial development in the neighbourhood of Jakarta also contributes to a large demand in transport of goods by truck.

Table 5-5 Composition Ratio by Type of Vehicle

| | 1971 | 1972 | 1973 | 1974 | 1975 |
|------------------------------|-------|-------|-------|-------|-------|
| Total vehicles (in 1,000) | 122.8 | 134.9 | 152.6 | 177.4 | 207.0 |
| Passenger car(%) | 77.5 | 76.5 | 75.7 | 73.8 | 73.7 |
| Truck (%) | 17.8 | 18.5 | 19.3 | 21.3 | 21.6 |
| Bus (%) | 4.7 | 5.0 | 5.0 | 4.9 | 4.7 |
| Total (%) | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |

The future composition by type of vehicle is determined by time trend regression as shown in Fig. 5-7 and the various parameters on the regressive equation are as follows:

| | |
|---|---------------------------------|
| Passenger car: | Where X : Year (71, 72) |
| $Y_p = 14.25 X - 920.75$ (R = 0.985) | Y_p : Number of passenger car |
| Truck: | Y_T : Number of truck |
| $Y_T = 5.85 X - 395.31$ (R = 0.984) | Y_B : Number of bus |
| Bus: | R : Correlation coefficient |
| $Y_B = 0.99 X - 64.57$ (0.998) | |

The composition is determined by conversion of the number of vehicles derived from the above equation and the results are summarized in the following Table.

Table 5-6 Forecast Future Vehicle Type Composition

| Vehicle type | 1976 | 1980 | 1985 | 1990 | 1995 | 2000 |
|---------------|--------------|--------------|--------------|--------------|--------------|--------------|
| Passenger car | 73.0 | 71.5 | 70.5 | 69.9 | 69.5 | 69.3 |
| Truck | 22.2 | 23.7 | 24.7 | 25.4 | 25.8 | 26.0 |
| Bus | 4.8 | 4.8 | 4.8 | 4.7 | 4.7 | 4.7 |
| Total | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |

From the forecast results of future total number of vehicles and the future vehicle type composition, the future number of vehicles by types are determined as follows:

Table 5-7 Forecast Future Vehicle Ownership by Vehicle Type in Jakarta

| Vehicle Type | % | 1976 | | 1985 | | 1990 | | 1995 | | 2000 |
|---------------|------------|----------------|------------|----------------|------------|----------------|------------|----------------|------------|----------------|
| | | 1,000 Vehicles | % | 1,000 Vehicles | % | 1,000 Vehicles | % | 1,000 Vehicles | % | 1,000 Vehicles |
| Passenger car | 73.0 | 154.8 | 70.0 | 313.5 | 69.0 | 457.3 | 69.0 | 645.2 | 68.5 | 902.1 |
| Truck | 22.0 | 46.7 | 25.0 | 112.0 | 26.0 | 172.3 | 26.0 | 243.1 | 26.5 | 349.0 |
| Bus | 5.0 | 10.5 | 5.0 | 22.4 | 5.0 | 33.1 | 5.0 | 46.8 | 5.0 | 65.9 |
| Total | 100 | 212.0 | 100 | 447.9 | 100 | 662.7 | 100 | 935.1 | 100 | 1,317.0 |

(4) Forecast of vehicle ownership by zone

The traffic demand, particularly of the person trip, which is estimated in the form of the number of trips made by each person in a day, varies according to the living environment represented by the vehicle ownership situation of the household, and in this study analysis is made along this line. The rate of vehicle ownership is closely connected to the economic activities and especially when the objective region is in zone or household or smaller units, the rate is related to the average income level of the small unit. In Jakarta, since the income level may be represented by the housing situation, and the housing situation of the area is related to the population density, in order to estimate the vehicle ownership by zone, the calculation is made from the rate of vehicle ownership based on the analysis of the population of each zone and the income structural composition of the population. From the results of such analysis, the rate of vehicle ownership according to the density of population by target years is shown in the following table.

Table 5-8 Rate of Vehicle Ownership by Population Density by Year

| Rank . | Population Density (persons/ha) | Rate of Ownership (vehicles/1,000 persons) | |
|--------|------------------------------------|---|------|
| | | 1985 | 2000 |
| a | ~ 250 | 122 | 222 |
| b | 250 ~ 400 | 42 | 78 |
| c | 400 ~ | 14 | 25 |
| K | ~ 500 | 9 | 17 |

The vehicle ownership for each zone calculated by multiplying the figures is shown in the above table with the population of each zone according to the population density classification, and with the previously established total vehicles for Jakarta as the control total, the number of vehicles calculated is modified accordingly. The results of the number of vehicles by zone is as shown in Table 5-9.

Table 5-9

FUTURE PASSENGER VEHICLES REGISTERED BY ZONE

| Zone No. | 1985 Estimated | 1985 Definite | Zone No. | 2000 Estimated | 2000 Definite |
|----------|----------------|---------------|----------|----------------|---------------|
| 1 | 2,589 | 2,677 | 1 | 2,435 | 2,613 |
| 2 | 3,416 | 3,532 | 2 | 3,233 | 3,470 |
| 3 | 8,397 | 8,682 | 3 | 14,461 | 15,523 |
| 4 | 6,734 | 6,963 | 4 | 9,766 | 10,483 |

5-3 Development Plans and Future Transport Network

Guidelines of the future development plans in DKI Jakarta are as follows by Replita II.

- | | |
|--|---|
| 1. Development in the Commercial and Service Sectors | Economical Infrastructure Development |
| 2. Development in the Industrial Housing and Tourism Sectors | Social, Administrative Facilities Improvement |

Under these guidelines, as principal policies, execution of the migration planning and promotion of constructions in various fields, are being studied, in order to encounter the intensive population growth in DKI Jakarta.

Among them, some of deeply related plannings with traffic demands are as follows:

- Improvement plan of intra city traffic
- Improvement plans of land transports and sea transports facilities
- Extension of central markets of foods
- Preparation of warehouses
- Development of Kampung houses

For those plans and executions, major urban transport facilities such as roads, ports, airports terminals and others have been developed and extended.

In this study, those situations are fully respected for a demand forecast, described as follows:

(1) Smooth the urban transport

Present situation on the urban transport will be highly declined onto the road transport. In recent years, it has progressed in a bid extent in the betterment and new construction of roads, and this condition is reflected on the future road network of this study.

(2) Improvement of land transports and marine transports facilities.

The importance of the marine transport facilities, Tg. Priok Port and Sunda Kelapa Port will be kept growing and for this reason the cargo flow through Tg. Priok Port is one of the important element for the demand forecast. The masterplan of Tg. Priok Port is fully respected.

(3) Preparation and development of storehouses and terminals.

In order to smooth the future cargo movements, it must be needed to establish the proper cargo circulation system to get resultantly a decrease of the truck running trip-kilometers. And this also has some influence to promote the urban transport to smoothing and develop the transport facilities in general.

Three cargo terminals are proposed in this study to achieve the above mentioned purpose in the suburban area of DKI Jakarta connecting the ports, the terminals and the demand sites to smooth the flow of cargo.

(4) Others

Among other development plans, the construction of a new international airport and new residential areas in suburban areas give the great impact on the promotion of demand and change of pattern.

5-4 Establishment of 1976 O-D Matrices

5-4-1 Methodology

The basic data of present situation used in traffic forecast are on the person trip basis using the 1972 B/M O-D matrices and the JMATS O-D matrices. As for goods flow, the available data other than the above O-D matrices are the 1973 data on production and consumption.

The base year for the analysis in this study is determined in 1976, and all economic factors from the available year to 1976 are analysed of the variation and checked against the cross section traffic volume of 1976. The trips under study are divided into passenger vehicles trips and goods vehicles trips.

5-4-2 Analyses of Passenger Vehicles

The analysis of passenger vehicles is made based on the 1972 O-D matrices, the 1972 economic indicators and 1976 economic indicators.

(1) Analysis of 1972 O-D matrices

The past O-D matrices available on person-trip are the 1972 B/M O-D and the JMATS O-D matrices. The zone division of these O-D matrices are as follows:

Table 5-10 Zone Division of Past O-D Matrices

| O-D Matrices | Jakarta | Periphery | Remarks |
|--------------|----------|-----------|--------------------|
| B/M O-D | 1 zone | 28 zones | |
| JMATS O-D | 29 zones | 3 zones | Medium size zones. |

From the table, it is seen that the B/M O-D are suitable for analysis of long distance trips over a wide region and the JMATS O-D are oriented to analysis of short distance trips within Jakarta. Here, the analysis of traffic in Jakarta will be based on the JMATS zoning and studies of inter-regional trips will be based on B/M O-D matrices.

(2) Formulation of person-trip generation and distribution model.

The model expressing the relation between the economic indicators

and the traffic volume are formulated based on the 1972 generated and distributed traffic volumes.

1) Formulation of trip generation model

From the economic indicators analysed in sections 2-6 and 5-2, the factors which have strong relation with the traffic generation are compiled as follows:

*Analysed variables

The 1972 trip generation volumes by zones (persons/day)

*Analysing variables

1. Resident population (1972)
2. Resident population by income stratum (1972)
3. Resident-based employed population by occupation (1972)
4. Landuse area by usage classification (1972)
5. Vehicle ownership
6. Number of factories by size
7. Land area by population density (1973)
8. Employed-location-based employed population by sector (1972)

The other additional factors analysed are as follows:

9. Zone area
10. Area of kampung districts
11. Future landuse area

Basically the model is a multi-variable linear model, and analysis is made for the various situation of correlation between the generated volume and the variable factors.

The results are as follows:

- a. With resident population by stratum as variables (case 1)

$$Y = 3,193.9X_1 + 144.8X_2 - 473.0X_3 \quad (R=0.903)$$

where, X_1 = resident population in permanent housing units.

X_2 = resident population in semi-permanent housing units.

X_3 = resident population in temporary housing units.

- b. With resident population by stratum as variable (case 2)

$$Y = 3,428.2X_1 - 697.2X_2 \quad (R= 0.887)$$

where, X_1 = resident population in permanent housing units.

X_2 = resident population in semi-permanent housing units.

- c. With resident population and employed location based on tertiary industry employed population as variables.

$$Y = 1,151.4X_1 - 138.9X_2 + 2,235.0Z_1 \quad (R= 0.960)$$

where, X_1 = resident population in permanent housing units

X_2 = resident population in semi-permanent housing unit.

Z_1 = tertiary industry employed population.

- d. With landuse area as variables

$$Y = 111.5X_1 + 1,138.8 - 238.7X_3 - 70.4X_4 \quad (R= 0.977)$$

where, X_1 = area of residential area

X_2 = area of commercial and public facilities areas

X_3 = area of industrial area

X_4 = area of other usage

- e. With employed population by sector as variables

$$Y = -8.1X_1 - 1.0X_2 + 3.8X_3 \quad (R= 0.953)$$

where, X_1 = primary industry employed population

X_2 = secondary industry employed population

X_3 = tertiary industry employed population

Basing on the resulting inter-relation matrices between the analysing variables and the analysed variables, and also fully taking into consideration the availability of data in 1976 and the possibility of forecast for the variables in the target years, it is decided that the variable that can best explain the trip generation is that of (c) where the resident population and the tertiary industry employed population are adopted as variables. The basic concept is that the zone trip generation is defined by the residential population and the day time employed population.

2) Formulation of distribution model

Considering that the target year of forecast will extend to as far as 20 years in future, and that during this analysis period, there are many possible changes in the road conditions and situations including the implementation of the Ring Road, the "gravity model" and the opportunity model were chosen for comparative studies, eventually leading to the adoption of the following gravity model. From the analysis of the present O-D matrices on such factors as the inter-zonal travel time, the trip generation volume of each zone, and the inter-zonal trip distribution, the parameters of the model are determined as follows and also graphically shown in Fig. 5-8.

Gravity Model

$$T_{ij} = T_i \times T_j \times \frac{k}{D_{ij}^n}$$

where, T_{ij} = distributed trip volume between zone i and zone j.

T_i = generated trip volume of zone i

T_j = generated trip volume of zone j

n and k = coefficients

D_{ij} = required travel time between zone i and zone j

Parameters for passenger vehicles

| <u>Type of vehicle</u> | <u>n</u> | <u>k</u> | <u>Correlation coefficient</u> |
|------------------------|----------|------------------------|--------------------------------|
| Passenger vehicle | 1.00 | 1.047×10^{-6} | R = 0.80 |

(3) Cross checking at the screen line

To verify if the 1976 person trip O-D matrices so theoretical established do correctly reflect the movement of the population in Jakarta for the year 1976, five screen lines as shown in Fig. 5-9 are prepared for cross checking. In the checking process, in order to make comparison against the results of traffic surveys carried out in April, 1977, the assigned traffic volumes based on the theoretical 1976 O-D matrices are adjusted to 1977 values, and the results are as shown in Table 5-11. Since the theoretical

FIG. 5-1
RELATION BETWEEN DISTANCE
AND DISTRIBUTION PATTERN
(PERSON (M))

results can reasonably reflect the actual traffic situation, the theoretical O-D is confirmed as the established 1976 O-D matrices, based on which future forecast process is carried out.

Table 5-11 Comparison of Traffic at the Screen Lines

| <u>Screen</u> | Traffic volume based on theoretical O-D | | | Actual | Survey | <u>Cross section</u> |
|---------------|---|---------------------------------|-----------------------------|-----------------------------------|----------------------------|----------------------|
| | 1976 dis-tributed person-trip | 1976 con-verted vehicle traffic | Adjusted 1977 Sedan traffic | 1977 volume cross section traffic | 1977 cross section traffic | |
| | persons/day | vehicles/day | vehicles/day | vehicles/12 hr. | vehicles/day | |
| A | 50,215 | 8,425 | 9,183 | 10,133 | 13,173 | Jakarta East |
| B | 149,429 | 25,072 | 29,836 | 33,608 | 43,690 | Jakarta South |
| C | 50,686 | 8,504 | 12,416 | 13,366 | 17,376 | Jakarta West |
| D | 77,799 | 13,054 | 15,926 | 15,237 | 19,808 | Jakarta intra-urban |
| E | 206,976 | 34,728 | 41,326 | 51,909 | 67,482 | Jakarta intra-urban |

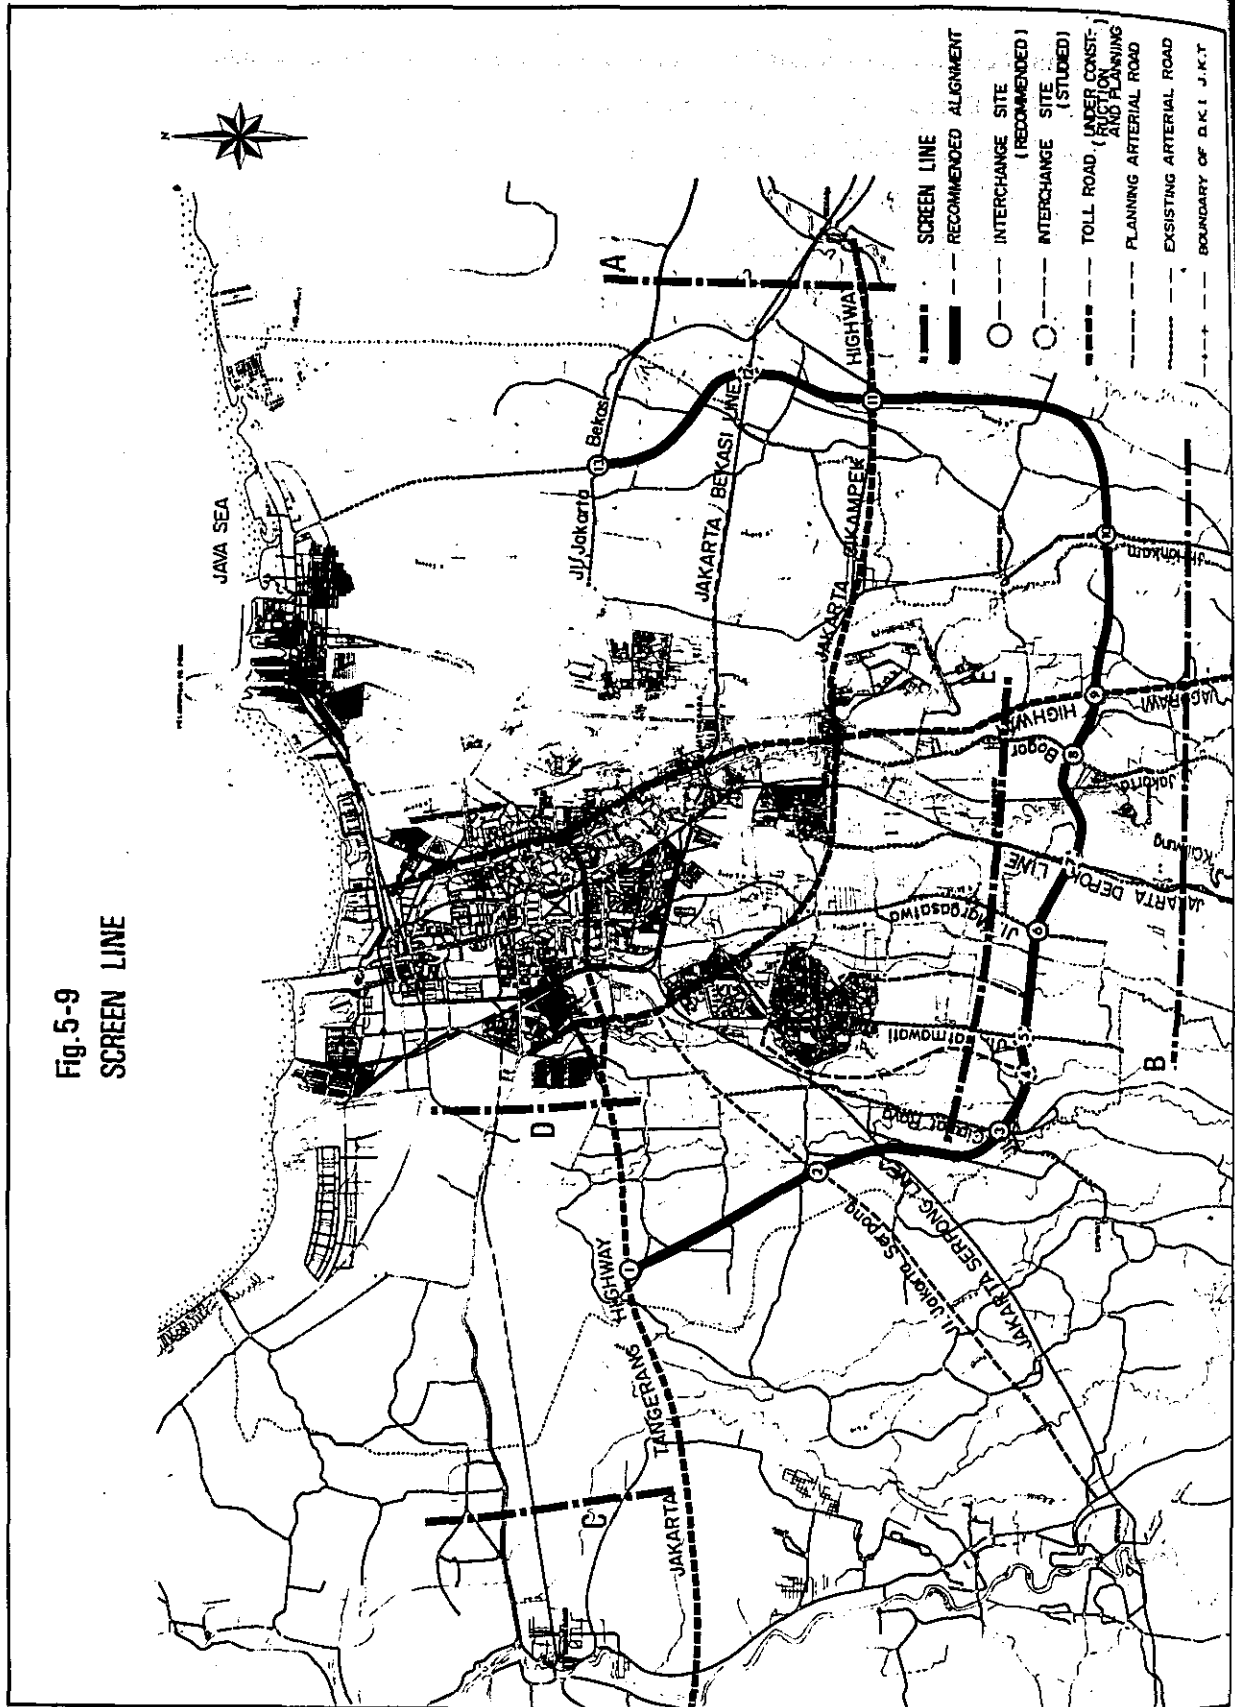

The coordination of the person-trip volume and vehicle traffic volume and of the 1976 and 1977 vehicle traffic volumes are carried out as follows.

The person trip volume is converted into vehicle traffic volume by the vehicle type composition obtained from traffic survey and the average number of persons per vehicle is computed at 5.96 persons/vehicle. The adjustment of 1976 volume to 1977 volume is based on the past B/M data from 1971 to 1975 of the growth of traffic for each direction, and the average growth was 1.21 times. The surveyed 12 hours traffic volume is converted to 24 hour volume by the day time coefficient of 1.30 from the results of B/M and DKI 24 hour traffic surveys.

5-4-3 Analysis of Goods Flow

(1) Adjustment of production and consumption in Jakarta
As described in section 1-4, the production and consumption of

Fig. 5-9
SCREEN LINE

commodities calculated for Jakarta has been adjusted in consideration of the regional disparity of production and consumption between Jakarta and the rural area so that for the agricultural and fishery products, the consumption for Jakarta is increased by 20% whereas the production and consumption volumes for Jakarta are increased by 30%.

(2) Total goods inflow and outflow

The basic concept of goods flow is that the difference between production and consumption of a commodity will become the quantity of goods flow for the commodity between the region and other regions, and the lesser between production and consumption will induce an intra-regional goods flow.

However, in economic activities, the difference between production and consumption needs not necessarily form into goods flow within the region in total and a portion will flow out of the region in the form of leakage. Taking this point into consideration an assumption is made that an additional 20% is taken for the difference between production and consumption to make up part of inter-regional goods flow, so that the total of the inflow and outflow will be double the 20%, or 40%.

(3) Goods inflow and outflow at the ports

Of the total goods flow into and out of Jakarta, the volume handled at the ports are assumed by main commodity items as follows.

- °Rice: 50% of the volume handled (in and out) at Tg. Priok flows between Tg. Priok and Jakarta city.
- °Timber: 50% of consumption of Jakarta flows in from Tg. Priok.
- °Textile, apparels and household wares: 10% of consumption in Jakarta and 20% of the flow between Jakarta and other regions are handled in Tg. Priok.
- °Steel products and fuel: The entire consumption volume flows in from Tg. Priok.
- Other commodity items: 15% of the total production and consumption volumes flow through Tg. Priok.

Table 5-12 Production and Consumption of Goods in Jakarta, 1973

| Goods | Production | Consumption | Difference | Cargo movement of JKT | | |
|------------------------------------|------------|-------------|------------|-----------------------|-------------------|---------------------------------------|
| | | | | to/from outside JKT | to/from Tg. Priok | to/from outside JKT by land transport |
| Farm Food Corps | 213,839 | 1,954,784 | 1,759,845 | 1,841,599 | 495,756 | 1,345,843 |
| Rice | 30,726 | 897,347 | 866,621 | 878,911 | 309,673 | 569,238 |
| Maize | 143 | 149,464 | 149,321 | 149,378 | 22,441 | 126,937 |
| Cassava | 8,486 | 473,239 | 464,753 | 468,147 | 72,259 | 395,888 |
| Sweet Potato | 836 | 101,676 | 100,840 | 101,174 | 15,377 | 85,797 |
| Peanuts | 282 | 11,447 | 11,165 | 11,278 | 1,759 | 9,519 |
| Soybeans | 0 | 21,515 | 21,515 | 21,515 | 3,227 | 18,288 |
| Fruits | 60,678 | 191,681 | 131,003 | 155,274 | 37,854 | 117,420 |
| Vegetables | 110,438 | 100,988 | 9,450 | 49,845 | 31,714 | 18,131 |
| Potatoes | 2,250 | 7,427 | 5,177 | 6,077 | 1,452 | 4,625 |
| Estate Crops | 0 | 304,463 | 304,463 | 304,463 | 45,669 | 258,794 |
| Animal Husbandry | 52,805 | 109,555 | 58,768 | 79,486 | 24,355 | 55,131 |
| Livestock slaughtered | 5,966 | 50,236 | 44,270 | 46,656 | 8,430 | 38,226 |
| Eggs | 3,299 | 13,558 | 10,259 | 11,579 | 2,529 | 9,050 |
| Fresh milk | 4,080 | 3,071 | 1,009 | 2,237 | 1,073 | 1,164 |
| Meat | 39,460 | 42,690 | 3,230 | 19,014 | 12,323 | 6,691 |
| Fishery Products | 9,751 | 55,130 | 45,379 | 49,279 | 9,732 | 39,547 |
| Forest Products | 0 | 622,997 | 622,997 | 622,997 | 311,499 | 311,498 |
| Industrial Products | 1,566,369 | 5,235,689 | 3,957,782 | 4,526,638 | 2,373,886 | 2,152,752 |
| Food beverages & tobacco | 468,136 | 763,435 | 355,299 | 518,553 | 175,736 | 342,817 |
| Textile, clothing, furniture, etc. | 213,307 | 120,147 | 93,160 | 141,219 | 40,259 | 100,960 |
| Raw materials & auxiliary | 159,749 | 362,622 | 202,873 | 266,773 | 78,356 | 188,417 |
| Cement | 0 | 307,977 | 307,977 | 307,977 | 46,197 | 261,780 |
| Other construction materials | 278,560 | 492,246 | 213,686 | 325,110 | 115,621 | 209,489 |
| Iron & steel products | 37,272 | 78,579 | 41,307 | 56,216 | 28,882 | 27,334 |
| Fertilizer & pesticides | 57,903 | 6,832 | 51,071 | 53,804 | 9,710 | 44,094 |
| Fuel | 0 | 1,590,390 | 1,590,390 | 1,590,390 | 1,590,390 | 0 |
| Small & household manufacturing | 302,740 | 1,053,049 | 750,309 | 871,405 | 203,368 | 668,037 |
| Other manufacturing products | 108,702 | 460,412 | 351,710 | 395,191 | 85,367 | 309,824 |
| Total | 1,842,764 | 8,282,618 | 6,749,234 | 7,424,462 | 3,260,897 | 4,163,565 |

Deducting the volume of flow through Tg. Priok from the adjusted total volume of goods flow between Jakarta and other regions calculated from the production and consumption of the main commodity items, the difference makes up the volume of goods flow by land. The results are summarized in Table 5-12.

(4) Analysis of goods flow between Jakarta and other regions by modes of transport.

The volume of goods flow between Jakarta and other regions by major commodity items for Jakarta has been listed in Table 5-12. However, this volume which is calculated through indirect calculation has to be verified with direct method.

For this purpose, the total volume of goods flow by modes of transport between Jakarta and other regions as summarized in previous section 1-4-4 and shown in Table 5-13 is utilized and the 1973 volume of goods flow by modes of transport is as shown below.

Table 5-13 Goods Flow by Mode of Transport, 1973

(Unit: 1,000 tons/year)

| <u>By sea</u> | <u>By rail</u> | <u>By truck</u> |
|---------------|----------------|-----------------|
| 8,360 | 1,034 | 8,511 |

The petroleum products which are conveyed into Tg. Priok and flow out directly after processing are not included in the above summary of goods flow volume by sea. The inflow and outflow volume by truck for 1973 is obtained by using the 1972 B/M O-D matrices for truck traffic and adjusting it to 1973 volume by the growth factor from 1972 to 1973 of total volume of truck conveyed goods, and then deducing the through traffic from the total.

(5) Calculation of adjusting factor for total inflow and outflow of goods.

The volumes obtained in step (4) are used as the control total for adjusting the total goods flow volume estimated by accumulation of each major commodity item from the relation of production and consumption and the adjusting factor α is calculated as follows:

$$A = E - F$$

$$(C + D) - (B - F\alpha) = A\alpha$$

$$\alpha = \frac{C + D - B}{A - F}$$

where, A = Total goods flow volume by truck between Jakarta and other regions based on relation between production and consumption.

B = Statistical volume of goods flow by sea.

C = Statistical volume of goods flow by rail.

D = Statistical volume of goods flow by truck.

E = Total goods flow volume estimated from the difference of total production and consumption.

F = The portion in E which is the goods flow volume between Tg. Priok and Jakarta.

Therefore, the calculation is as follows:

$$\alpha = \frac{1,034 + 8,511 - 8,360}{4,164 - 3,261} = 1.312$$

The adjusting factor 1.312 is therefore adopted for adjusting the estimated volume of goods flow in all directions.

(6) Goods flow by direction in 1973

The volume of goods flow by direction is estimated considering the conditions described in steps (1) to (5), and basing on the total volume of goods flow of Jakarta as summarized in Table 5-12.

1) Intra-regional goods flow (excluding flow with Tg. Priok)

From the production and consumption volume by major commodity items as listed in Table 5-12, the estimation is made from the accumulated total of the lesser of the two volumes as follows.

$$1,688,074 \times 1.312 \times 0.8 \times 2 = 3,544 \text{ thousand tons/year}$$

2) Goods flow between Tg. Priok and Jakarta city
(assuming that the volume handled by rail is negligible)

$$3,261,000 \times 1.312 = 4,278 \text{ thousand tons/year}$$

3) Goods flow between Tg. Priok and other regions
(Please refer to Table 5-13)

$$8,360,000 - 4,278,000 = 4,082 \text{ thousand tons/year}$$

Of this volume, the modal split between rail and truck is determined in proportion to the total goods flow by modes between Jakarta and other regions in 1973, as follows.

$$\text{Truck: } 4,082 \times \frac{8,511}{8,511 + 1,034} = 3,643 \text{ thousand tons/year}$$

$$\text{Rail: } 4,082 \times \frac{1,034}{8,511 + 1,034} = 439 \text{ thousand tons/year}$$

4) Goods flow between Jakarta and other regions

$$(8,511 + 1,034) - 4,082 = 5,463 \text{ thousand tons/year}$$

The modal split is made in the same way as step 3) as follows:

$$\text{Truck: } 5,463 \times \frac{8,511}{9,545} = 4,868 \text{ thousand tons/year}$$

$$\text{Rail: } 5,463 \times \frac{1,034}{9,545} = 591 \text{ thousand tons/year}$$

(7) Estimation of 1976 goods flow by direction

1) Goods flow between Jakarta and other regions by mode of transport.

From the past statistical data, it is noted that the volume of goods flow between Jakarta and other regions is well correlated with the per capita GRDP of the population of Jakarta and the time trend method is adopted to estimate the goods flow volume for 1976. However, the volume of goods flow by sea is adopted from the master plan of Tg. Priok and 10% of the volume handled by other ports is added to that of Tg. Priok and then deducting 4% as the portion that is transferred within the port area.

The 1976 total goods flow by modes of transport is thus calculated as follows:

Table 5-14 Goods Flow by Mode of Transport, 1976

| (unit: 1,000 tons/year) | | |
|-------------------------|----------------|-----------------|
| <u>By sea</u> | <u>By rail</u> | <u>By truck</u> |
| 11.19C | 1,218 | 16,385 |

2) Goods flow estimated from production and consumption of major commodity items (reference Table 5-12)

a) Intra-regional goods flow

a-1) The intra-regional flow of food farm crops, livestock and dairy products is determined from the production in Jakarta and that for fertilizer by consumption in Jakarta. Past data show that production of the above products is at a decreasing trend so that, assuming an index of 100 for 1973, the consumption of fertilizer drops to an index of 98. Therefore, the volume of intra-regional flow of food farm crops, livestock, dairy and fertilizer products is calculated as follows:

$$\begin{aligned} \text{In 1973: } & (213,839 + 5,966 + 3,299 + 4,080 + 6,832) \\ & \times 1.312 \times 0.8 \times 2 = 491,246 \text{ tons/year.} \end{aligned}$$

$$\text{In 1976: } 491,246 \times 0.98 = 410,861 \text{ tons/year.}$$

a-2) The intra-regional flow of fresh fish and meat is determined by production in Jakarta and that of textile, apparels and household wares etc., is determined by consumption in Jakarta.

The increase of intra-regional goods flow from 1973 to 1976 is assumed to be proportional to the increase in population.

$$\begin{aligned} \text{In 1973: } & (39,460 + 120,147 + 9,751) \times 1.312 \times 0.8 \\ & \times 2 = 355,517 \text{ tons/year.} \end{aligned}$$

$$\text{In 1976: } 355,517 \times 1.135 = 403,512 \text{ tons/year.}$$

a-3) The intra-regional goods flow of other products is determined by production in Jakarta and the growth from 1973 to 1976 is assumed to be proportional to the growth in GRDP.

$$\begin{aligned} \text{In 1973: } & (408,136 + 159,749 + 278,560 + 37,272 + \\ & 108,702 + 302,740) \times 1.312 \times 0.8 \times 2 \\ & = 2,718,798 \text{ tons/year.} \end{aligned}$$

$$\text{In 1976: } 2,718,798 \text{ tons} \times 1.377 = 3,743,785 \text{ tons/year.}$$

b) Goods flow between Tg. Priok and Jakarta city
(reference Table 5-14)

Assuming that the goods flow by rail is negligible, the goods flow volume through Tg. Priok is split into the volume between the port and Jakarta and that between the port and other regions proportional to the volumes handled in 1973.

In 1973: Between Tg. Priok and Jakarta: 4,278,000 tons/
year

Between Tg. Priok and other regions:

4,082,000 tons/
year

$$\begin{aligned} \text{In 1976: } 11,190,000 &\times \frac{4,278,000}{4,278,000 + 4,082,000} \\ &= 5,706,900 \text{ tons/year} \end{aligned}$$

c) Goods flow between Tg. Priok and other regions
(Unadjusted)

This is obtained by deduction of the volume between Tg. Priok and Jakarta from the total volume handled in Tg. Priok. The volume handled by rail will be subsequently adjusted.

$$\text{In 1976: } 11,190,000 - 5,706,900 = 5,483,100 \text{ tons/year}$$

d) "Through" goods flow volume by truck

The through flow volume by truck for 1973 is estimated by computing the through traffic volume from the 1972 B/M O-D matrices and then multiplying the volume by the growth factor obtained through surveyed cordon increase in traffic from 1972 to 1973.

The 1976 through volume is assumed to increase from 1973 in proportion to the growth in GRDP from 1973 to 1976.

$$\text{In 1973: } 70,000 \times \frac{3,705}{2,677} = 97,000 \text{ tons/year}$$

$$\text{In 1976: } 97,000 \times 1.377 = 133,569 \text{ tons/year}$$

- e) Goods flow between Jakarta and other regions (unadjusted)

The 1976 volume is obtained by deducting from the total of rail and truck flow volumes as shown in Table 5-13, the volume between Tg. Priok and other regions calculated in Step c), and also twofold the through volume calculated in Step d).

$$\text{In 1976: } (16,385,000 + 1,218,000) - (5,483,100 + 133,569 \times 2) = 12,387,038 \text{ tons/year}$$

- f) Adjusted goods flow between Tg. Priok and other regions

The rail transport portion of the flow between Tg. Priok and other regions is calculated from the unadjusted volume obtained in Step c) and Step e) in proportion to the unadjusted total from Jakarta to other regions by adjusting the figures against the frame total of goods transported by rail in 1976, and the truck portion is obtained by deduction of the rail portion from the total flow with others regions.

That is, the goods flow by truck in 1976 is:

$$5,483,100 - 1.218 \times \frac{5,483,100}{5,483,100 + 12,387,038} = 5,482,726 \text{ tons/year}$$

- g) Adjusted goods flow between Jakarta and other regions

The volume is obtained from the unadjusted estimate by deduction of the rail portion according to the method described in Step f).

$$\text{In 1976: } 12,387,038 - 1.218 \times \frac{12,387,308}{5,483,100 + 12,387,038} = 12,386,194 \text{ tons/year}$$

The truck goods flow by direction for 1973 and 1976 may therefore be summarized as follows:

Table 5-15. Goods Flow by Truck by Direction,
1973 & 1976

(unit in 1,000 tons/year)

| | 1973 | 1976 | Growth rate (%) |
|-------------------------------------|-------|--------|-----------------|
| Jakarta - other regions | 4,868 | 12,386 | 2.54 |
| Tg. Priok - other regions | 3,643 | 5,483 | 1.51 |
| Subtotal | 8,511 | 17,869 | 2.10 |
| Through volume | 97 | 134 | 1.34 |
| Total goods flow with other regions | 8,705 | 18,137 | 2.08 |
| Intra-regional | 3,544 | 4,558 | 1.29 |
| Tg. Priok - Jakarta | 4,278 | 5,707 | 1.33 |
| Total flow within region | 7,822 | 10,265 | 1.31 |

(8) Cross checking of goods flow by truck in 1976

The goods flow volume estimated for 1976 is checked by comparing the volume of goods flow across the boundary of Jakarta City against the cross section vehicle traffic volume.

Of the goods flow volume estimated for 1976, the portion that crossed the boundary of Jakarta is 18,137 thousand tons/year as seen in Table 5-15. Assuming 250 working days per year for trucks, the daily volume of goods that crossed the city boundary is 72,500 tons/day. On the other hand, the cross section traffic volume of trucks was recorded at 17,000 vehicles/12hr, according to the results of traffic surveys. (reference section 1-5). Assuming a day time ratio of 1.5 for trucks, the volume of truck traffic in 24 hours is estimated at 25,000 vehicles/day.

Since the traffic survey was carried out in April, 1977, the traffic volume is expected to have increased from 1976. However, disregarding such increase, and assuming that an additional 20% of truck traffic crossed the city boundary from minor roads that were not surveyed, the volume of goods that crossed the city boundary as calculated from traffic volume is as follows:

$$25,000 \text{ vehicles/day} \times 2.5 \text{ tons/vehicles} \times 1.2 = 75,000 \text{ tons/day}$$

The cross checking verifies the validity of the estimated volume of goods flow in 1976, and the estimated figures are adopted in subsequent analyses.

(9) Formulation of goods distribution model

Goods vehicle distribution model is formulated for goods flow within the city by analysis of the present goods vehicle O-D matrices. The model used is the gravity model, just as in the case of person trip distribution. From the present O-D matrices, the relation between inter-zone time distance, the generated volume of each zone and the inter-zonal distribution volume are as shown in Fig. 5-10. And the parameters are calculated as follows:

Gravity Model

$$T_{ij} = t_i \times T_j \times \frac{k}{d_{ij}^n}$$

where, T_{ij} = distributed traffic volume between zone i and zone j.

T_i = generated traffic volume of zone i

T_j = generated traffic volume of zone j

n and k = coefficients

D_{ij} = time distance between zone i and zone j

Parameters

| Vehicle type | n | k | Correlation coefficient |
|--------------|------|------------------------|-------------------------|
| Truck | 1.09 | 8.128×10^{-5} | R = 0.80 |

$\frac{T_1 \times T_2}{T_{12}}$

5-5 Estimation of Future Passenger Vehicle Traffic Generation

5-5-1 Method of Estimation of Traffic Generation

The estimation of traffic generation is carried out by the following two steps.

(1) The establishment of the control total

This involves the estimation of the total intra-regional person trips and the total person trips between Jakarta and other regions, and since the person trip is composed of all types of passenger vehicles excluding trips by rail, the total is subdivided into control totals for passenger cars and that for bus the public transport vehicles.

(2) Estimation of trip generation by modes of transport (passenger car, bus) for each individual zone.

From the rate of vehicle ownership in accordance to income stratum, the passenger car trips and bus trips are estimated for each zone and the total of all zones adjusted with the control to the total established in step (1).

5-5-2 Determination of Future Control Total of Person Trips

In the calculation of the control total, the following alternative methods are studied.

- a. The method based on the average number of trips per person.
- b. The method based on a generation model.
- c. The method based on the rate of vehicle ownership according to population density ranking.

(1) Average number of trips per person

From the analyses of the 1972 O-D matrices and the 1972 resident population the average number of trips per resident population is found to be 0.770 trip end/person.

(2) Generation model

The generation model for estimation of zone trip generation is as follows:

$$Y = 1151.4X_1 - 138.9X_2 + 2.235Z_1$$

where, X_1 = resident population in permanent housing unit.

X_2 = resident population in semi-permanent housing unit.

X_3 = employed population in tertiary industry.

- (3) Rate of vehicle ownership according to population density ranking.

For each rank of population density, the control total of passenger vehicle person trip is obtained as follows:

(Population x rate of vehicle ownership x rate of vehicle usage x average number of persons per vehicle x average number of trips per vehicle).

By calculation of, the vehicle traffic volume x average number of persons per vehicle ÷ average trip length, for passenger car and bus respectively from the present O-D matrices, the total passenger vehicle control total is subdivided into passenger car trip control total and bus trip control total in the proportion so obtained.

The control total calculated by the above three methods are summarized as follows:

| | <u>1985</u> | <u>2000</u> |
|-------------------------------|-------------|-------------|
| 1. Av. No. of trip per person | 5,904 | 8,093 |
| 2. Generation Model | 8,746 | 13,990 |
| 3. Rate of vehicle ownership | 5,298 | 14,514 |

(unit: 1,000 trip ends)

For the following reasons, the results based on the rate of vehicle ownership according to population density ranking is adapted as the control total for this study.

- 1) The method based on the average number of trips per person is not suitable for Jakarta where the urban structure changes at a rapid pace. Also, since the population differs in occupation, age, sex, income, household structure and vehicle ownership, it is unsuitable to apply any single average number of trips uniformly to all population.
- 2) The generation model was formulated with data on a zone basis and the model is therefore basically applicable to a small

region at a zone level, so that although the application of the model to the entire Jakarta may provide a guiding figure, the result is not suitable for use as a control total.

- 3) The method which is based on the rate of vehicle ownership according to population density ranking is an effective method for a region such as Jakarta, where the extreme difference in level of living is existing among the resident population. In our field survey, the relation between housing density and the rate of ownership and the trip generation has been studied and analyzed in order to verify the validity of this method.

On analysis of all the results of calculation it is concluded that method based on the rate of vehicle ownership according to population density level can be applied to the pattern of growth of generated trips and the trip generation by the resident population, and the control total is calculated according to this method. The control total for the trip between Jakarta and other regions is computed as a percentage of the control total for the intra-regional trip at a share determined from the 1972 B/M O-D matrices and added to the intra-regional total. The framework for the various years thus calculated are summarized in Table 5-16.

As for trips generation of zones of external regions, due to the difference in characteristics of internal and external zones, and from the point of availability of data, a different methodology has to be employed. This is done by calculating the growth from the generated trip volume in the present O-D matrices by multiplying the present trip generation with the growth factory for resident population. Since the trip volumes of these external zones are not the total trips generated by the zones but the the trips connecting only with Jakarta, the growth is considered related to the growth of trips in Jakarta. The growth factor for trips generated in external zones in therefore divided as follows:

$$G_i = G_D \times G_{oi}$$

where, G_i = growth factor for trip generation of external zone i.

G_D = growth factor for resident population in Jakarta.

G_{oi} = growth factor for resident population in external zone.

The results of the trip generation of internal and external zones are as shown in Table 5-16.

Table 5-16 Framework of Jakarta for the Key Years

| | 1976 | 1985 | 2000 |
|---|-------------|-------------|--------------------|
| Vehicle Ownership (1,000 vehicles) | | | |
| <u>Passenger car</u> | 154.8(1.00) | 313.5(2.03) | 902.1(5.83) |
| <u>Bus</u> | 10.5(1.00) | 22.4(2.13) | 65.9(6.28) |
| <u>Truck</u> | 46.7(1.00) | 112.0(2.40) | 349.0(7.47) |
| <u>Total</u> | 212.0(1.00) | 447.9(2.11) | 1,317.0(6.21) |
| Resident population (in 1,000) | 5,641(1.00) | 7,667(1.36) | 10,510(1.86) |
| Rate of vehicle ownership (veh/1,000 persons) | | | |
| <u>Passenger car</u> | 27.4(1.00) | 40.9(1.49) | 85.8(3.13) |
| <u>Bus</u> | 1.9(1.00) | 2.9(1.83) | 6.3(3.31) |
| <u>Truck</u> | 8.7(1.00) | 14.6(1.68) | 33.2(3.82) |
| <u>Total</u> | 37.6(1.00) | 58.4(1.55) | 125.3(3.33) |
| Person trip generation (1,000 trips/day) | 2,677(1.00) | 5,298(1.98) | 14,514(5.42) |
| Person trip per resident population (trips/day) | 0.47 | 0.69 | 1.38 ^{*1} |
| Passenger vehicle trip generation (1,000veh/day) | - | 1.047 | 3.080 |
| Trip per passenger vehicle | - | 3.34 | 3.41 ^{*2} |

Note: *1: the 1973 surveyed results of cities in Japan of over 500,000 in population is 1.52

*2: the 1973 surveyed results of cities in Japan of over 500,000 in population is 3.80

5-5-3 Estimation of Trip Generation by Zone, by Mode of Transport

The factors that strongly affect the passenger vehicle trip generation of a zone are (1) future resident population of the zones by population density ranking and (2) Rate of vehicle ownership by population density ranking. The indicators by population density ranking for 1985 and 2000 are as shown below and the steps for estimation of trip generation by zone are as shown in the subsequent page.

Table 5-17 Person Trips by the Population Density Category

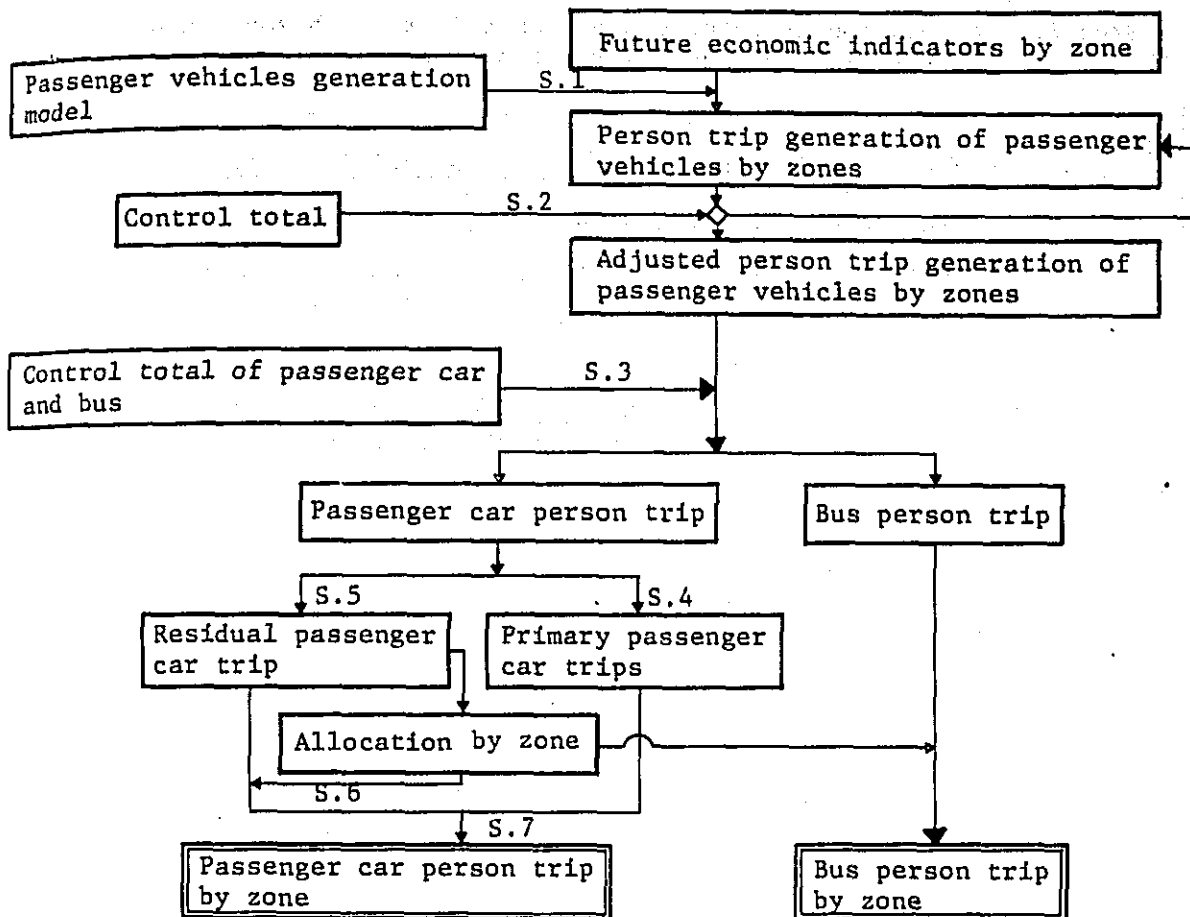

| Rank | Population density (persons/ha) | 1985 | | 2000 | | Average rate of vehicle usage | Av. No. of persons per vehicle | Av. No. of trips per person | 1985 generated person-trip (in 1,000/day) | 2000 generated person-trip (in 1,000/day) |
|--------------------|---------------------------------|-----------------------|--|-----------------------|--|-------------------------------|--------------------------------|-----------------------------|---|---|
| | | Population (in 1,000) | Rate of vehicle ownership (Veh/1,000P) | Population (in 1,000) | Rate of vehicle ownership (Veh/1,000P) | | | | | |
| a | ~250 | 1687.3 | 122 | 2,842.0 | 222 | 0.80 | 2.0 | 2.5 | 823 | 2,524 |
| b | 250~ 400 | 1408.4 | 42 | 2,092.2 | 78 | 0.85 | 2.7 | 2.3 | 312 | 861 |
| c | 400 | 1564.1 | 14 | 2,075.1 | 25 | 0.90 | 3.5 | 2.1 | 145 | 343 |
| d | 500 | 3007.2 | 9 | 3,502.7 | 17 | 0.90 | 3.5 | 2.1 | 179 | 394 |
| Total (or Average) | | 7667.0 | 41 | 10,510.0 | 86 | - | - | - | 1,459 (1.00) | 4,122 (2.83) |

Reference: Figures for Japanese cities of 500,000 ~ 1,000,000 in population, 1973.

- 1) Rate of ownership: 207.2 vehicles/1,000 persons
- 2) Average number of trips per vehicle: 3.8 trips

Based on the conditions described above, the passenger car trip and bus trip are estimated as follows:

Fig. 5-11 Flow of Estimation of Passenger car and Bus Person Trip

- Step 1. The person trip generation by passenger vehicles is computed for each zone with the generation model based on resident population by state and employed population in tertiary industry.
- Step 2. Adjustment with the control total.
- Step 3. Division of total generated person trip into passenger car person trip and bus person trip using the control totals for passenger car and bus.
- Step 4. Calculation of primary passenger car person trip for each zone by: resident population by density rank x rate of vehicle ownership x rate of vehicle usage x av. no. of persons per vehicle x 2.
- Step 5. Deduction of total of primary passenger car person trip from the total passenger cars person trip.
- Step 6. Allocation of residual trip to the zones proportional to the residual passenger car person trip of the zones.

- Step 7. Determination of the zone passenger car person trip by adding primary trip and residual trip for each zone.
- Step 8. Allocation of total bus person trip to each zone in proportion to the residual passenger car person trip of each zone.

5-5-4 Conversion of Person Trip Volume into Vehicle Traffic Volume

With the passenger car and bus person trip for each zone determined, the next step is to convert the person trip volume into vehicle traffic volume by the following formula.

$$\text{Passenger car (or Bus) vehicle trip} = \frac{\text{Passenger car (or Bus) person trip generated}}{\text{Average number of persons per vehicle (or Bus)}}$$

The average number of persons per vehicle is obtained by calculating the weighted average of the number of persons per vehicle by population density ranking used in the calculation of the control total for future passenger vehicles person trip generation. The number of persons per vehicle by population ranking is as listed below, and based on this the average number of persons for passenger cars is calculated at 2.43 persons/vehicle for 1985 and 2.33 persons/vehicle for 2000.

Table 5-18 Average Number of Persons per Passenger Car by Population Density Ranking

| <u>Ranking</u> | <u>Population density(p/ha)</u> | <u>Av. No. of persons per passenger car</u> |
|----------------|---------------------------------|---|
| a | ~ 250 | 2.0 |
| b | 250 ~ 400 | 2.7 |
| c | 400 ~ | 3.5 |
| k | ~ 500 | 3.5 |

The average number of persons per bus is set at 33 persons/bus for both 1985 and 2000, taking into consideration the present statistics and future trend.

Table 5-19-1 FUTURE TRIPENDS OF SEDAN AND BUS BY ZONE

(Vehicle/Day)

| Zone | 1985 | | 2000 | | | |

5-6 Estimation of Vehicle Trip Generation of Goods Vehicles

The validity of the goods flow volume estimated for 1976 is checked in section 5-4-3 (8) and it is verified that the estimated future goods flow and its method can be adopted for future forecast purpose.

5-6-1 Forecast of Future Goods Flow between Jakarta and Other Regions by Modes of Transport

From analysis of past statistical data, it is seen that the goods flow between Jakarta and other regions correlates well with the per capita GRDP, and a generation model based on relation between goods flow and per capita is used for forecast of future goods flow. As for goods flow by modes of transport, the flow through the port is determined from the masterplan for Tg. Priok, by deducting 4% of the volume as intraport transfer volume and adding 10% thereof as flow volume through other ports. The share of air cargo is extremely small and is overlooked as negligible. The volume of rail flow is assured to grow proportional to the growth in per capita GRDP. The truck flow volume is determined by deducting the volume by sea and by rail from the total goods flow volume.

The resultant goods flow by modes of transport are as follows:

Table 5-20 Forecast of Future Goods Flow by Modes of Transport

| Year | By sea | By truck | By rail | Total |
|------|--------|----------|---------|---------|
| 1985 | 19,679 | 40,005 | 1,770 | 61,454 |
| 1990 | 25,661 | 65,487 | 2,120 | 93,268 |
| 2000 | 35,482 | 144,637 | 2,862 | 182,981 |

(unit: 1,000 tons/year)

5-6-2 Forecast of Future Goods Flow Volume from Production and Consumption of Major Commodity Items

It is assumed that the commodity items not produced in Jakarta in 1973 will remain not to be produced in future.

(1) Intra-regional goods flow

- 1) The intra-regional goods flow of food farm crops, livestock and dairy products is determined by production in Jakarta and that of fertilizers determined by consumption in Jakarta.

The production of the above items has been on a decrease, and taking an index of 100 for the year 1973, it is assumed that for the years 1985, 1990 and 2000 the indices will drop to 90, 70 and 30, respectively.

- 2) The intra-regional flow of fresh fish and meat is determined by production in Jakarta and that of textile, apparels and other household wares by consumption. The volume of flow is calculated as a growth from 1973 proportional to the growth in population.
- 3) Goods flow between Tg. Priok and Jakarta (Reference: Section 5-4-3, (6)).

Assuming as goods flow by rail between Tg. Priok and Jakarta, the future volume handled at the port is divided into that between the port and Jakarta and that between the port and other regions in the same proportion as that for 1973.

- (2) Goods flow between Tg. Priok and other regions (unadjusted)
The volume of flow between Tg. Priok and other regions is obtained by deducting the volume between the port and Jakarta from the total volume. However, adjustment will be subsequently made for the volume by rail.

(3) "Through" truck traffic volume

The future through truck traffic volume is determined as growing from the 1973 volume in proportion to the GRDP of Jakarta and the 1973 volume is calculated as growing from the 1972 volume obtained through B/M O-D, in proportion to the growth of truck traffic

across the Jakarta boundary from 1972 to 1973.

(4) Goods flow between Jakarta and other regions (unadjusted)
From the total volume of flow by truck and by rail in Table 5-20, the flow between Tg. Priok and other regions determined in Step (3) and two fold of the through volume determined in Step (4) are deducted to obtain the unadjusted total and subsequent adjustment for flow by rail is made to obtain the final volume.

(5) Adjusted goods flow between Tg. Priok and other regions
The volume of flow between Tg. Priok and other regions by rail is obtained by multiplying future total rail flow volume as shown in Table 5-20, by the percentage obtained from the proportion of the flow between Tg. Priok and other regions as established in (3) and the flow between Jakarta and other regions as established in (5). The rail flow volume is deducted from the total volume between Tg. Priok and other regions to obtain the adjusted total flow by truck.

(6) Adjusted goods flow between Jakarta and other regions
In the same manner as in Step (6), the rail flow volume is determined and the adjusted volume of flow by truck is obtained by deducting the rail flow portion from the total goods flow between Jakarta and other regions.

Based on the above-mentioned method, the volume of goods flow by truck is established as shown in Table 5-21. However, it is assumed that 50% of the goods flow for intra-region, as well as that between Tg. Priok and Jakarta and that between Tg. Priok and other regions, stop by the urban area of Jakarta and 30% of the flow between Jakarta and other regions stop by Jakarta.

Table 5-21 Forecast of Future Cargo Movement by Truck

(Unit: 1000 ton/year)

| | 1973 | 1985 | 1990 | 2000 |
|---|------------------|--------------------|--------------------|--------------------|
| IN - OUT | 4,868 | 28,145 | 49,913 | 122,195 |
| Tg. Priok - OUT | 3,643 | 9,210 | 12,162 | 17,038 |
| A Sub total | 8,511 | 37,355 | 62,075 | 139,233 |
| THROUGH | 97 | 277 | 407 | 801 |
| B Cargo movement between Inside & Outside JKT | 8,705 | 37,909 | 62,889 | 140,835 |
| (IN - IN) x 1.5 | (3,544) 5,316 | (8,752) 13,128 | (12,357) 18,536 | (23,275) 34,913 |
| (Tg. Priok-IN) x 1.5 | (4,278) 6,417 | (10,036) 15,054 | (13,087) 19,631 | (18,096) 27,144 |
| (IN - OUT) x 30% | 1,460 | 8,444 | 14,974 | 36,659 |
| (Tg. Priok-OUT) x 50% | 1,822 | 4,605 | 6,081 | 8,519 |
| C Intra JKT Cargo movement | 15,015 | 41,231 | 59,222 | 107,235 |
| D C x 2 | 30,030 | 82,462 | 118,444 | 214,470 |
| E A + D | 38,541 | 119,817 | 180,519 | 353,703 |
| F A + B + D | 47,246 | 157,726 | 243,408 | 494,538 |

- Note: 1) "IN" means cargo movement to and from inside D.K.I. Jakarta but exclusive of Tg. Priok.
- 2) "OUT" means cargo movement to and from outside D.K.I. Jakarta.
- 3) "THROUGH" means cargo movement passing through D.K.I. Jakarta.
- 4) The figures in parentheses show cargo movement regardless of any stop inside D.K.I. Jakarta.

5-6-3 Average Load of Trucks

The results of B/M surveys for trucks carried out at Tangerang, Cibinong and Bekasi are as listed below.

Table 5-22 Truck Traffic Observed at Tangerang, Cibinong and Bekasi

(unit: Veh/day)

| Year | Tangerang | Cibinong | Bekasi | Total |
|------|-----------|----------|--------|--------|
| 1971 | 1,442 | 1,351 | 3,041 | 5,834 |
| 1972 | 2,500 | 2,828 | 4,002 | 9,330 |
| 1973 | 2,548 | 3,779 | 4,089 | 10,416 |
| 1974 | 3,203 | 6,090 | 6,518 | 15,811 |
| 1975 | 3,225 | 6,900 | 6,592 | 16,717 |

On the other hand, the statistical data by Jakarta on the surveyed volume of goods flow through the three survey points of Kalideres, Pasar Rebo and Bekasi are available as follows.

Table 5-23 Goods Flow by Trucks

(unit: ton/year)

| Year | Kalideres | Pasar Rebo | Bekasi | Total |
|------|-----------|------------|-----------|-----------|
| 1971 | 542,825 | 678,096 | 559,504 | 1,780,425 |
| 1972 | 563,055 | 972,380 | 1,141,694 | 2,677,129 |
| 1973 | 753,142 | 1,274,750 | 1,677,193 | 3,705,085 |
| 1974 | 844,276 | 1,475,844 | 1,529,419 | 3,849,539 |
| 1975 | 1,002,283 | 1,574,354 | 1,986,017 | 4,562,654 |

Source: Statistical Year Book of Jakarta, 1976.

Taking the three similar locations for the above surveys to be the same, and assuming 250 working days in a year for trucks, the average tonnage of goods on board per truck is as follows:

Table 5-24 Daily Average Goods Tonnage by Truck

(unit: ton/veh. day)

| Year | Tangerang | Cibinong | Bekasi | Average |
|------|-----------|----------|--------|---------|
| 1971 | 1.506 | 2.008 | 0.736 | 1.221 |
| 1972 | 0.901 | 1.375 | 1.141 | 1.148 |
| 1973 | 1.182 | 1.349 | 1.641 | 1.423 |
| 1974 | 1.054 | 0.969 | 0.939 | 0.974 |
| 1975 | 1.243 | 0.913 | 1.205 | 1.092 |

The general trend of tonnage per truck may be said to be on the increase although it fell in 1974 before resuming an increasing trend.

In the forecast of future load per truck, the following points have to be taken into consideration.

- (1) The improvement of the capability of trucks.
- (2) The relaxation of load restriction due to improvement of bridges and roads.
- (3) A reduction in the rate of empty vehicles due to increase in goods flow.
- (4) The trend of reduction in vehicle size in the urban area due to restriction, and an increase in size as well as containerization of inter-regional trucks.

With full consideration of the above factors, the trend of changes in load of the trucks may be summarized as follows:

- (1) For inter-regional transport, the truck will increase in size and will have a decrease in rate of empty vehicles so that the average load per vehicle will maintain an increasing trend.
- (2) For urban transport, the vehicle size tends to be reduced, but this is offset by a reduction in rate of empty vehicles so that the average load will remain almost unchanged.

The average load per truck for the key years are therefore assumed as follows taking also in consideration the rate of empty vehicles.

Table 5-25 Forecast Future Goods Tonnage by Truck

(unit: tons/vehicle)

| Year | Intra-urban | Inter-regional |
|------|-------------|----------------|
| 1973 | 1.80 | 2.00 |
| 1985 | 2.20 | 2.70 |
| 1990 | 2.20 | 3.00 |
| 2000 | 2.20 | 3.50 |

Without consideration on the planning of cargo terminals, the daily average truck trips and trip ends are calculated as follows:

Table 5-26 Daily Average Truck Trips

(unit: trip/day)

| | 1973 | 1985 | 1990 | 2000 |
|---------------------------------|--------|---------|---------|---------|
| Intra-regional | 33,367 | 74,965 | 107,676 | 194,973 |
| Between Jakarta & other regions | 17,022 | 55,341 | 82,767 | 159,123 |
| Subtotal | 50,389 | 130,306 | 109,443 | 354,096 |
| Through traffic | 194 | 410 | 543 | 915 |
| Total | 50,583 | 130,716 | 190,986 | 355,011 |

Table 5-27 Daily Average Truck Trip Ends

(unit: veh/day)

| | 1973 | 1985 | 1990 | 2000 |
|--------------------------------|---------|---------|---------|---------|
| Total trip ends within Jakarta | 83,756 | 205,271 | 298,119 | 549,069 |
| Total trip ends in whole area | 101,166 | 261,432 | 381,972 | 710,022 |

5-6-4 Goods Trips that Utilize Cargo Terminal

The rate of usage of cargo terminal is assumed as follows:

Table 5-28 Rate of Utilization of Cargo Terminal

| | Rate of stop within Jakarta | Rate of utilization of cargo terminal | | |
|--------------------------------------|--------------------------------|--|------|------|
| | | 1985 | 1990 | 2000 |
| Between Jakarta & other regions | 30 % | 10% | 15% | 20% |
| Between Tg. Priok & Jakarta | 50 % | 5% | 10% | 15% |
| Between Tg. Priok & other regions | 50 % | 10% | 15% | 20% |
| Through traffic | - | 25% | 25% | 25% |

From the above table, the volume of cargo handled at the cargo terminal is calculated as follows:

Table 5-29 Volume of Cargo Stopping at Cargo Terminal

| | (unit: 1,000 tons/year) | | |
|--|-------------------------|-------|--------|
| | 1985 | 1990 | 2000 |
| Between Jakarta & other regions | 844 | 2,246 | 7,332 |
| Between Tg. Priok & Jakarta | 251 | 654 | 1,357 |
| Between Tg. Priok & other regions | 461 | 912 | 1,704 |
| Through traffic | 69 | 102 | 200 |
| Total | 1,625 | 3,914 | 10,953 |
| Air terminal utilization rate in total truck flow | 2.06% | 3.22% | 4.28% |

Therefore, taking into consideration the use of cargo terminal, the annual cargo trip end is summarized as shown in Table 5-30 and Table 5-31.

The truck trip ends of the port facilities of Tg. Priok are divided into zone 66 and Zone 6, and the trip ends for Zone 6 is assumed at one-tenth of that for Zone 66.

Table 5-30 Distribution of Cargo Movement to and from Cargo Terminal

(unit: 1,000 ton/year)

| | 1985 | | 1990 | | 2000 | |

| Grand Total | 83,951 | 128,348 | 256,527 |

Table 5-32 Future Trip Volume of Trucks

| | 1985 | | 1990 | | 2000 | |
|-------------------------------------|---------|----------------|---------|----------------|---------|----------------|
| | ton/veh | veh/day | ton/veh | veh/day | ton/veh | veh/day |
| Intra-regional | 2.2 | 46,348 | 2.2 | 67,554 | 2.2 | 130,771 |
| Between Tg. Priok and Jakarta | 2.2 | 34,447 | 2.2 | 43,896 | 2.2 | 59,270 |
| Between Tg. Priok and Terminal | 2.2 | 1,942 | 2.2 | 4,270 | 2.2 | 8,347 |
| Between Jakarta and Terminal | 2.2 | 2,986 | 2.2 | 7,908 | 2.2 | 23,695 |
| <u>Sub Total A</u> | | <u>85,723</u> | | <u>123,618</u> | | <u>222,083</u> |
| Between Tg. Priok and other regions | 2.7 | 12,963 | 3.0 | 15,000 | 3.5 | 17,536 |
| Between Jakarta and other regions | 2.7 | 40,446 | 3.0 | 63,556 | 3.5 | 131,272 |
| Between terminal and other regions | 2.7 | 3,206 | 3.0 | 6,724 | 3.5 | 16,173 |
| <u>Sub Total B</u> | | <u>56,615</u> | | <u>85,280</u> | | <u>164,981</u> |
| Through traffic | 2.7 | 308 | 3.0 | 407 | 3.5 | 687 |
| TOTAL | | 142,646 | | 209,305 | | 387,751 |

The total trip end by districts is therefore summarized as follows:

Table 5-33 Distribution of Truck Trip Ends by District

| District | (unit: veh/day) | | |
|---|-----------------|----------------|----------------|
| | 1985 | 1990 | 2000 |
| Tg. Priok (Zone 66) | 44,865 | 57,424 | 77,412 |
| Tg. Priok (Zone 6) | 4,487 | 5,742 | 7,741 |
| Terminal-1, (Zone 41) | 8,134 | 9,451 | 16,072 |
| Terminal-2 (Zone 31) | - | 9,451 | 16,072 |
| Terminal-3 (Zone 16) | - | - | 16,071 |
| <u>Intra-region (Zones 1 ~ 41)</u> | <u>170,575</u> | <u>250,448</u> | <u>475,779</u> |
| Out of DKI Jakarta (including through traffic) | 57,231 | 86,094 | 166,355 |
| Through traffic | 616 (308) | 814 (407) | 1,374 (687) |
| <u>*Total trip ends within Jakarta</u> | <u>228,061</u> | <u>332,516</u> | <u>609,147</u> |
| Grand Total | 285,292 | 418,610 | 775,502 |

* 2 x A + B

It is assumed that a cargo terminal will be constructed in Zone 45 by the year 1985, another in Zone 31 by 1990 and a third one in Zone 16 by 2000, and the cargo to be handled by cargo terminals is equally allocated to the terminals.

5-6-5 Truck Generated Volume by Zone

In splitting the total truck generated volume into individual zones, it is assumed that 40% of the inter-regional trips are divided in proportion to the population of the zones and the remaining 60% divided proportionally to each of industrial areas in the zones.

Table 5-34 Generation of Truck Trip Ends by Zone

(unit: veh./day)

| | Base T.E. | 1985 Facilities T.E. | Total | Base T.E. | 2000 Facilities T.E. | Total |

5.7 Estimation of Traffic Distribution

5-7-1 Method of Estimation of Traffic Distribution

In estimating the traffic distribution for the passenger vehicles, the gravity model method which is capable of reflecting the changes in travel time between zones due to changes in future road network is adopted. In estimating goods vehicles sufficient attention is paid on the major cargo handling facilities such as port, cargo terminal etc., and also on the connection between the urban Jakarta and other regions. The movement of cargo within Jakarta City, excluding the flow between the port and the city, is estimated with the gravity model method, in the same way as the passenger vehicle traffic.

5-7-2 Estimation of Future O-D Matrices

(1) The situation of the O-D matrices

In the calculation of the trip generation, particularly for the passenger vehicle traffic, it has been described in Section 5-5 that studies are made on the two patterns of landuse, namely the one is of concentration of business and commercial area at one point and the other is of dispersal to the periphery. However, from the points of improvement situation of the roads surrounding the CBD and also of the railway, it has been argued that in future it will be difficult to maintain a one point concentrated development pattern. The O-D matrices are therefore estimated based on the landuse pattern of dispersal to the periphery.

(2) Gravity model

The traffic distribution is performed by the Gravity Model and the parameters are obtained through an analysis of existing traffic data whereas the inter-zonal travel time is obtained by route search taking into consideration future changes in road network.

Gravity model:

$$T_{ij} = T_i \times T_j \times \frac{k}{D_{ij}^n}$$

where, T_{ij} = distributed traffic between zone i and zone j .

T_i = generated traffic of zone i.

T_j = generated traffic of zone j.

D_{ij} = required travel time between zone i and zone j.

n and k = coefficient varying with vehicle type as follows:

| <u>Vehicle type:</u> | n | k |
|----------------------|------|------------------------|
| Passenger vehicle | 1.00 | $1,047 \times 10^{-6}$ |
| Good vehicle | 1.09 | $8,128 \times 10^{-5}$ |

(3) Converging calculation

The converging calculation is performed to adjust the calculated total traffic distribution to agree with the generated traffic volume of the zones, and the O-D matrices of passenger car, bus and truck are determined separately after the converging process.

5-8 Traffic Assignment Calculation

5-8-1 Method of Assignment

Estimation of future traffic assignment is performed to obtain the estimated traffic volume that will utilize each section of the established road network and to make the necessary evaluation of the suitability of road network allocation, the capacity of the road network, and the balance of traffic volume. As described in section 5-1, in the traffic assignment for Jakarta City, if calculation is made for all combinations of alternative conditions in target years, road operation system, toll system and toll collection system, the number of cases will be too numerous in relation to the number of zones and the size of the road network, so that in the calculation by the computer, the following basic assignment method is used.

(1) Demand assignment

This is the assignment of all the zone-pair traffic volumes to the shortest route between two zones, and the results will be the desired traffic volume, or the volume of traffic demand on each road link.

(2) Actual assignment

The actual assignment is by a method that better represents the traffic situation than the demand assignment method. That is, the method takes into consideration the degree of traffic congestion on each link and allows for reduction in travel speed due to restriction in traffic capacity of the link. The concept of the traffic capacity limitation method (Q - V method) of traffic assignment is as shown in the following figure.

Traffic Capacity Limitation Method (Q - V method)

When the traffic volume is below Q_1 , a vehicle may be able to travel at the maximum travel speed (V_{max}), which is about 80% of the design speed of the road. When the traffic volume exceeds travel speed gradually decreases in pace with traffic volume increase until the volume reaches Q_{max} when the travel speed drops to the minimum speed V_{min} . In this study, based on the results of travel speed survey and the results of traffic count, the traffic capacity limitation conditions of the road network are divided into 20 different road type classifications as shown in Table 5-35.

In actual assignment, the assignment to the shortest route is done in the same way as in the demand assignment method and according to the case of the assignment, the traffic volume of the O-D matrices is divided into 5, 10 or 15 equal lots for assignment. In equal lotting, the traffic volume T_{ij} of a zone pair is divided into equal parts so that the volume of each zone pair is $\frac{1}{n} \cdot T_{ij}$. This volume is the assignment to the shortest route between the zones based on the travel speed on each link according to the conditions shown in Table 5-35. The next assignment is made according to modified Q-V conditions based on the results of the previously assigned traffic volumes on the shortest route. The shortest route is defined as the shortest time, including the toll converted into time for the zone pair.

Table 5-35 Traffic Capacity Limitation of Roads
in Q-V Traffic Assignment

| No. | Type of Road | Location | No. of Lanes | Km/h V ₁ | Veh/day Q ₁ | Km/h V ₂ | Veh/day Q ₂ |
|-----|----------------------------------|-----------|--------------|---------------------|------------------------|---------------------|------------------------|
| 1. | Ordinary road | Urban | 2 | 40 | 3,500 | 5 | 10,000 |
| 2. | " | " | 4 | 40 | 22,000 | 10 | 47,000 |

| 15. | Ring Road | Type A | 4 | 80 | 31,000 | 20 | 62,000 |
| 16. | " | Type B | 4 | 90 | 32,000 | 20 | 64,000 |
| 17. | " | Type C | 6 | 70 | 47,000 | 20 | 94,000 |
| 18. | " | Type D | 6 | 80 | 48,000 | 30 | 96,000 |
| 19. | Ramp | Type A | 2 | 40 | 12,000 | 15 | 24,000 |
| 20. | Ramp | Type B | 2 | 60 | 12,000 | 20 | 24,000 |

Note: V₁ indicates highest speed
V₂ indicates lowest speed
Q₂ indicates traffic capacity

(3) Items of calculation and compilation

The following items are the output after the traffic assignment by computer.

- 1) Required travel time for each link.
- 2) Travel speed for each link.
- 3) The assigned traffic volume after the assignment for each link.
- 4) The accumulated assigned traffic volume of assignments for each link.
- 5) Ring Road traffic volume between ramps.
- 6) Intra urban road traffic volume between ramps.
- 7) The breakdown list of O-D pairs using the major links.
- 8) Traffic volumes by directions at major intersections.
- 9) Travel route and required travel time for all zone pairs

The target years for traffic assignment are 1985 and 2000 and the vehicle types are passenger car, bus and truck.

5-8-2 Determination of Road Network for Traffic Assignment

(1) Town planning roads of Jakarta City

Besides the trunk road network described in section 2-4, there are also town planning roads planned in Jakarta City for the future road network. The road network for the purpose of traffic assignment basically includes all the trunk roads and the major town planning roads.

(2) Completion of the road network for traffic assignment

All section between intersections in the road network established in (1) above, is given link numbers and all intersections are given node numbers. The total links for the whole network is summarized in the table below and the map of the network is shown in Fig. 5-13.

Table 5-36 Summary of Links by Road Type

| Road type | Link Number | Number of links | Total link length |
|------------------------------|------------------|-----------------|-------------------|
| 1. Toll roads | No.1 to No.77 | 77 | 219.4 km |
| 2. Existing roads in Jakarta | No.101 to No.254 | 154 | 305.7 |
| 3. Planned roads in Jakarta | No.301 to No.339 | 39 | 115.4 |
| 4. Roads outside Jakarta | No.401 to No.449 | 49 | 644.3 |
| Total | | 319 | 1,284.8 km |

The road network by target year is determined for 1985 and 2000 according to the road improvement program described in Section 2-4-3.

5-8-3 Toll and Conditions

(1) Toll road

In the road network under analysis, 5 toll roads are included, and the toll roads included for traffic assignment are as follows:

Table 5-37 Toll Roads for Traffic Assignment

| Name of toll road | Number of links | Total length of links |
|---------------------------|-----------------|-----------------------|
| Ring Road | 11 | 46.8 km |
| Inter-urban Expressway | 15 | 30.1 |
| Jakarta-Tangerang Highway | 4 | 25.7 |
| Jagorawi Highway | 6 | 40.3 |
| Jakarta Cikampek Highway | 7 | 49.2 |
| Total | 42 | 192.1 |

(2) Toll rates for toll roads

The toll rate and toll system of the toll roads under analysis are determined as in Table 5-38 according to the analysis of benefits in Section 9-6. The toll for the section is converted into time and added to the travel time in the search for the
