## TECHNICAL REPORT CONTENTS

1.	Outline of the method of estimating traffic volume.	
1.1	Explanation of traffic terms -----	1
1.1.1	Trip -----	1
1.1.2	Division of the trip -----	1
1.1.3	O-D table -----	2
1.1.4	Traffic zone -----	3
1.2	General methodology of estimating the traffic flow	
1.2.1	Data collection -----	5
1.2.2	Traffic surveys -----	5
1.2.3	Analysis of present conditions -----	6
	(1) The basic unit method	
	(2) The growth rate method	
	(3) The regression method	
	(4) The simulation method	
	(5) General	
1.2.4	Determination of future land use -----	10
1.2.5	Proposals for the future traffic network -----	10
1.2.6	Estimation of future traffic demand -----	10
	(1) Trip production	
	(2) Trip generation and attraction	
	(3) Trip distribution	
	(4) Completion of the O-D table	
	(5) Traffic assignment	
1.2.7	Evaluation of the proposals for future traffic planning -----	13
2.	The procedure for completing the present O-D table	
2.1	Some of the main results from the traffic surveys ----	14
2.1.1	Owner-interview Survey -----	14
	(1) The vehicle-ownership situation	
	(2) The number of trips recorded in the internal areas of Penang Island and Province Wellesley	
2.1.2	Ferry Survey -----	18
2.1.3	Cordon-Line Survey -----	22
2.1.4	Screen Survey -----	24
2.2	The procedure for completing the present O-D table ----	25

JICA LIBRARY

1059714[4]

11 006

3.	Present traffic situation	
3.1	Some situation from the present O-D table -----	26
3.1.1	An out-line of the traffic movements -----	26
3.1.2	A break down of trip purpose -----	27
3.1.3	Average number of trips per day -----	33
3.1.4	Departure time and arrival time -----	34
3.1.5	The average number of passenger per vehicle -----	40
3.2	Present O-D table -----	41
4.	An analysis of the present traffic situation	
4.1	The attributes of vehicles owners -----	55
4.1.1	Form of ownership -----	55
4.1.2	The situation of ownership by area -----	56
4.1.3	The attributes vehicle owners -----	58
4.1.4	The characteristic by working place -----	63
4.1.5	Type of establishment and size of employment -----	66
4.1.6	Period of ownership and frequency of usage of vehicles --	67
4.2	Analysis of trip production -----	70
4.2.1	Internal trip -----	70
4.2.2	External trip and through trip -----	76
4.2.3	Traffic volume and number of vehicles -----	90
4.3	Analysis of trip generation and attraction -----	96
4.3.1	Trip generation and attraction -----	96
4.3.2	The classification of zones -----	102
4.3.3	Analysis of trip generation and attraction -----	106
4.4	Analysis of trip distribution -----	128
4.4.1	The territory of traffic flow -----	131
4.4.2	The time distance -----	139
4.4.3	The formulation of the trip distribution model -----	143
4.5	Traffic assignment -----	155
4.5.1	The procedure of traffic assignment -----	155
4.5.2	Road network model -----	156
4.5.3	The method of estimating traffic volume -----	162
4.5.4	Results of present traffic assignment -----	166
5.	The premise	
5.1	Population and employed population -----	169
5.2	Comparison Between Penang Island and Province Wellesley	176
5.3	Number of vehicles -----	181
5.4	Summary of the premise -----	190

6.	Estimation of future traffic demand	
6.1	Outline of the flow-chart for estimation and some definition -----	191
6.2	Estimation of Future O-D Table -----	196
6.2.1	Trip Production -----	196
6.2.2	Trip generation and attraction -----	203
6.2.3	Future O-D Table -----	211
6.2.4	Varification by person trip -----	228
7.	Estimation of Future Traffic Demand by Transport Plan	
7.1	Concept of the Transport Plan -----	229
7.2	The way of the Calculation -----	232
7.2.1	Control of Parking Demand -----	232
7.2.2	The comparison of transport plan in George Town -----	256
7.3	Estimation of future traffic demand by transport plan	
7.3.1	Number of total trips by transport plan -----	247
7.3.2	The comparison of transport plan in George Town -----	256
8.	Estimation of the Future Traffic Demand on Road Nerwork ---	260
9.	Assignment for the road network without Ferry -----	271

## LIST OF TABLES

Table 1.1	O-D table by the internal, external & through trip -----	1
Table 1.2	O-D table by 4 traffic zones -----	2

1 Outline of the method of estimating traffic volume.

1-1 Explanation of traffic terms.

Generally the Origin and Destination Table called O-D table is used when forecasting future traffic demand because this table can show the movements of vehicles among the zones. The movements of vehicles are called trips.

The concept of 'trip' and 'O-D table' are explained by using the following simple example.

1-1-1 Trip

The term 'trip' means the route taken by a vehicle from the origin to the destination.

A single trip has 2 trip ends. One trip end, the origin, is called the "trip generation" and the other, the destination, is the "trip attraction".

1-1-2 Division of the trip

The total number of trips in the study area is divided into the following 3 groups.

These 3 groups are shown in the following O-D table.

Table 1-1 O-D Table by the internal, external and through trip.

origin \ destination	internal area	external area
internal area	internal trip	outgoing trip
external area	incoming trip	through trip

 internal trip     external trip     through trip

i-1-1 O-D table.

The following O-D table shows an example where there are only 4 traffic zones.

Table 1-2 O-D table by 4 traffic zones.

destination origin		traffic zones				trip generation
		1	2	3	4	
traffic zones	1	t11	t12	t13	t14	$g^1$
	2	t21	t22	t23	t24	$g^2$
	3	t31	t32	t33	t34	$g^3$
	4	t41	t42	t43	t44	$g^4$
trip attraction		a1	a2	a3	a4	T

In this example t12 is the number of trips that start from zone 1 and arrive at zone 2.

$g^1$  ( $t_{ij} = t_{11} + t_{12} + t_{13} + t_{14}$ ) is the total number of trip ends that arrive at zone 1.

$t_{ij}$  is called 'trip distribution',  $g_i$  'trip generation' and  $a_i$  'trip attraction'.

Thus, it is evident that the total number of trip generation is the same as the total number of trip attraction.

$$T = g^1 + g^2 + g^3 + g^4$$

$$= a1 + a2 + a3 + a4$$

This total number of trip distribution is called 'trip production'. Eventually, the O-D table will show the volume of 'trip production', 'trip generation', 'trip attraction' and 'trip distribution'.

1-1-4. Traffic zone.

Zone codes are made up of the following 3 figures.

--- large zone (for the purpose of grasping the outline of traffic movement)

--- middle zone (the zone which is for practical use)

--- small zone (most detailed zone in this survey)

According to these zones, the internal area is divided into 8 large zones, 20 middle zones and 57 small zones.

Fig 1-1 Zone Map (middle zone)

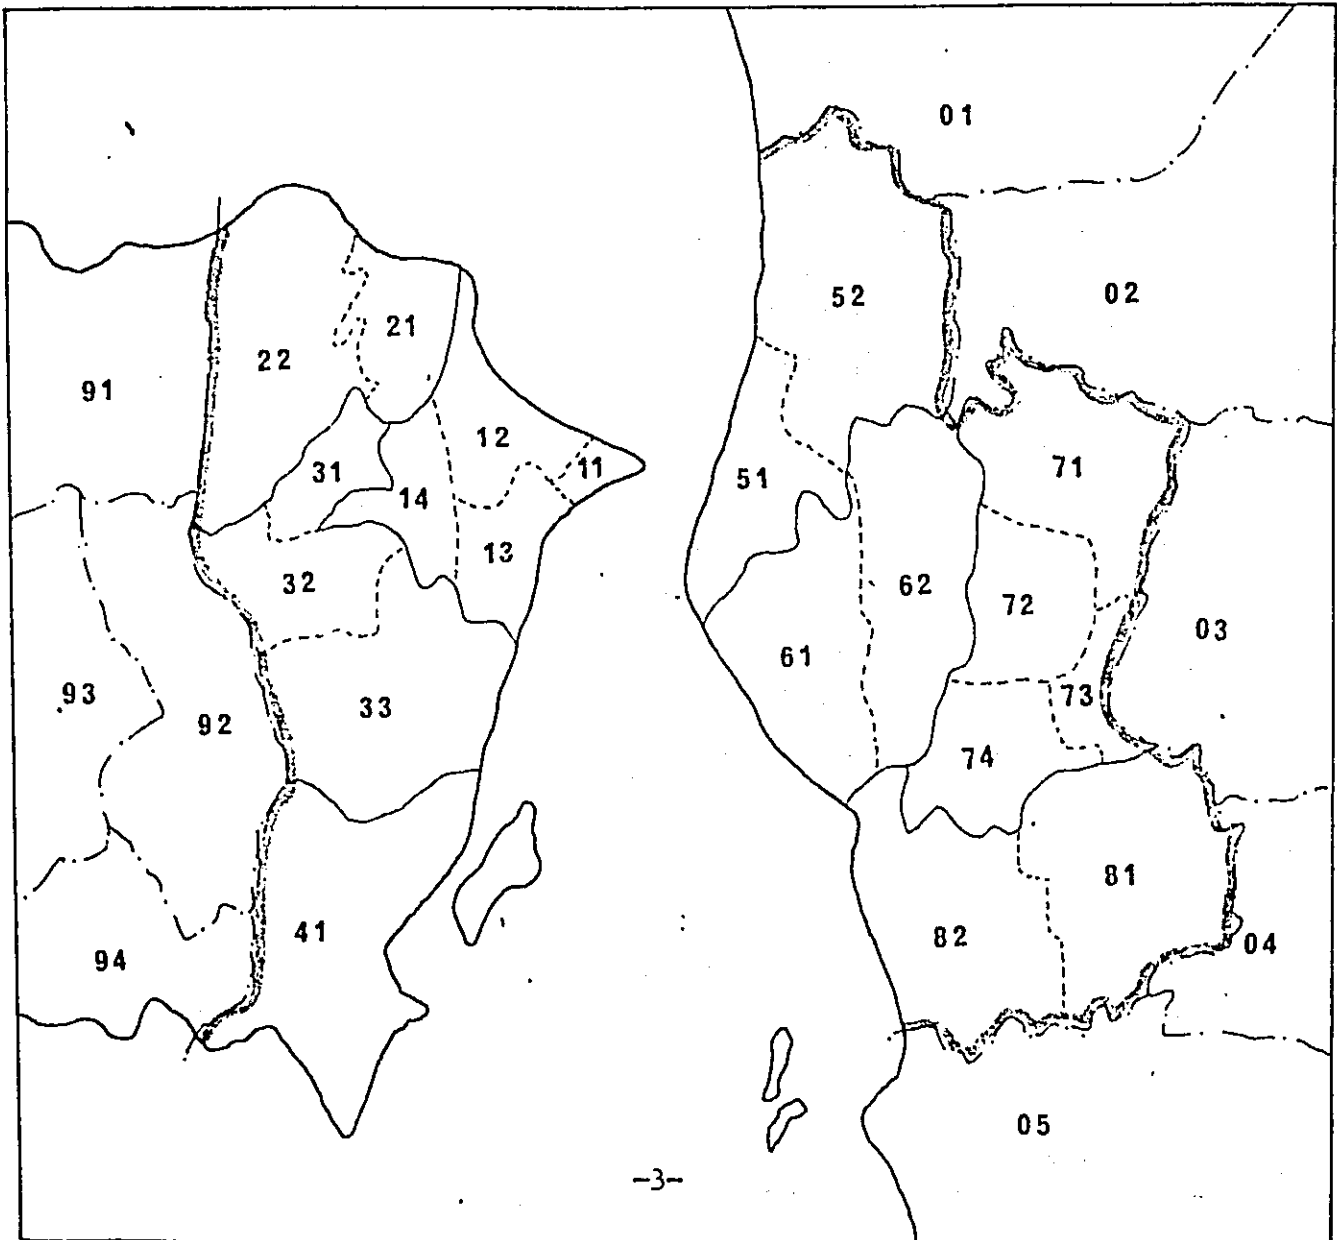

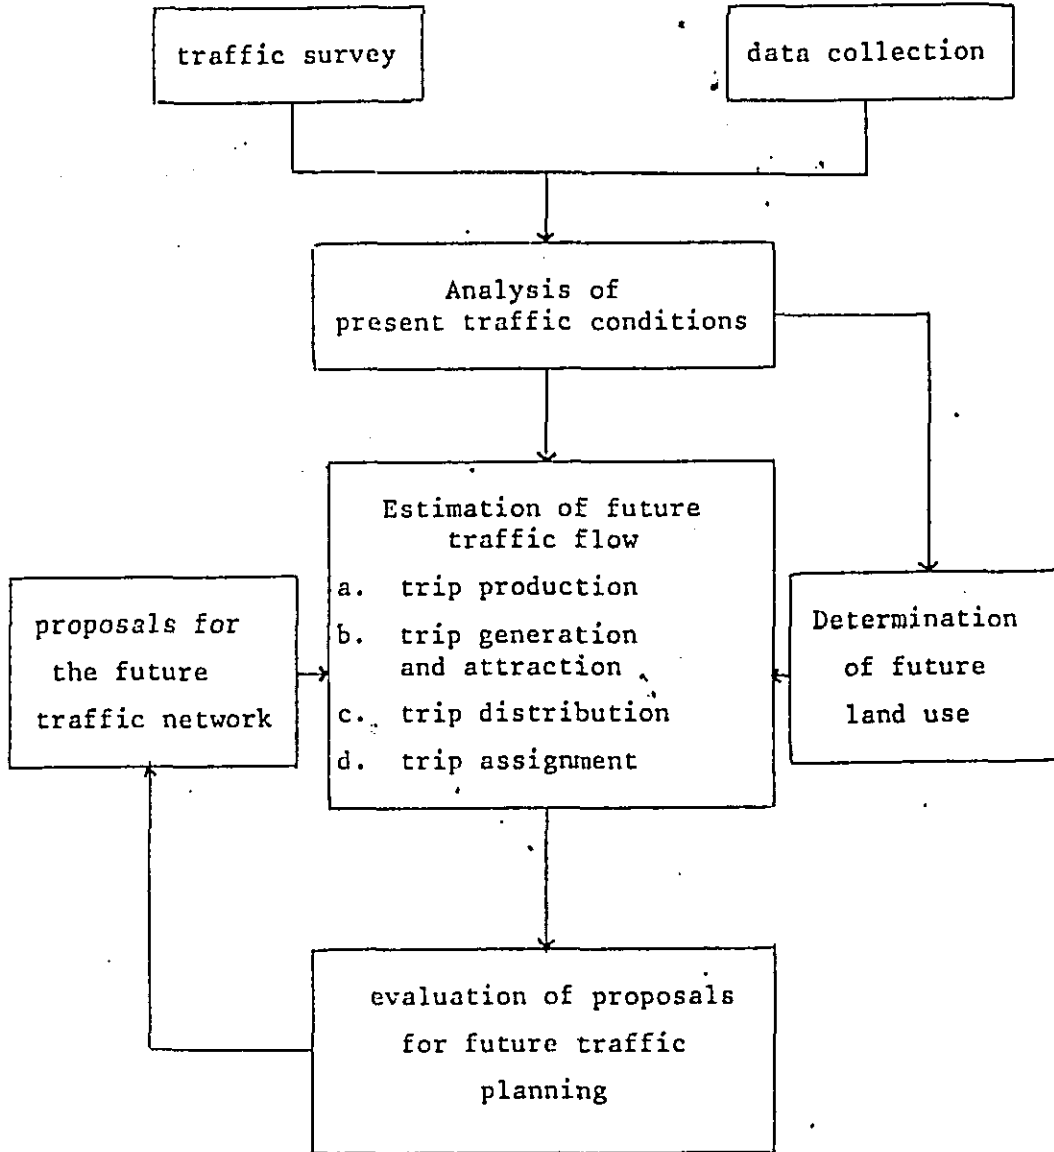

Fig 1-2 shows the main steps in the methodology of traffic planning most commonly used.

Fig 1-2 The methodology of traffic planning

The procedure starts with the collection of data and conducting traffic surveys which constitute the basis for the analysis of statistical relationships. Then the future traffic network which could best serve the expected land-use is outlined. There after the future flow in the alternative traffic network can be estimated through four steps, that is, trip production, trip generation and attraction, trip distribution and traffic and assignment. Sometimes modal split step is required between trip distribution and traffic assignment.

Finally the results are evaluated and any possible alterations of the traffic network are introduced. Usually the land-use pattern is considered fixed while the traffic network is considered a flexible variable. Here, the future traffic network is outlined and the land-use pattern which is likely to appear under the traffic network is estimate.

As such the traffic network has an impact far beyond the traffic conditions because, if the expected interaction between traffic network and land-use does exist, then we can control the urban development through traffic planning.

The following section discusses the main items in the previous flow-chart. (Fig. 1-2)

1-2-1

Data collection

The collection of data is mainly concerned with:-

- a. present land-use and land utilization rates.
- b. existing traffic facilities.

Data for the land-use and the land utilization rates are used as explanatory variables when relating to the number of trips to and from different zones. At the same time these data are important when the estimates of the future land-use are worked out.

Data for existing traffic facilities are used for the inventory of the corresponding supply of the facilities, the proposal for new transportation systems and to help to explain the observed trip patterns.

1-2-2

Traffic Surveys

The core of the traffic surveys is the home-interview survey which provides the survey area with the information mentioned below with regards to particular information on the households and the trips made by owners on the previous day.

The data collected are analysed in order to find relationships and trends which may form the basis for forecasts.

Usually the relationship are expressed in the use of some traffic models which apply to present traffic situations.

The traffic model is used for estimating traffic demand. Commonly, the types of traffic models are divided into the following 4 methods.

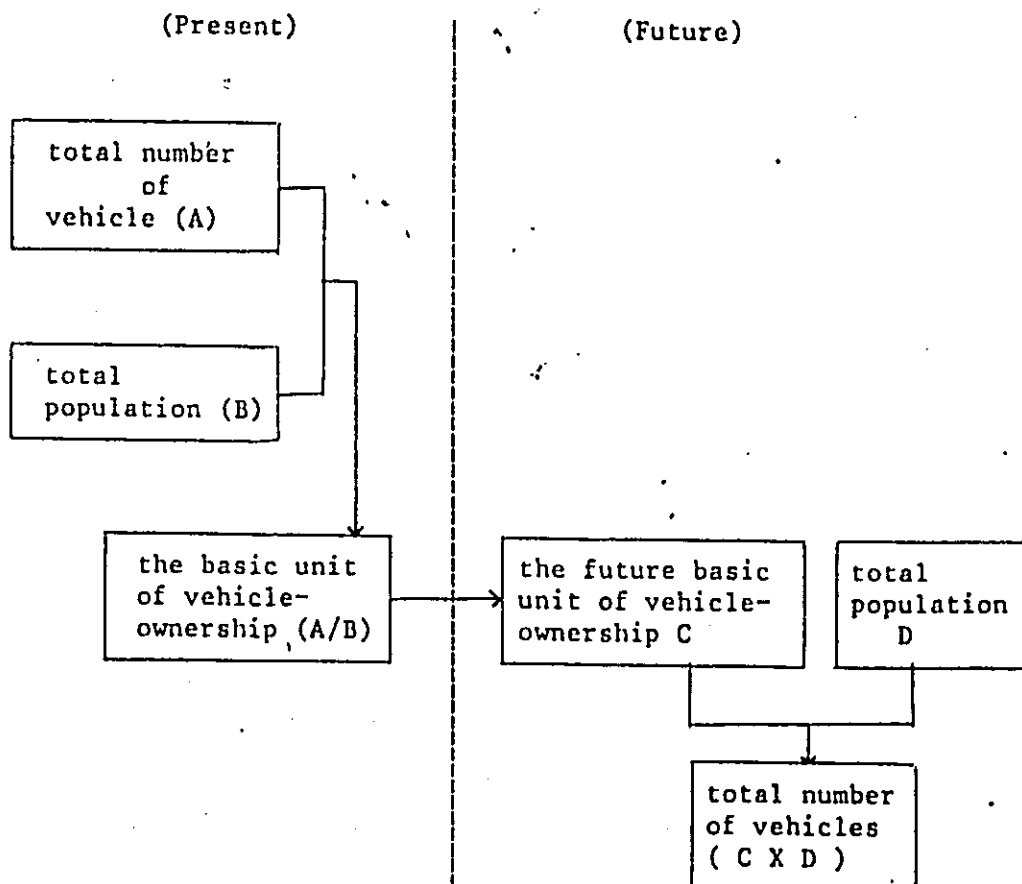

- (1) the basic unit method.
- (2) the growth rate method.
- (3) the regression method.
- (4) the simulation method.

(1) The basic unit method.

The basic unit is obtained by means of dividing the objective quantity by a certain unit. For example, the basic unit of vehicle-ownership is obtained by dividing the total number of vehicles by the total number of population or the total number of households.

In estimation work, we use this basic unit to estimate future objective quantity.

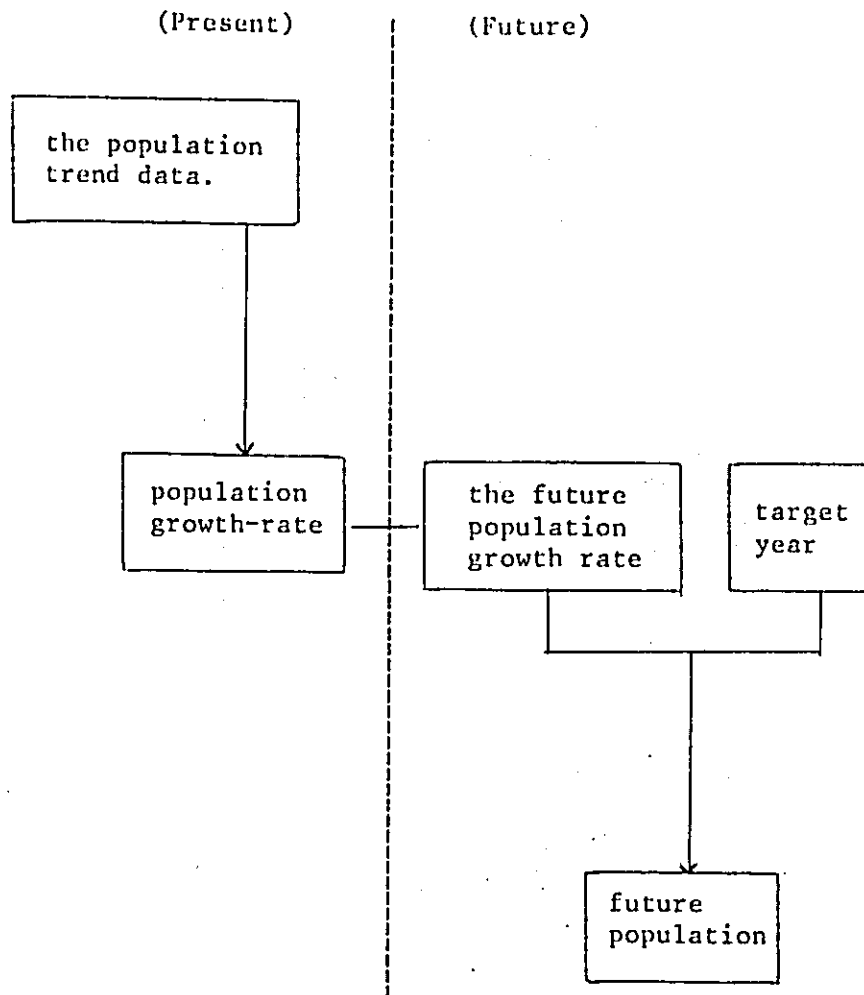

Example:

(2) The growth rate method.

The growth rate is obtained from various trend data, for example, the population projection data together with the data on the rate of population growth is very much used.

Example:

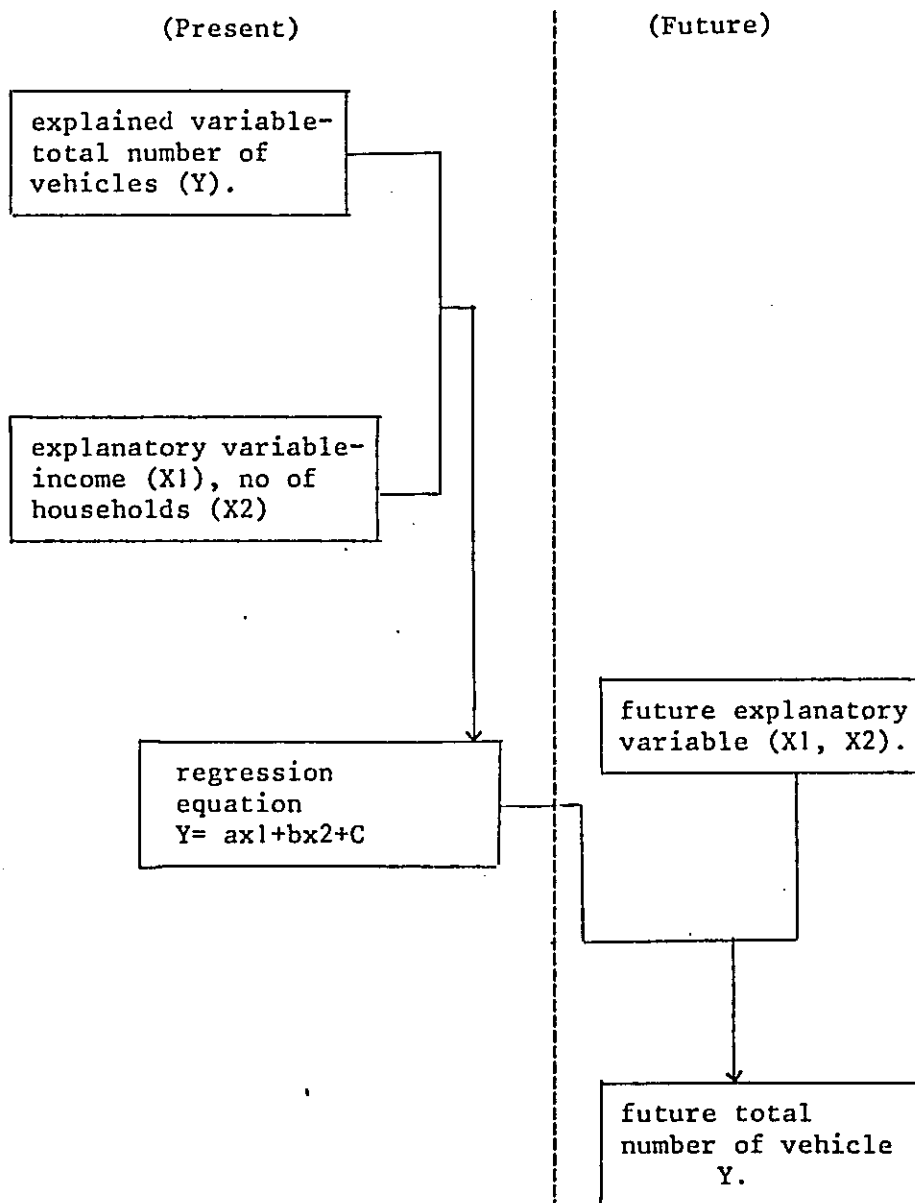

(3) The regression method.

This method makes use of the least square method to obtain the regression equation.

The explained variable is the unknown factor and the explanatory variables are the known factors, ie. the population figure and the area by land-use.

Example:

(4) The simulation method.

By using this method, we can obtain information on traffic phenomena, that is, the traffic flow at the roundabouts, the traffic flow on the roads and the traffic flow in the road network.

Some hypotheses of the actual flow is made and then the traffic flow is artificially created by using the computer.

(5) General.

Generally speaking, the following models are usually used in line with each step of the traffic estimation.

Table 1-3 Models used in the line with each step of the traffic estimation.

stage of estimation \ type of model	basic unit model	growth rate model	regression model	simulation model
trip production	0	0		
trip generation and trip attraction	0	0	0	
trip distribution			0	
traffic assignment				0

1-2-4 Determination of future land-use.

It is important to determine the future land-use because a knowledge of the future land-use pattern is a prerequisite in the estimation of traffic demand. It is a fact that the future population density is strongly related to the number of trip generations in the future. Therefore, it may rightly be said that the future land-use pattern will determine the future traffic demand.

1-2-5 Proposals for the future traffic network.

In order to obtain some guidelines in the preparation of the proposals for the future traffic network, an estimate of the existing capacity of the network when exposed to both the observed and the forecasted traffic is first made. A comparison between the "demand" and the "supply" on each link can be carried out.

The proposals for the traffic network usually emerge from the comparison, from policy objectives and from engineering experience and judgement.

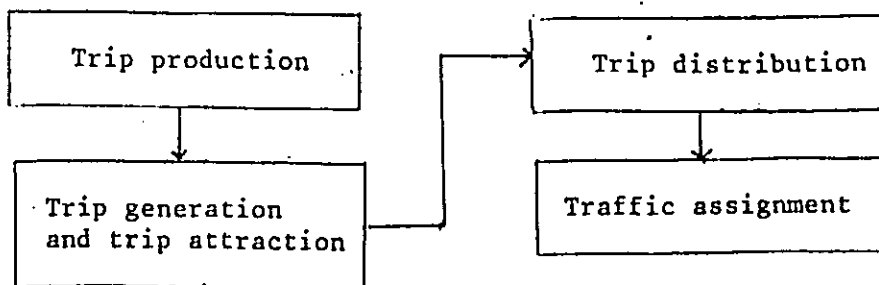

1-2-6 Estimation of future traffic demand.

The next step in the planning process is the estimation of the future traffic flow.

The data used are the proposed land-use figures and related figures (population, employment, etc.), the different proposals for the traffic network and the relationships and trends which have been developed from the traffic surveys.

The estimation consist of four steps.

The flow-chart is as follows:-

(1) Trip production.

This is the first step in the estimating of O-D tables. The purpose of this is to estimate the total number of trips in the study area. This is shown by the shaded portion in the following table.

D O		

As is usually done, trip production is estimated by multiplying the total number of vehicles by the unit trip production of each vehicle. The unit trip production used is obtained from the actual survey, that is the car O-D survey.

Another method which is used occasionally is the correlation formula which is calculated from the population figure, the number of vehicles, etc.

(2) Trip generation and trip attraction.

This is the estimation of the number of trips that start from and arrive at each traffic zone.

D O		

It is easy to understand this concept if we consider the purpose of each trip. For example, when the purpose of the trip is to get to the working place, a single commuter usually produce one trip. Therefore, the trip generation for this purpose is

related to the number of residents, number of employees, land-use area by utilization etc.

(3) Trip distribution.

This is the most complicated step in the estimation of future traffic demand because if there are 50 traffic zones, we must estimate for 2500 (50 x 50) pairs of trip distributions.

Many empirical formulae were formulated by many of our predecessors for the purpose of estimating the trip distributions. Among them, the gravity model is the most general method. Therefore, the concept of gravity model is introduced.

The fundamental formula of gravity model is shown as follows:-

$$T_{ij} = R \frac{g_i \times a_j}{t_{ij}^r}$$

$T_{ij}$  : trip distribution from zone i to zone j.

$g_i$  : trip generation from zone i.

$a_j$  : trip attraction to zone j.

$t_{ij}$  : time taken from zone i to zone j.

$r$  : coefficient of distance resistance.

$R$  : coefficient.

This is common sense, that is, the more  $g_i$  or  $a_j$  increases, the more the traffic volume between i and j will increase and, the shorter the distance from i to j become, the more the increase in volume of traffic.

This formula is applied to the "law of terrestrial gravitation" (Newton's Law).

These coefficients are estimated from the least square method applied to the relationship between the present O-D table (which is obtained from the car O-D survey) and the present time taken for each zone pairs.

(4) Completion of the O-D table.

Data on trip production, trip generation, trip attraction and trip distribution are required for completing the O-D table.

(5) Traffic assignment.

After the O-D table has been estimated, it is necessary to estimate the traffic volume on each road. This process involves some amount of simulation. First, we make a model of the road network, and then to the traffic volume of each zone pairs (as already forecasted in the O-D table) are assigned the road network according to the travel time between origin and destination.

It is commonly accepted that the travel time also includes the time spent whenever there is traffic congestion. For the purpose of actualizing the above-mentioned situation, the O-D table is sub-divided and the traffic assignment on each O-D table is sub-divided and the traffic assignment on each O-D table is executed repeatedly.

1-2-7

Evaluation of the proposals for future traffic planning.

When the future traffic flow in a network has been computed, overloaded parts or poorly utilized parts will be indicated. The necessary alterations are introduced and a new capacity for the the network will be carried out. This procedure is applied to each of the alternative proposals.

When the distribution of traffic on the network is obtained the total trip length and travel time is also computed. These figures, together with the construction costs constitute the basis for the economic assesment of the different proposals.

2

The procedure for completing the present O-D table.

For the purpose of grasping the traffic movements, various kinds of traffic surveys were carried out.

The present O-D table according to each vehicle type was completed using that data.

In this section, the main results of each traffic survey is explained firstly, and then the procedure for completing the present O-D table is explained.

2-1

Some of the main results from the traffic surveys.

Some traffic surveys were carried out in June 1979. They were the owner-interview survey, ferry survey, cordon-line survey and screen-line survey,.

First, some of the results of each traffic survey will be explained, then the method of completing the present O-D table will be shown.

2-1-1

Owner-interview Survey.

From the results of the owner-interview survey, information on vehicle owners and traffic movements can be obtained.

(1) The vehicle-ownership situation.

The number of vehicles and motorcycles registered with the R.I.M.V. in the state of Penang up to the end of May 1979 is shown in the following table.

Table 2-1 Number of vehicles and motorcycle.

Type of vehicle	Number
Car	61674
Van	3709
Medium Lorry	4461
Heavy lorry	7043
Taxi	474
Bus	1073
Total for vehicle	78434
Motorcycle	124984
Grand total	203418

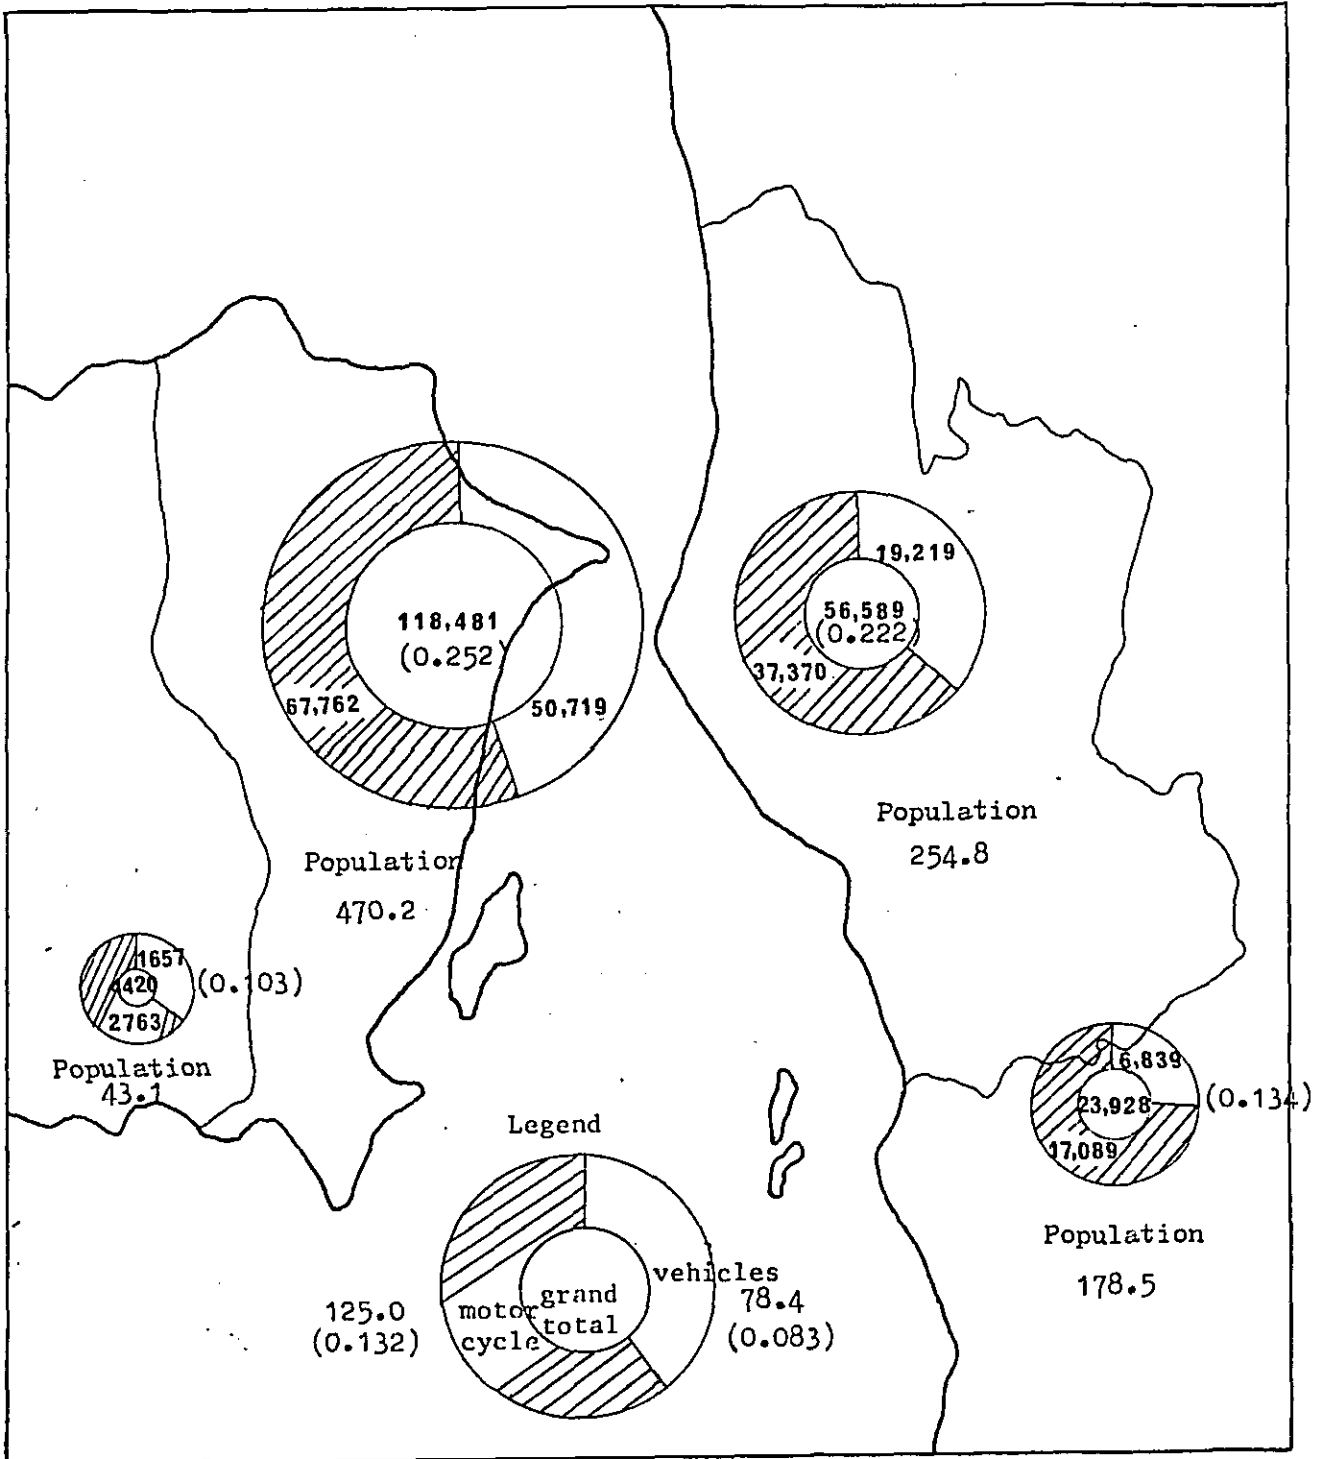

Population:  
946580 persons.

The registration of vehicles/motorcycles at the R.I.M.V. did not take into consideration the classification by area. Therefore the number of vehicles in the internal area was estimated by using the results of out owner-interview survey.

Table 2-2 The number of vehicles in the internal area.

Vehicles	Car	Van	Medium Lorry	Heavy Lorry	Taxi	Bus	Total	Motor cycle
Car								
Internal area	55956	3294	3671	5744	350	923	69938	105132
External area	5718	415	790	1299	124	150	8496	19852
Penang State	61674	3709	4461	7043	474	1073	78434	124984

Figure 2-1 The number of vehicle by area.

( ) : number of vehicle / population

(2) The number of trips recorded in the internal areas of Penang Island and Province Wellesley.

This survey traces the movements of vehicles in the internal areas of Penang Island and Province Wellesley.

The results are as follows:-

Figure 2-2 The number of trips in the internal areas  
(unit: trip per day)

The above figure shows that in Province Wellesley, trips made by motorcycles contribute to a large proportion of the trips generated, amounting to 66% of total number of trips. In Penang Island, on the other hand, trips by motorcycles contribute to 55% of the total number of trips generated. Thus, proportion of trips between vehicles and motorcycles is roughly one to one.

Ferry Survey.

The results of this survey provide information on the movements of vehicles and passengers between Penang Island and Province Wellesley.

The types of vehicles and the trip purpose of the drivers are as follows.

Table 2-3 The types of vehicles using Ferry.

Origin destination Vehicles trip purpose		From P.I. to P.W.	From P.W. to P.I.	Total	(Percentage)
C A R	going to work	1,235	553	1,788	(7.5)

-  going home

The distribution of vehicles and motorcycles which makes use of the ferry is as follows:-

Figure 2-4 : Iteration and attraction of vehicles which made use of the ferry.

2-1-3 Cordon-line Survey.

From this survey, the present situation of external trips and through trips was obtained.

This results for each direction of external trips (incoming) are as follows.

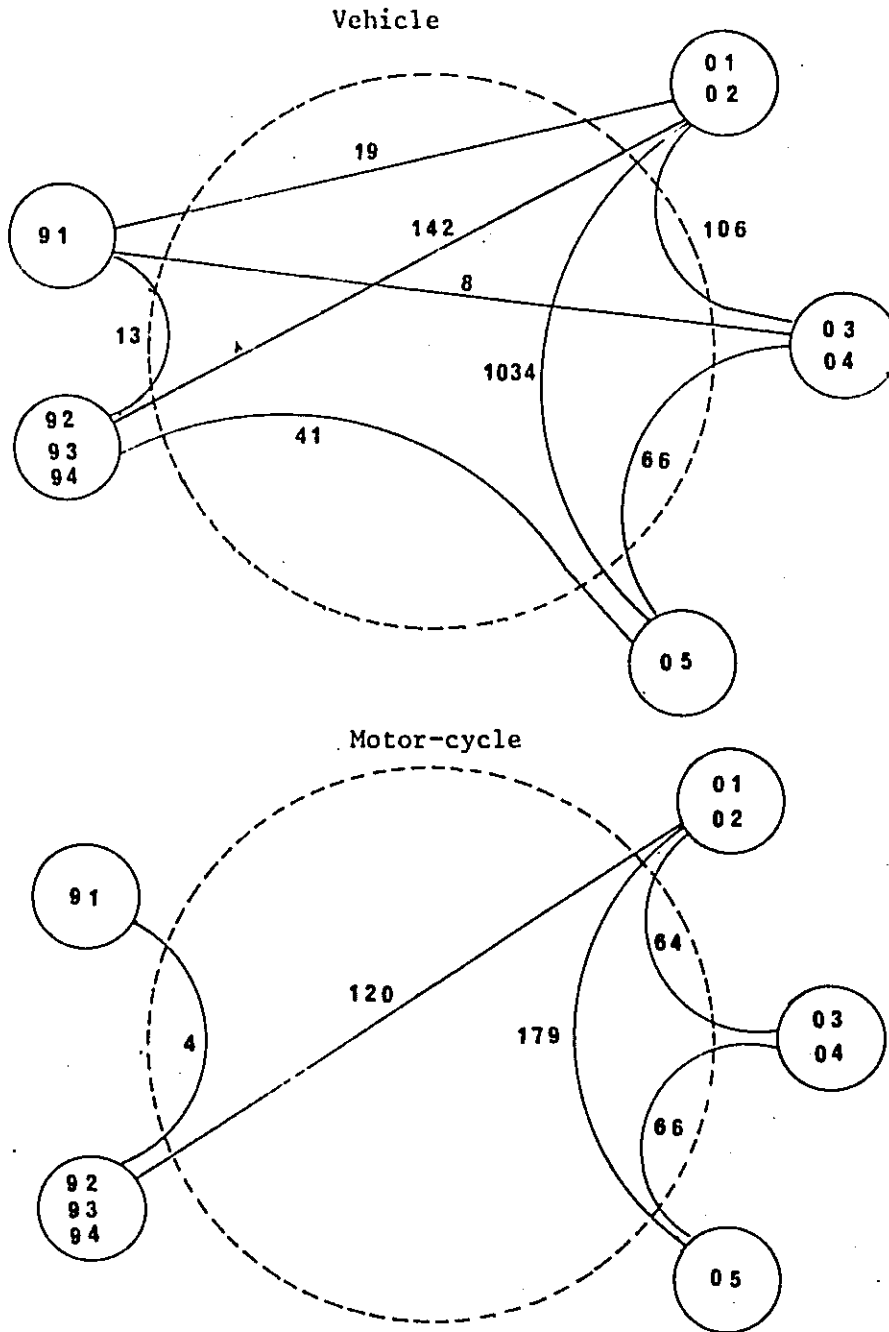

Figure 2-6 Number of external trips (in coming)

Direction		From	From	From	From	From	Total
		A	B	C	D	E	
CAR	going to work	121	324	911	273	386	2015

grand total		1486	3243	12150	5536	6966	29381

The result of traffic flow for through trip is as follows.

Figure 2-7 Traffic flow of through trip

Screen-line Survey.

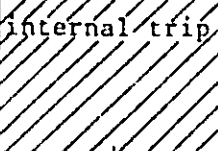

The results from this survey were used for the verification of the other traffic surveys. The traffic movements which were recorded by each traffic survey must correspond to the actual traffic volume on the screen line.

On checking the degree of accuracy, it was found that the results of those traffic surveys were very accurate and therefore can be used purpose of analyzing data from now on.

The procedure for completing the present O-D table

The present O-D table is completed from the following elements which are completed from the results of the following surveys.

Table 2-4 The O-D table and the elements.

O \ D		internal area		external area

LEGEND

owner-interview survey

ferry survey

cordon-line survey.

In the case of an overlap in the data collection, the following priority for the different surveys was used:-

- 1st priority data from the ferry survey
- 2nd priority data from the cordon line survey
- 3rd priority data from the owner-interview survey.

For example, the trips which made use of the ferry may have been interviewed at the ferry survey, cordon line survey and owner-interview survey. In this case, the data from the ferry survey was used to complete the O-D table. The basis for the above choice was based on the accuracy of each traffic survey.

3. Present traffic situation

3-1 Some situation from the Present O-D table.

3-1-1 An out-line of the traffic movements.

An out-line of the traffic movements is as follows :-

Figure 3-1 Number of trips for each travelling type.

The percentage for the different types of trips are shown in the following figure. From this, it can be seen that for internal trips, the ratio is higher for motor-cycles than for vehicles.

This means that the trip length of motor-cycles are shorter than those of vehicles, that is, motor-cycles are used more for short distance travelling.

Figure 3-2 The percentage for the each types of trips

3-1-2 A break down of trip purpose.  
The type of trip and the trip purpose are as follows.

Table 3-1 Type of trip and trip purpose

Type of trip		number of internal trip	number of external trip	number of through trip	Total
vehicle and trip purpose					
CAR	going to work	66378	4127	186	70691

	trip private	87810	5406	108	93324
	going home	155286	8020	442	163748
		397286	24317	770	422373
grand total		683419	58046	2455	743920

The trip purpose in detail is as follows:-

Table 3-2 The trip purpose in detail (unit: 1000 trip per day)

Broad Purpose		Car	Motor-cycle
Classification	Detailed classification		
Going to work	Going to work	57.2 (22.1)	111.9 (26.5)
	Going to school	13.6 ( 5.2)	9.5 ( 5.2)
Business trip	Business engagement	38.3 (14.8)	44.1 (10.4)
Private trip	Shopping/Marketing	13.5 ( 5.2)	21.8 ( 5.2)
	For food/Entertainment	18.6 ( 7.2)	34.1 ( 7.2)
	Social visit	24.5 ( 9.5)	35.0 ( 9.5)
	Other private trips	2.8 ( 1.1)	2.5 ( 1.1)
Going home	Going home	90.7 (35.0)	163.8 (38.8)
T O T A L		259.2 (100.0)	422.4 (100.0)

The Comparison between the trip purpose of cars and motorcycles is as follows:-

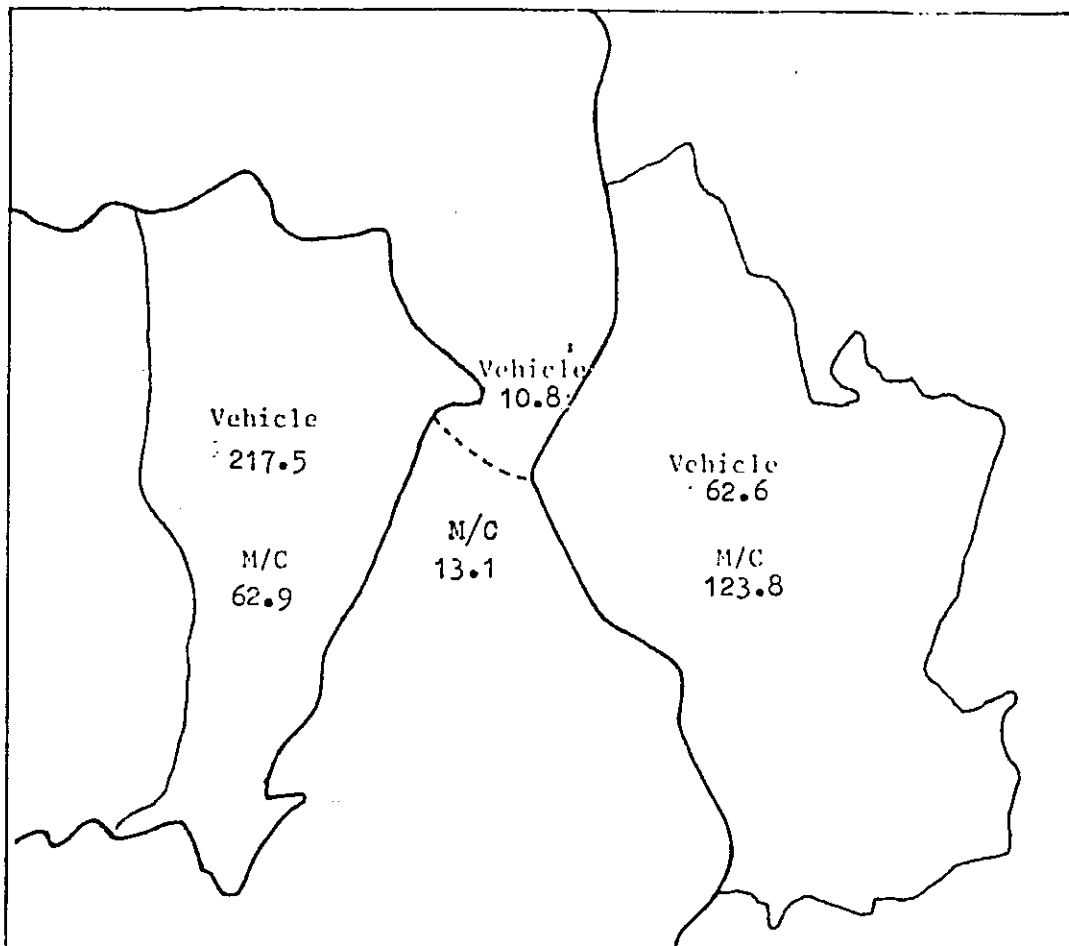

Going to work (22.1 %)	27.3	28.7	Going to work (26.5 %)
Going to school (5.2%)			Going to school (2.2%)
Business engagement (14.8%)	14.8	10.4	Business engagement (10.4%)
Shopping/marketing (5.2%)			Shopping/marketing (5.2%)
For food/entertainment (7.2%)			For food/entertainment (8.1%)
Social visit (9.5%)	23.0	22.2	Social visit (8.3%)
Other private trips (1.1%)			Other private trips (0.6%)
Going home (35.0%)	35.0	38.8	Going home (38.8%)
CAR			MOTORCYCLE

There is no conspicuous difference between the trip purpose of cars and motorcycles except in the case of business trips where the figures for cars are slightly higher than those for motorcycles.

Internal trips are divided into 3 types i.e. the trips which move into the internal areas of Penang Island, the trips which move into the internal areas of Province Wellesley and the trips which make use of the ferry.

Figure 3-3 Trip by Area.

(unit: 1000 trip per day)

The composition of the trip purpose for the 3 types of trips are compared in the following table.

Table 3-3 The composition of the trip purpose by area.  
(unit: 1000 trip per day)

Vehicles and trip purpose		Area	In Penang Island	At the ferry	In Province Wellesley
C A R	Going to work		51.5 (10.7)	1.8 (7.5)	12.5 (6.7)
	Business trip		23.2 ( 4.8)	2.2 (9.2)	9.0 (4.8)
	Private trip		41.6 ( 8.7)	2.3 (9.4)	10.5 (5.6)
	Going home		63.6 (13.2)	2.7 (11.2)	18.0 (9.7)
	Sub-total		180.1 (37.5)	8.9 (37.4)	50.9 (27.3)

Taxi			2.3 ( 0.5)	0.1 (0.3)	0.4 (0.2)
Bus			15.8 (3.3)	0.1 (0.5)	3.1 (1.7)
Sub total of vehicles			217.5 (45.3)	10.8 (45.2)	62.6 (33.6)
M O T O R C Y C L E	Going to work		74.3 (15.5)	5.2 (21.8)	34.3 (18.4)
	Business trip		28.9 (6.0)	0.8 (3.5)	11.3 (6.1)
	Private trip		58.6 (12.2)	2.4 (10.1)	27.5 (14.8)
	Going home		101.1 (21.0)	4.6 (19.4)	50.8 (27.3)
	Sub-total		262.9 (54.7)	13.1 (54.8)	123.8 (66.4)
Grand total			480.3 (100.0)	23.9 (100.0)	186.4 (100.0)

In Penang Island

At Ferry

In Province Wellesley.

3-1-3 Average number of trips per day.

From the owner-interview survey, the average number of trips per day can be obtained. Using the technical term in traffic studies, these figures are called "unit trip production". There are two types of unit trip production. One is the gross unit trip production while the other is the net unit trip production.

Some vehicles did not make any trips on the day of the interview. Therefore the former the gross unit trip production is the average trip per day of one vehicle which also includes zero (0) and the latter is the actual average number of trips per day of one vehicle.

These figures are as follows;

Table 3-4 Average number of trips per day (unit: trip per vehicle per day)

	The unit trip production (gross)	The unit trip production (net)	The % of zero number of trips
Car	3.98	4.25	6.3 %
Lorry	3.01	3.60	16.4 %
Taxi	8.07	8.07	0 %
Bus	20.6	20.8	0.9 %
(Vehicles)	4.09	4.43	7.7 %
Motor-cycle	3.78	4.01	5.7 %
All vehicles	3.90	4.17	6.5 %

Figure 3-4 The unit trip production. (unit: trip per vehicle per day)

3-1-4 Departure time and arrival time.

The departure time and arrival time of all vehicles with regard to trip purpose is shown in the following figure.

Figures for all trip purpose show that there are three peak hours in a day, that is, 8am - 9 am, 1pm - 2 pm and 5pm - 6 pm. These peak hours are caused by commuting trips, lunch hour trips and going home trips.

Figure 3-5 Departure time and arrival time

- - - ARRIVAL TIME

3-1-5 The average number of passengers per vehicle.

The average number of passengers (including the driver) per vehicle is as follows :-

In the case of the taxi, the above figure does not include the driver but includes trips without passengers too.

This 'no passenger trip' contributes to about 43 % of all the trips made by taxis. Thus, the actual average number of passengers per trip is 2.4 person ( $1.4/0.57$ ).

3-2

Present O-D table

The desired line and the O-D tables are shown in the following figures and tables.

4. The analysis of present traffic situation.

4-1 The attributes of vehicle owners

There are 69,990 vehicles and 105,100 motor-cycles in this study area. The bread down of these figures is as follows:

Table 4-1 The number of vehicles (unit : 1000 vehicles)

car	lorry	taxi	bus	total no. of vehicles	M/Cs.
59.3	9.4	0.4	0.9	69.9	105.1

In this section, some of the attrivutes of owners of vehicles obtained through the owner-interim survey, are shown

- a) Form of ownership of vehicles
- b) Sex
- c) Age
- d) Occupation
- e) Size of household
- f) Zone of working place
- g) Type of establishment
- h) Size of employment
- i) Period of ownership
- j) Frequency of usage for week

Note: The following types of vehicles, namely the lorry, taxi and bus are used only for specific purposes and owners of these types of vehicles are therefore different from other vehicle owners. Therefore in this analysis these types of vehicles are excluded.

4-1-1

Form of ownership

Of the two forms of ownership, the majority of vehicles and motor-cycles belong to the category of individual ownership, and the ratio for cars is 86% while that for motor-cycles is 97%.

Fig 4-1 Ownership of car by individual, company and government  
(unit : 1000 vehicles)

Ownership of motoroyole by individual, company and government  
(unit : 1000 vehicles)

4-1-2

The situation of ownership by area.

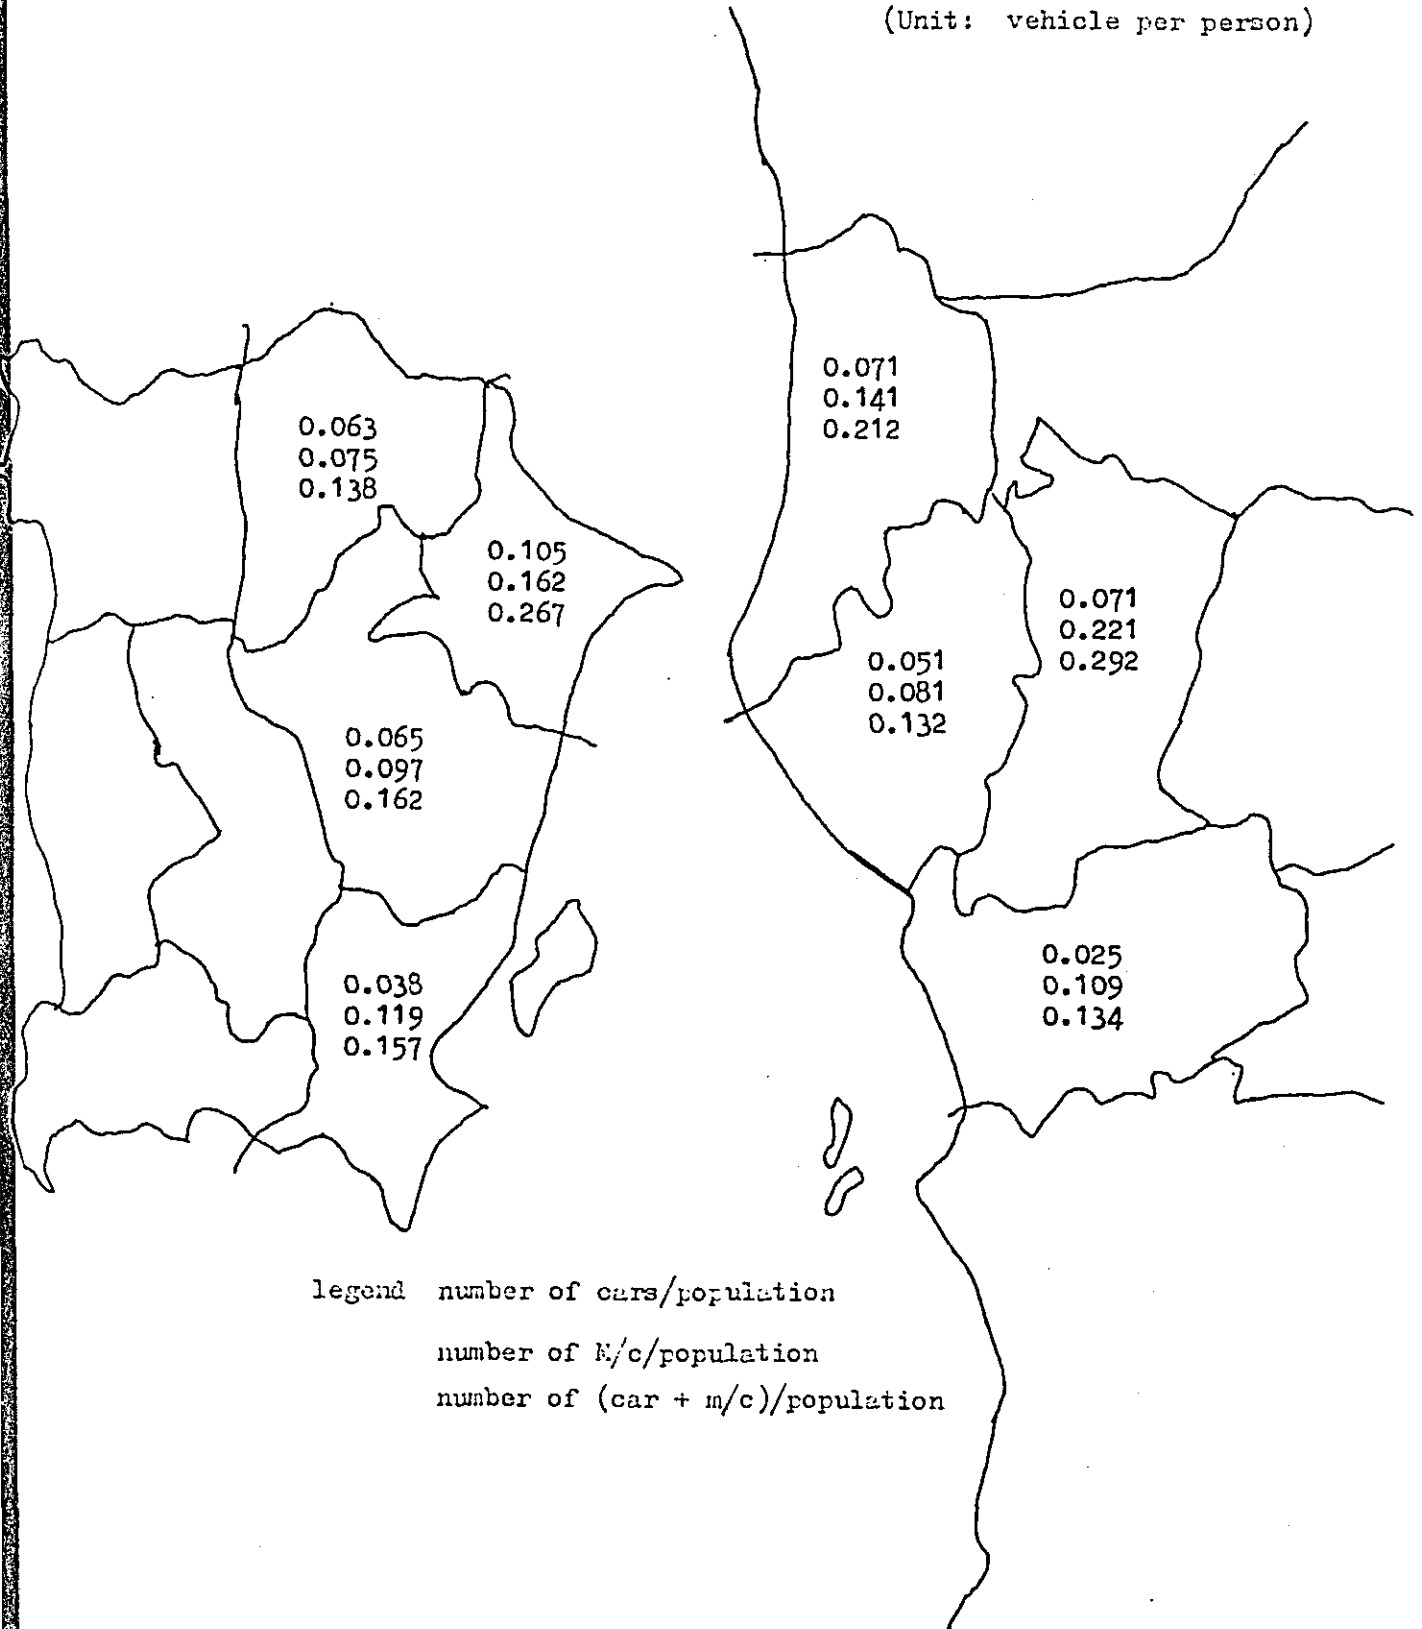

The difference in the situation of ownership by area is as follows:-

Table 4-2 number of vehicles by zone

Vehicles large zone	Number of cars (A)	Number of motor-cycles (B)	Total population (C)	Unit of vehicle-ownership		
				A/C	B/C	A+B/C
1	35864	55271	341220	0.105	0.162	0.267
2	1703	2017	26980	0.063	0.075	0.138
3	4756	7156	73630	0.065	0.097	0.162
4	1063	3318	27870	0.038	0.119	0.157
Penang Island	43386	67762	469700	0.092	0.144	0.236

Province Wellesley	15864	37370	230902	0.069	0.162	0.231
Study area	59250	105132	700602	0.085	0.150	0.235

Fig 4-2 Unit of vehicle ownership by zone

(Unit: vehicle per person)

legend number of cars/population  
number of M/c/population  
number of (car + m/c)/population

These figures show clearly the difference between the form of ownership in Penang Island and Province Wellesley.

In Penang Island, the unit of vehicle ownership of cars is higher, while in Province Wellesley, that of motor-cycles is higher.

These results show that urbanization process is progressing at a more rapid pace in Penang Island than in Province Wellesley.

4-1-3

The attributes of vehicle owners.

The attributes of individual vehicle owners obtained were:-

- 1) age
- 2) sex
- 3) size of household.

(1) Age and sex

The following figure shows the types of vehicles owned by age.

For the 40 years and above age group, the number of owner for cars and motor-cycles is almost the same, but in the age group of 20-29 year olds the number of owners for motor-cycles is 4.5 times more than that for cars.

This shows that the majority of motor-cycles is owned by the younger generation, that is, about 50% of the motor-cycles is owned by people belonging to the 29 years and below age group.

Fig 4-3 Type of vehicles owned by age (unit : 1000 persons)

More males than females own cars and motor-cycles as a means of transport. This is particularly true in the case of motor-cycle ownership as 94% of motor-cycles but 97% of cars are owned by males.

From our population study, the data for the present population by sex and age was collected. Using these data, the unit of vehicle ownership can be obtained. The results are shown in table 4-3.

The unit of ownership of cars in the age-sex category of 30-39 year old males is 0.378 cars per person and those of motor-cycles in the age-sex group of 20-29 year old males is 0.700 motor-cycles per person.

In the age-sex group of the 30-39 year old males, the unit of ownership of cars and motor-cycles is 1.034. This figure shows that some of these age-groups have 2 or more vehicle (that is, one car and one motor-cycle, 2 cars or 2 motor-cycles).

Table 4-5

Ownership of vehicles by age and sex group (unit : 1000 persons)

sex Age group	Male			Female			Total		
	Population	Cars	M/cs.	Population	Cars	M/cs.	Population	Cars	M/cs.
50 and above	46.6	7.1 0.152	7.5 0.161	48.1	1.2 0.025	0.1 0.002	94.7	8.3 0.088	7.7 0.080
40-49	33.0	9.7 0.294	13.7 0.415	33.6	2.2 0.065	0.8 0.024	66.6	11.9 0.179	14.5 0.218
30-39	41.8	15.8 0.378	27.4 0.656	43.8	4.7 0.107	1.7 0.039	85.6	20.5 0.239	29.2 0.341
20-29	58.3	7.4 0.127	40.8 0.700	62.1	2.7 0.043	4.6 0.074	120.4	10.1 0.084	45.4 0.377
18-19	16.2	0.1 0.006	4.3 0.265	17.4	0.0 0	0.7 0.040	33.6	0.2 0.006	5.0 0.149
total	195.9	40.1 0.025	93.6 0.478	205.0	10.9 0.053	7.9 0.039	400.0	51.0 0.127	101.6 0.253

Fig: 4-5 Ownership of vehicles by sex and age (unit : 1000 persons)

(2) Occupation

This attribute can be divided into two groups, viz. Those who are employed and those who are unemployed like students, housewives and the jobless.

The figures for this attribute is as follows:-

Table 4-4. Ownership of car and m/c by the employed and unemployed population. (unit : 1000 persons)

Employment status	Cars	M/cs.
employed	44.6	92.4
unemployed	6.4	9.2
total	510	101.6

From our population study, the ratio of the employed to the unemployed in 1979 is 31% (294000/996580) in Penang State. Therefore, the unit of vehicle ownership by occupation in the study area is as follows:-

Table 4-5 Unit vehicle possession of the employed and unemployed population. (unit : 1000 persons)

Employment status	Population	No. of vehicle		Unit vehicle possession		
		Car	M/c.	Car	M/c	Total
employed	224.4	44.6	92.4	0.199	0.412	0.611
unemployed	499.5	5.4	9.2	0.011	0.018	0.029
total	723.9	51.0	101.6	0.070	0.140	0.210

From this table, it can be seen that the unit of vehicle ownership is 0.199 car and 0.412 motor-cycle per employed worker.

60% of the employed make use of cars and motor-cycles as their means of transport instead of using public transport.

Fig: 4-6 Ownership of vehicles by type of occupation (unit : 1000 vehicles)

(3)

Size of households by type of vehicles

In small households (i.e those having between 1-4 people), the ratio of cars to motor-cycles is almost 1 to 1, whereas at large households, the ratio is 1 to 4.

Fig: 4-7 Size of Household (unit : 1000 vehicles)

4-1-4

The characteristic by working place

The difference in the situation of ownership by working place is as follows:-

Table: 4-6 Situation of ownership by working place

large zone	Number of cars (A)	Number of motorcycles (B)	Employment (C)	Unit of vehicle ownership		
				A/C	B/C	A+B/C
1	20.7	38.4	83.4	0.247	0.458	0.705
2	0.5	1.7	3.5	0.143	0.486	0.629
3	7.2	11.2	30.4	0.237	0.368	0.605
4	1.6	5.0	11.0	0.145	0.455	0.600
Penang Island	30.0	56.3	128.6	0.233	0.438	0.671
5	7.7	16.0	44.7	0.172	0.358	0.530
6	1.8	6.7	21.9	0.082	0.306	0.388
7	4.9	12.3	23.8	0.206	0.517	0.723
8	0.2	1.2	5.5	0.036	0.218	0.254
Province Wellesley	14.6	36.1	95.8	0.152	0.377	0.529
Study area	44.6	92.4	224.4	0.199	0.412	0.611

Note: The actual size of employment in the study area in 1979 is 237,290. However, in this table the figure is for those living and working in the study area.

Fig 4-8 Ownership of vehicles by zone of working place (unit : 1000 vehicles)

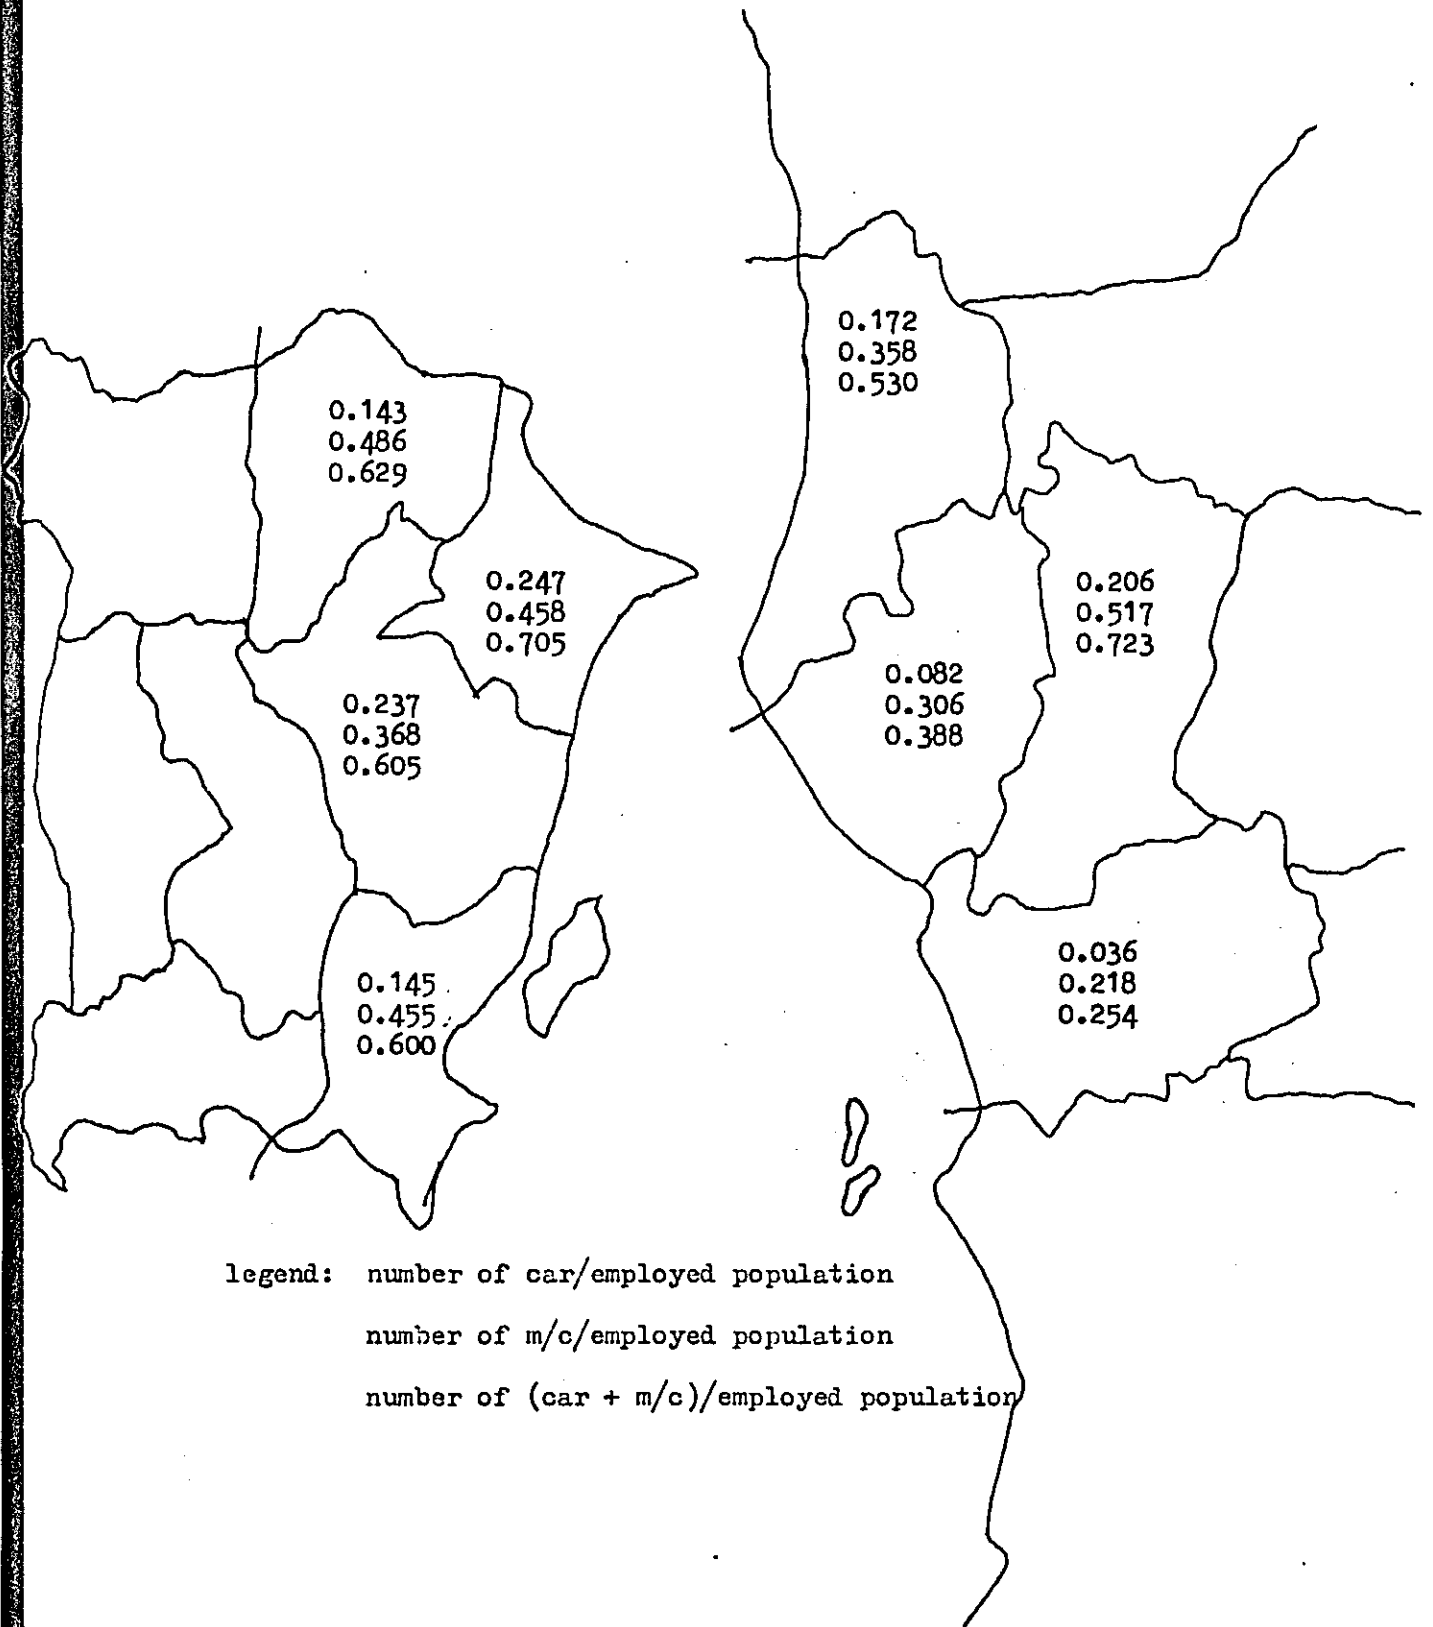

Fig. 4-9 Unit of vehicle ownership by zone of working place

legend: number of car/employed population  
number of m/c/employed population  
number of (car + m/c)/employed population

4-1-5 Type of establishment and size of employment

The ratio of cars to motor-cycles is almost 1 to 1 at government and finance/banking establishments.

Fig: 4-10 Ownership of vehicle by various types of establishment (unit : 1000 vehicles)

Fig: 4-11 Vehicles owned by various sizes of employment (unit : 1000 vehicle)

4-1-6

Period of ownership and frequency of usage of vehicles.

The majority of cars vehicles and motor-cycles are those owned for only 1-2 years, contributing to 49% and 46% of the totals respectively. This shows that the rate of possession of cars is slightly more rapid than motor-cycle.

Fig: 4-12 Period of Ownership (unit : 1000 vehicles)

The percentage of car and motor-cycle owners who use the car and motor-cycle daily is 75% and 80% respectively. Only 2.4% and 1.6% of car and motor-cycle owners respectively use the vehicles for 2 days or less per week.

Fig: 4-13 Frequency of usage per week (unit : 1000 vehicles)

Analysis of trip production

The total number of trips in this study area is divided into the following 3 groups.

In this section, the analysis are carried out separately according to above-mentioned trip type.

Internal trip

## (1) The unit trip production

From the O-D table, we can obtain the unit trip production of each vehicle in the internal area.

Table: 4-7 The unit trip production

VEHICLE AND TRIP PURPOSE		NUMBER OF VEHICLES AND MOTORCYCLES IN INTERNAL AREA	NUMBER OF INTERNAL TRIPS	THE UNIT TRIP PRODUCTION (TRIP PER DAY)
CAR	going to work	-	66378	(1.12)
	business trip	-	33428	(0.56)
	private trip	-	53060	(0.90)
	going home	-	83171	(1.40)
		59250	236038	(3.98)
	lorry	9415	28381	(3.01)
	taxi	350	2723	(8.07)
	bus	923	18987	(20.0)
VEHICLE		69938	286133	(4.09)
MOTOR-CYCLE	going home	-	113412	(1.08)
	business trip	-	40907	(0.39)
	private trip	-	83710	(0.84)
	going home	-	155286	(1.48)
		105132	379286	(3.78)
grand total		175070	683419	(3.90)

Average number of trips per day in the internal area are as follows :-

Fig: 4-14 . Average number of trips (gross)

These figures include "vehicles of no trips".

The percentage of "vehicles of no trips" is as follows :-

Fig: 4-15 The percentage of "vehicles of no trips"

Therefore the actual average number of trips per day of one vehicle is as follows :-

Fig: 4-16 The actual average number of trips (net)

(unit; trips per day)

These unit trip production by type of vehicle can be classified by characteristic of user. Therefore, using the category of form of ownership, sex, age and occupation, the unit trip production by characteristic of user are shown next table.

Table 4-3 Unit trip production by characteristic of user

		CAR	MOTORCYCLE
Form of ownership	Individual	3.92	3.74
	Company and Government	4.33	4.83
	Average	3.98	3.78
Sex	Male	3.95	3.78
	Female	3.79	3.29
	Average	3.92	3.74
Age	50 and above	3.77	3.80
	40 - 49	4.03	3.65
	30 - 39	3.92	3.75
	20 - 29	3.90	3.75
	Below 19	4.29	3.75
	Average	3.92	3.74
Occupation	Administrative and Managerial	4.17	3.69
	Professional and Technical	4.00	3.88
	Clerical	3.80	3.98
	Sales work	3.96	3.91
	Service work	3.85	3.74
	Factory, construction and General labour	3.60	3.58
	Agriculture	3.45	3.67
	Student	3.90	3.41
	Housewife	4.10	3.54
	Unemployed	3.66	3.33
	Average	3.92	3.74

It seems that there are no particular difference by characteristic of owner. All of the unit trip production by characteristic are included within 4.3 - 3.6 for car and 4.0 - 3.2 for motorcycle.

Next figure shows the distribution of number of trips. From this figure, we can find that the cars made only 2 trips per day are 25.8% and the motorcycles are also 29.2%.

The most number of cars made 4 trips per day at 26.7% and the most number of motorcycles made 4 trips per day at 32.2%. The percentage of number of cars which made 4 trips and more trips per day is 65.4% and the percentage of number of motorcycles which made 4 trips and more trips per day is 72.4%. Therefore, more than half of cars and motorcycles are usually made 4 and more trips per day.

Fig: 4-17

The distribution of number of trips

4-2-2

External trip and through trip.

Regarding external trip and through trip, the following data were obtained.

Figure. 4-18 Traffic flow of external trip.

However, these data only concerned with the present situation. For the purpose of analysing long-distance trips, data which cover a wider area are required.

The Federal route 1 and the East-West Highway study are reviewed, after that, the method to be chosen for the the estimation of long-distance trips will be considered.

(1) Feasibility study between Alor Star and Changkat Jering.

This study area covers parts of Kedah, Penang and Perak.

PRE - CONDITIONS.

Forecasts of future growth of the following elements were prepared as premises in estimating future travel demand.

- i) Population
- ii) Employment
- iii) Number of vehicles

i) Population

An average natural annual growth-rate of 2.7% is used for the population projection of the study area. However, due to the emigration of people from the study area, the growth rate has been adjusted to 2.4%, for the 21 year period from 1970 to 1991.

Table 4-9 Employment (unit: 1000 persons)

	Population	average annual growth rate (percent)
1970	1631.7	2.8
1981	2207.4	2.0
1991	2694.5	1.9
2001	3254.8	

ii) Employment

Due to the growth of the industrial (ie. mining and manufacturing), agricultural, construction, utilities, commercial, transport and services sectors, the Study Areas's employment is estimated to increase from 568,100 in 1978 to approximately 978,100 in 2001.

Table: 4-10 Employment (unit: 1000 persons)

	employment
1978	568.1
1981	642.9
1991	848.0
2001	978.1

iii) Number of vehicles

Vehicle ownership is expected to grow at a faster rate than population growth and the margin between all the states will diminish over the year 1980 - 2000.

Table: 4-11 Number of Vehicles (unit: 1000 vehicles)

		1978	1981	1991	2001
Kedah and Perlis	car (A)	33.0	50.0	102.0	152.0
	other vehicle	10.4	12.4	21.1	30.1
	m/c (B)	109.1	127.0	198.8	225.0
Penang	car (A)	63.8	74.0	120.0	169.0
	other vehicle	12.9	16.2	26.0	36.4
	m/c (B)	123.0	133.8	184.0	216.7
Perak	car (A)	76.3	97.7	168.0	240.0
	other vehicle	18.4	22.1	36.7	51.3
	m/c (B)	183.0	221.0	311.0	352.9

B.

Methods of estimation

The computer modelling technique with some refinement is used for traffic forecast in this study.

The models used are:-

- i) Highway Network Model.
- ii) Highway Trip Model.

The inputs of these models are data on travel pattern, travel time and roadway characteristic. These data were obtained from surveys.

i) Highway Network Models.

Computer simulation of the roadway network in the study area was developed for each study alternative tested. This network model include geographic distance between locations, average free-travel speeds and capacity data.

The current highway network (base-year Existing Network) was simulated as the first step in the modelling process.

Generated traffic was estimated by using a family of curves which related the magnitude of traffic induced to the proportion of travel time saved on a given trip.

The net effect of generated and degenerated traffic on the road system of the Study Area is an additional of 11984 trips in 2001 on the improved section of Route 1.

d) Traffic assignment.

Estimated use of the proposed improvement under study and the entire roadway system of the Study Area was derived from computer processing of appropriate combinations of network and trip tables.

Traffic was assigned to roadway links of the highway network model using the capacity restraint technique.

B. Results of traffic estimation

The existing unimproved route I has 61,500 trips as shown in the base year (1978) trip table. Regarding the 1981 trip forecast, the tables show the unimproved Federal Route I having 80800 trips while the network with Federal Route I improved has 21,100 trips. The growth rate over the 4 year period are 31.4 % and 31.9 % respectively. By 2001, traffic volume, are forecasted to increase by 129.6% even if Federal Route I remained unimproved, and by 143.5 % if Federal Route I (Butterworth - Alor Star/Jitra section) is improved.

SUMMARY OF TRIP TABLE

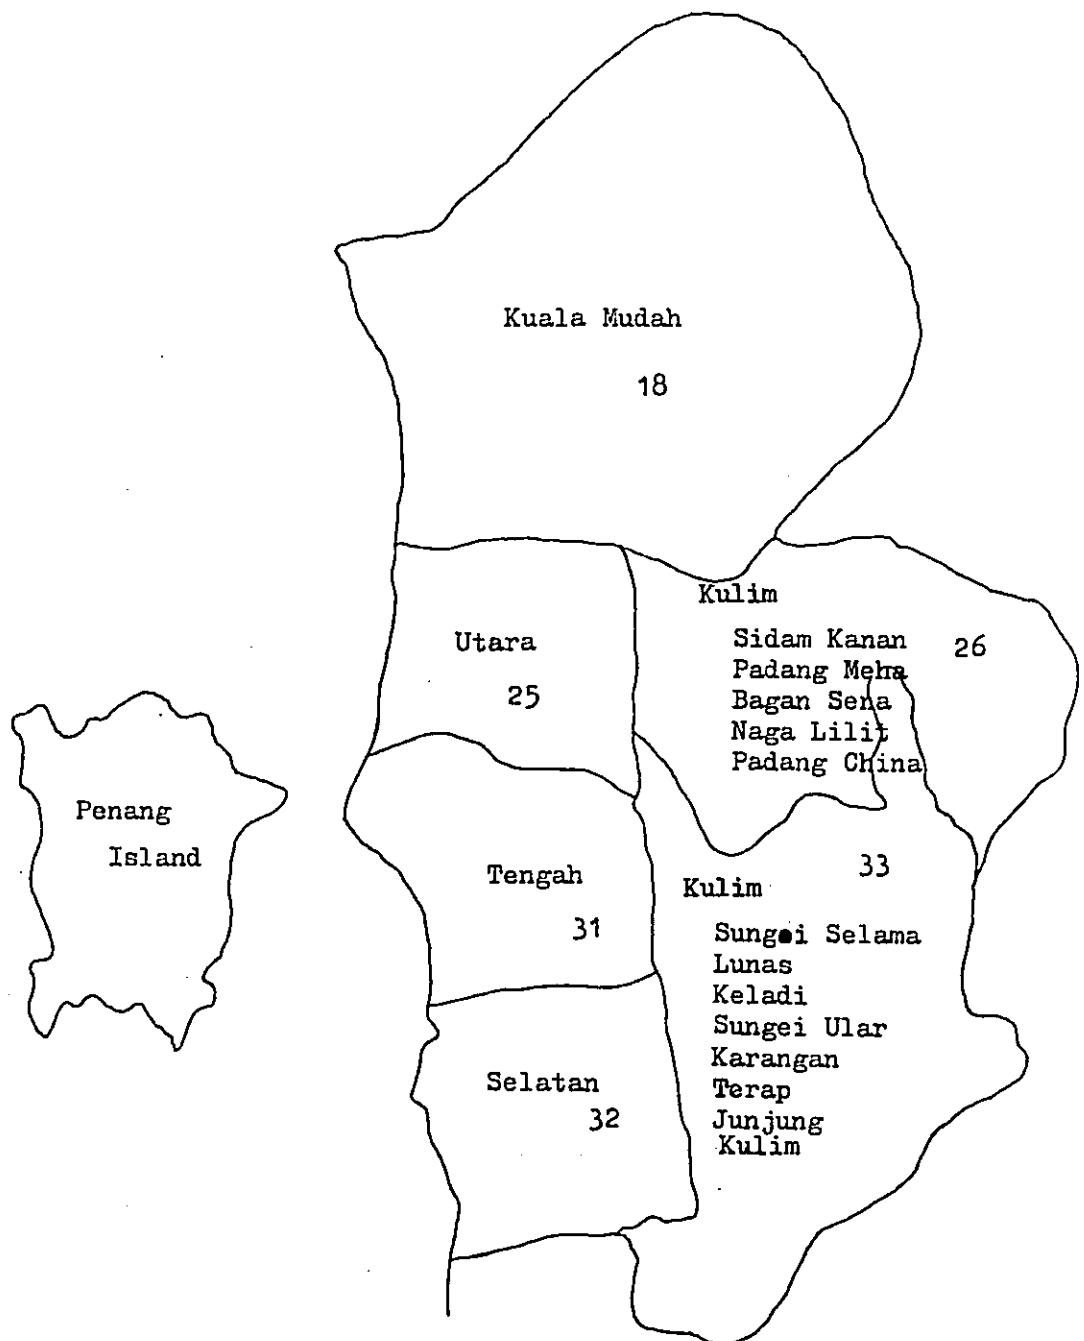

<u>CAR</u>	<u>CONDITION</u>	<u>TOTAL VEHICLE TRIPS</u>	
		<u>Improved F.R. 1</u>	<u>Unimproved F.R. 1</u>
1978	Current (Base-year)	N/A	61,500 (1.00)
1981	Forecast Opening Year	81,100 (1.32)	80,800 (1.31)
2001	Forecast Horizon Year	197,500 (3.21)	185,500 (3.02)
Per Cent Growth	1978 - 1981	31.9	31.4

N/A denotes Not Applicable.

2) Feasibility Study of the supporting road systems for the east-west highway.

This study area which covers a total of 12173 square miles, is made up of the following States; Kelantan, Kedah, Perak and Penang (excluding Penang Island). However, in this section, only the following areas as shown in Figure 4-19 will be described.

Figure 4-19 The Study Areas.

A. Pre-conditions

The following premises inputs are used to project the future traffic demand.

- i) population
- ii) employment
- iii) income

i) Population

The projected zonal population for the years: 1978, 1985 and 2000 for zones 18, 25, 26, 31, 32, 33 are as follows:-

Table 4-12: Population Projection (unit: 1000 person)

ZONE \ YEAR	1978	1985	2000
18	203.6	241.7	323.5
25	207.4	247.4	333.2
26	40.1	46.0	58.6
31	151.1	180.2	242.7
32	81.8	97.7	131.7
33	108.0	132.0	183.5

ii) Employment

The following table shows the projected employment by zone for 1978 and 2000, which are classified into primary, secondary and tertiary employment.

Table:4-13 Employment Projection

(unit: 1000 persons)

ZONE	1978				1990			
	Primary	Secondary	Tertiary	Total	Primary	Secondary	Tertiary	Total
18	32.2	6.1	20.7	59.0	35.1	9.4	32.3	76.8
25	18.3	13.5	26.7	58.5	15.6	19.5	42.9	77.9
26	7.1	-	-	7.1	7.2	-	-	7.2
31	10.4	8.7	17.6	36.7	9.8	12.2	26.8	48.8
32	9.9	3.1	7.2	20.2	10.2	5.4	11.3	26.9
33	19.7	3.8	14.1	37.6	22.1	6.8	23.2	52.0

(iii) Income

The projected average household income per month for the year 1978, 1985 and 2000 is tabulated in the below:-

Table: Income Projection

(unit: 1000 dollars)

Table 4-14 Average Household Income Per Month.

ZONE \ YEAR	1978	1985	2000
18	0.3	0.5	1.0
25	0.3	0.5	1.0
26	0.2	0.4	0.8
31	0.3	0.5	1.0
32	0.3	0.5	1.0
33	0.2	0.4	0.8

Methods of estimation

Travel Forecasting Procedure

Technique used are as follows:-

	Intra-zonal trips	Inter-zonal trips
Travel by motor-cycles cars and buses	Exponential decay and gravity model	Trip generation and gravity model
Commercial goods vehicles (include trucks, vans)	Percentage	Flow patterns from development plans

Intra-zonal trips refer to trips made between towns and agricultural hinterland.

Inter-zonal trips include work and recreational trips.

Person Trip Demand Models

This section deals with the estimation of traffic volumes generated by the

- I) Passenger vehicle Travel Forecast
- II) Commercial vehicle Travel Forecast

## I. Passenger Vehicle Use and Travel

### A) Estimation of Vehicle Use and Travel

The following models were used for the estimation of vehicle use and travel:

#### i) Trip generation model

It is based on a category analysis of the population of a number of cities. They are:

- a) low density residential
- b) medium density residential
- c) high density residential
- d) trip attraction

These models are based on the assumption that the community is dependent on the population, its distribution and vehicle ownership of their community. The models were developed from data collected through comprehensive surveys. Let us now examine each of them.

#### a) Vehicle ownership model

This model was developed from a regression analysis of household income and vehicle ownership. It was used to estimate the propensity to own a vehicle and related to the number of vehicles available in a household. The model was developed from a set of data on household income and vehicle ownership. The model is based on the following assumptions:

- no vehicle in household
- motor-cycles in household
- one car in household and
- many cars in household

A series of regression models were developed for the study in the different vehicle types classified according to the level of urbanisation.

#### b) Income distribution model

The income distribution model was used to estimate the distribution of individual households by income. It was based on the following assumptions: household income distribution:

#### c) Trip production model

These models were used to estimate the trip production

rates which are related to income levels and vehicle ownership for each of the zones in the study area. (refer to Table 4.3.2.)

d) Trip attraction model

This model relates the attractiveness of the zones to its population and employment opportunity.

ii) Trip distribution model

It predicts the origins and destinations of general trips. A standard gravity model is used. The model has the mathematical form:-

$$V_{ij} = C \cdot P_i \cdot A_j \cdot F_{Tij} \cdot K_{ij}$$

where  $V_{ij}$  = volume of trips originating in zone i and attracted to zone j.

$P_i$  = trips produced at zone i

$A_j$  = trips attracted to zone j

$T_{ij}$  = travel time between i and j

$F$  = friction factor which is a function of time

$K_{ij}$  = adjustment factor for special conditions such as socio-economic differences, large "perceived" barriers to travel (such as the Penang Island Ferry) etc.

$$C = \text{normalization constant} \frac{1}{\sum_{i,j} P_i \cdot A_j \cdot F_{Tij} \cdot K_{ij}}$$

iii) Trip Assignment Model

The "all or nothing" model was used for the traffic assignment.

iv) Modal Split

The modal split procedure was based on the projected vehicle ownership rates, household categories, population density and urban structures.

B) Estimation of Intra Zonal Person Travel demand

Estimation is based on

- i) a gravity model estimate of the total number of intra-zonal person trips for each zone and bench-mark year
- ii) an allocation of intra-zonal trips to individual links

and an exponential decay function to obtain estimate of average link volumes.

#### Conversion of Person Trips to Passenger Vehicle Trips

The modal split which is based on the projected vehicle ownership rates, household categories, population density and urban structure was used to convert person trips to passenger vehicle trips.

#### II. Commercial Vehicle Travel Estimation

The estimation methods here are based on development plans and projections of freight inflow in to the study area.

The procedures involve the following:-

- Determination of freight flow resulting from export of forest and farm-based products.
- determine the routes to the destinations.
- freight flow was allocated between light vans and trucks based on traffic data in the study area.
- freight inflow to districts was projected in 2 different ways. They are determined on the basis of
  - 1) the proportion of flow of rural produce originating in each district and
  - 2) the urban/rural population distribution
- constant vehicles mixing was assumed throughout the study period.
- freight flow was converted to commercial vehicle trips on the basis of
  - i) commodity tonnage
  - ii) average loading of different commercial vehicle types
  - iii) those goods which have been determined on the basis of proportion of flow of rural produce originating in each district.

The data obtained from HPPTU were used as data base for the forecasting procedures outlined above. In this way, agricultural commodities and miscellaneous freight were estimated.

**TABLE 4-15 PROJECTED TRAFFIC VOLUMES ON SEGMENT W9**

<b>Year</b>	<b>Motor-Cycle</b>	<b>Car</b>	<b>Van</b>	<b>Lorry</b>	<b>Bus</b>	<b>Total</b>
<b><u>Base Case</u></b>

2000	5,065	8,826	230	700	579	15,400

Traffic volume and number of vehicles.

We have no past-trend data concerning to the unit trip production. Instead of that, the data of traffic volume and number of vehicles can be obtained, therefore the relation between the both of them will be mentioned in this chapter.

A. Number of vehicles.

The past-trend data about the number of vehicles are shown as follows:

Table 4-16 The Trend Of The Number Of Vehicles

II	1965	1970	1975	1979	Average annual percent growth		
					1965 - 1970	1970 - 1975	1975 - 1979
Cars	20975	28326	45578	65352	6.2	10.0	9.4

		1965	1970	1975	1979
Number Of Vehicles	Vehicle	171.7	100	160	226
	Motorcycle	57.2	100	188	264
	Total	63.3	100	176	248
Traffic volume by J.K.R.			100	154	245
F e r r y	Vehicle	76.2	100	168	(270)
	Motorcycle	43.3	100	186	(304)
	Total	59.4	100	177	(287)

Fig: 4-20 The trend of the index number

These figures show that the traffic volume are roughly following the number of vehicles excepting that the ferry traffic in 1975 - 1978 are increasing more than the increase of number of vehicles.

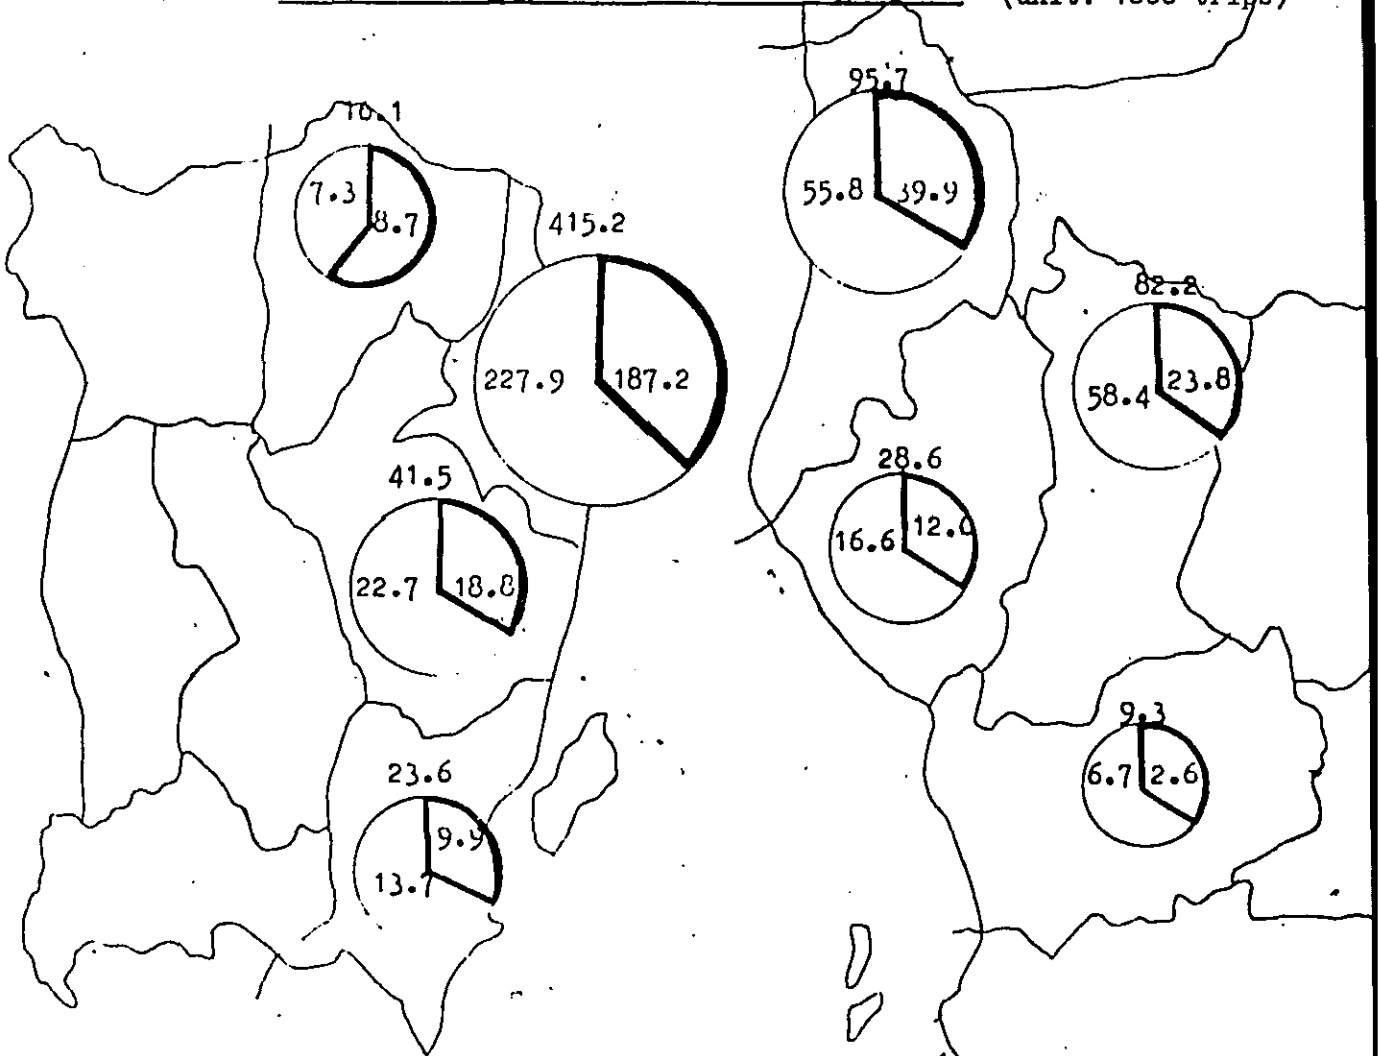

It can be said that the traffic volume up to this time increase in proportion to the number of vehicles or slightly exceed the increase of those. Therefore, it is estimated that the unit trip production is constant by year or may be slightly increased.

On the basis of these consideration, the unit trip production in future will be made use for the present value which were obtained though our traffic survey.

Trip generation and attraction

The total number of trips generated from the internal area is 303,000 trips per day for vehicles and 409,000 trips per day for motorcycles. The number of trips generated in the large zones are shown in the following figure and it is remarkable that the trips generated is made up of about 62% vehicles and 56% motorcycles.

Fig: 4-21 Number of trip generated in the large zones (unit: 1000 trips)

	P.I	P.W
VEHICLES	214.6 (74.2%)	78.2 (25.8%)
MOTORCYCLES	771.7 (66.4%)	137.5 (33.6%)

The following figure shows the comparison between the composition of trip generation and the population in the large zone.

Fig: 4-22 Comparison between the composition of trip generation and the population in the large zone.

	trip generation of vehicles	population	trip generation of motorcycles
zone 1	61.8 %	P.I. 74.2 %	P. I. 55.7 % 66.4 %
		47.1 %	
		3.7 %	
		10.2 %	1.8 %
			5.6 %
zone 2	2.9 %		3.3 %
zone 3	6.2 %		
zone 4	3.3 %		
		15.4 %	13.6 %
zone 5	13.1 %	P.H. 25.3 %	P.H. 4.1 % 33.6 %
		6.8 %	
zone 6	3.9 %		14.3 %
		9.3 %	
zone 7	7.9 %		
zone 8	0.7 %		3.6 %

The composition of trip generation of motorcycles is almost the same as the population. This means that the trip generation of motorcycle is almost proportional to the population, whereas the trip generation of vehicles is not proportional to the population. The reason for this is that the trip generation of vehicles is related to the degree of urbanization in the area.

The classification of zones

Each traffic zone has various characteristics. For instance, the commercial, the residential, the industrial and the business area come under one classification; that of land-use. High density, medium density and low density is another classification which makes use of population density.

In this section, another classification was attempted by using the results of traffic surveys. This classification is called the zone classification by traffic characteristics.

(1) Method of classification

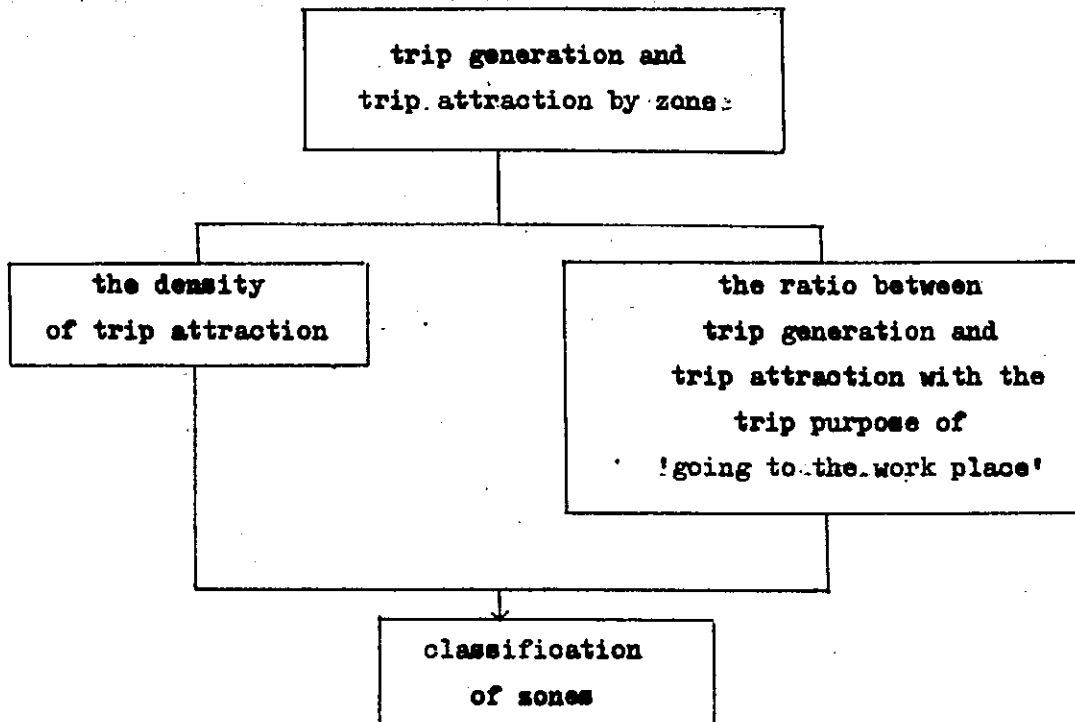

Through traffic surveys, the O-D table by vehicle type and trip purpose was obtained. The classification is done by using that O-D table. A lot of information which are related to the characteristics of the zones can be obtained from the O-D table, as for examples, the volume of trip generated and trip attracted and the composition of trip purpose which is the result of generated and attracted will be an indicator of the intensity of trip generation and attraction.

The urbanized zone has many 'attractive' facilities and they constitute the attractive forces of that zone. The more attractive the zone grow, the greater the number of trips attracted there. Therefore, the density of trip attraction is chosen as one of the indicators for classifying the zones.

Besides this, trip purpose is also useful for the classifying procedure. If the zone is a residential area, many trips with the trip purpose of 'going to the work place' will be generated from this zone and if the zone is a business area, many trips with the trip purpose of 'going to the work place' or 'business engagement' will be attracted into this zone. Therefore, the ratio of trip generation to trip attraction having the trip purpose of 'going to the work place' is used for the classification of the zones.

The classification is done according to the following flow chart.

Figure 4-27 Flow chart of zone classification.

(2) The procedure of classification

Following the above-mentioned method, the graph is plotted to classify the 57 zones in the study.

The Y-axis of the graph represents the density of trip attraction by area size. The density of trip attraction is used here for zone classification because it shows us how 'attractive' that particular zone is.

The X-axis of the graph represents ratio of trip attraction to trip generation with the trip purpose of 'going to work'. If this ratio is high, it implies that a particular zone is a business area since many trips with the trip purpose of 'going to work' will be attracted to that zone. The point where the ratio of trip attraction and generation is equal to 1 is chosen as the line of demarcation. Thus, those zones which lie to the right of the line where  $x = 1$  is classified as business areas while those that lie on the left is classified as residential areas.

This classification can be seen in the following graph and the results of this classification is shown in Fig. 4 - 28

Fig: 4-28

CLASSIFICATION OF THE 57 ZONES IN THE STUDY ACCORDING TO THEIR DENSITY OF TRIP ATTRACTION AND THE RATIO OF TRIP ATTRACTION AND TRIP GENERATION FOR THE TRIP PURPOSE OF "GOING TO WORK PLACE."

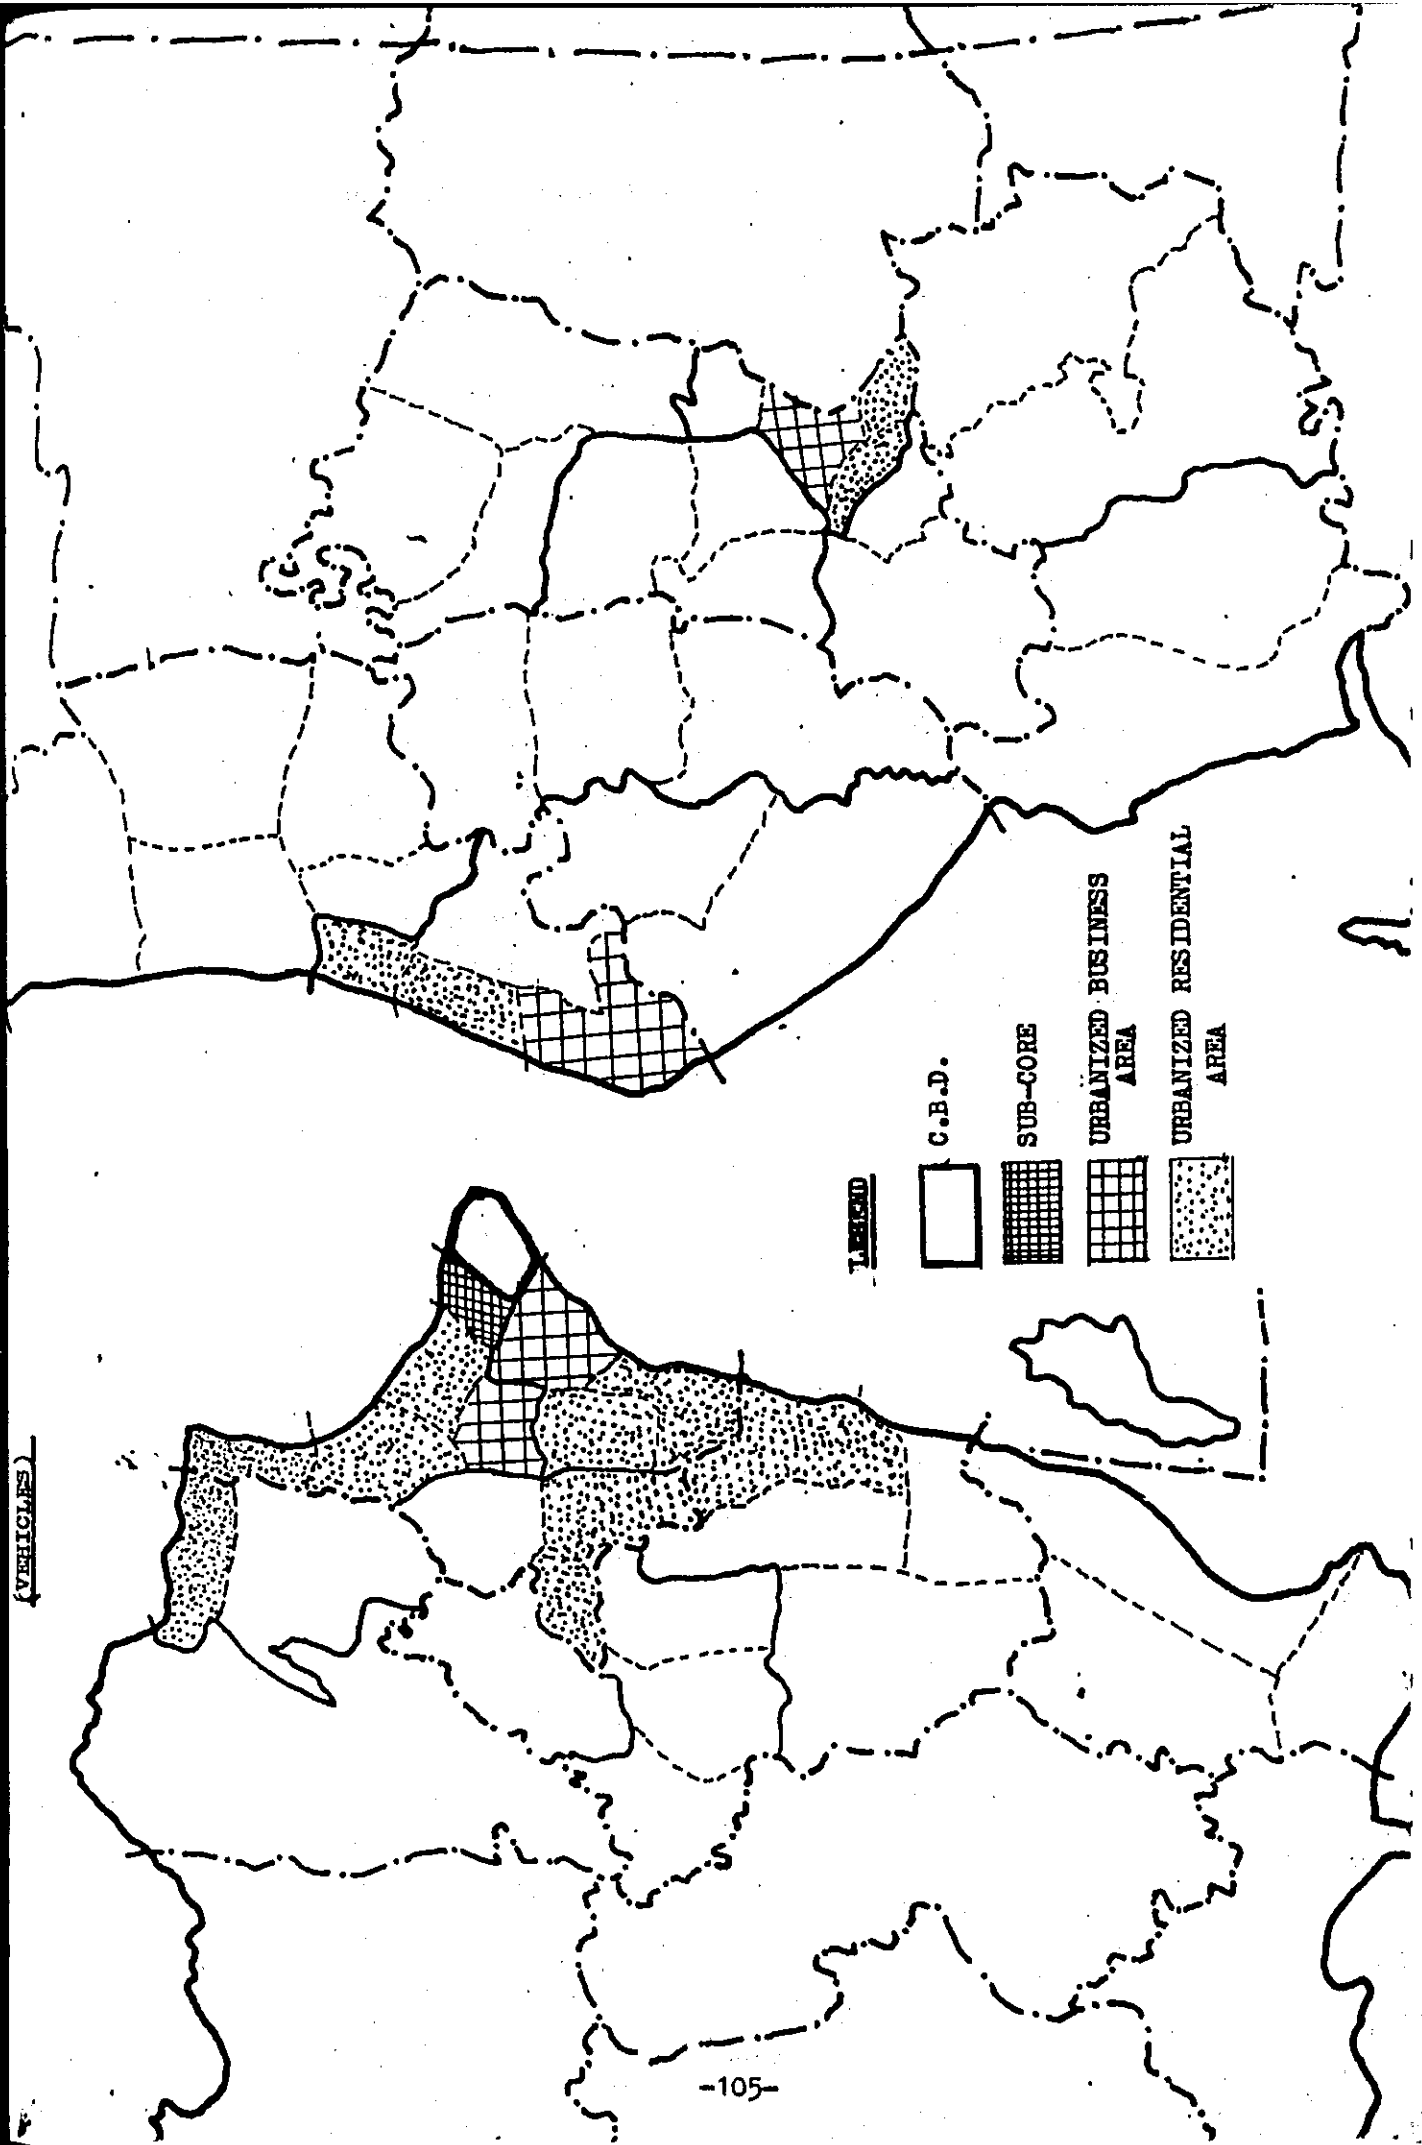

NUMBER OF TRIP ATTRACTION

AREA SIZE

NUMBER OF TRIP ATTRACTION (GOING TO WORK PLACE);  
NUMBER OF TRIP GENERATION (GOING TO WORK PLACE)..

(VEHICLES)

The results show that this classification is appropriate. From this, it can be concluded that the volume of trip generated and trip attracted by the zones which have been obtained through traffic surveys is accurate.

4-3-3

Analysis of trip generation and attraction

Usually, the regression method and the basic unit method are used for the analysis of trip generation and attraction. In this study both these methods will be examined. After which, the suitable method and suitable explanatory variables will be chosen.

(1) The basic unit method

The basic unit of trip generation is obtained by means of dividing the trip generation by the population of each zone. The results are shown in the following figure.

Fig: 4-30 The basic unit of trip generation (vehicles).

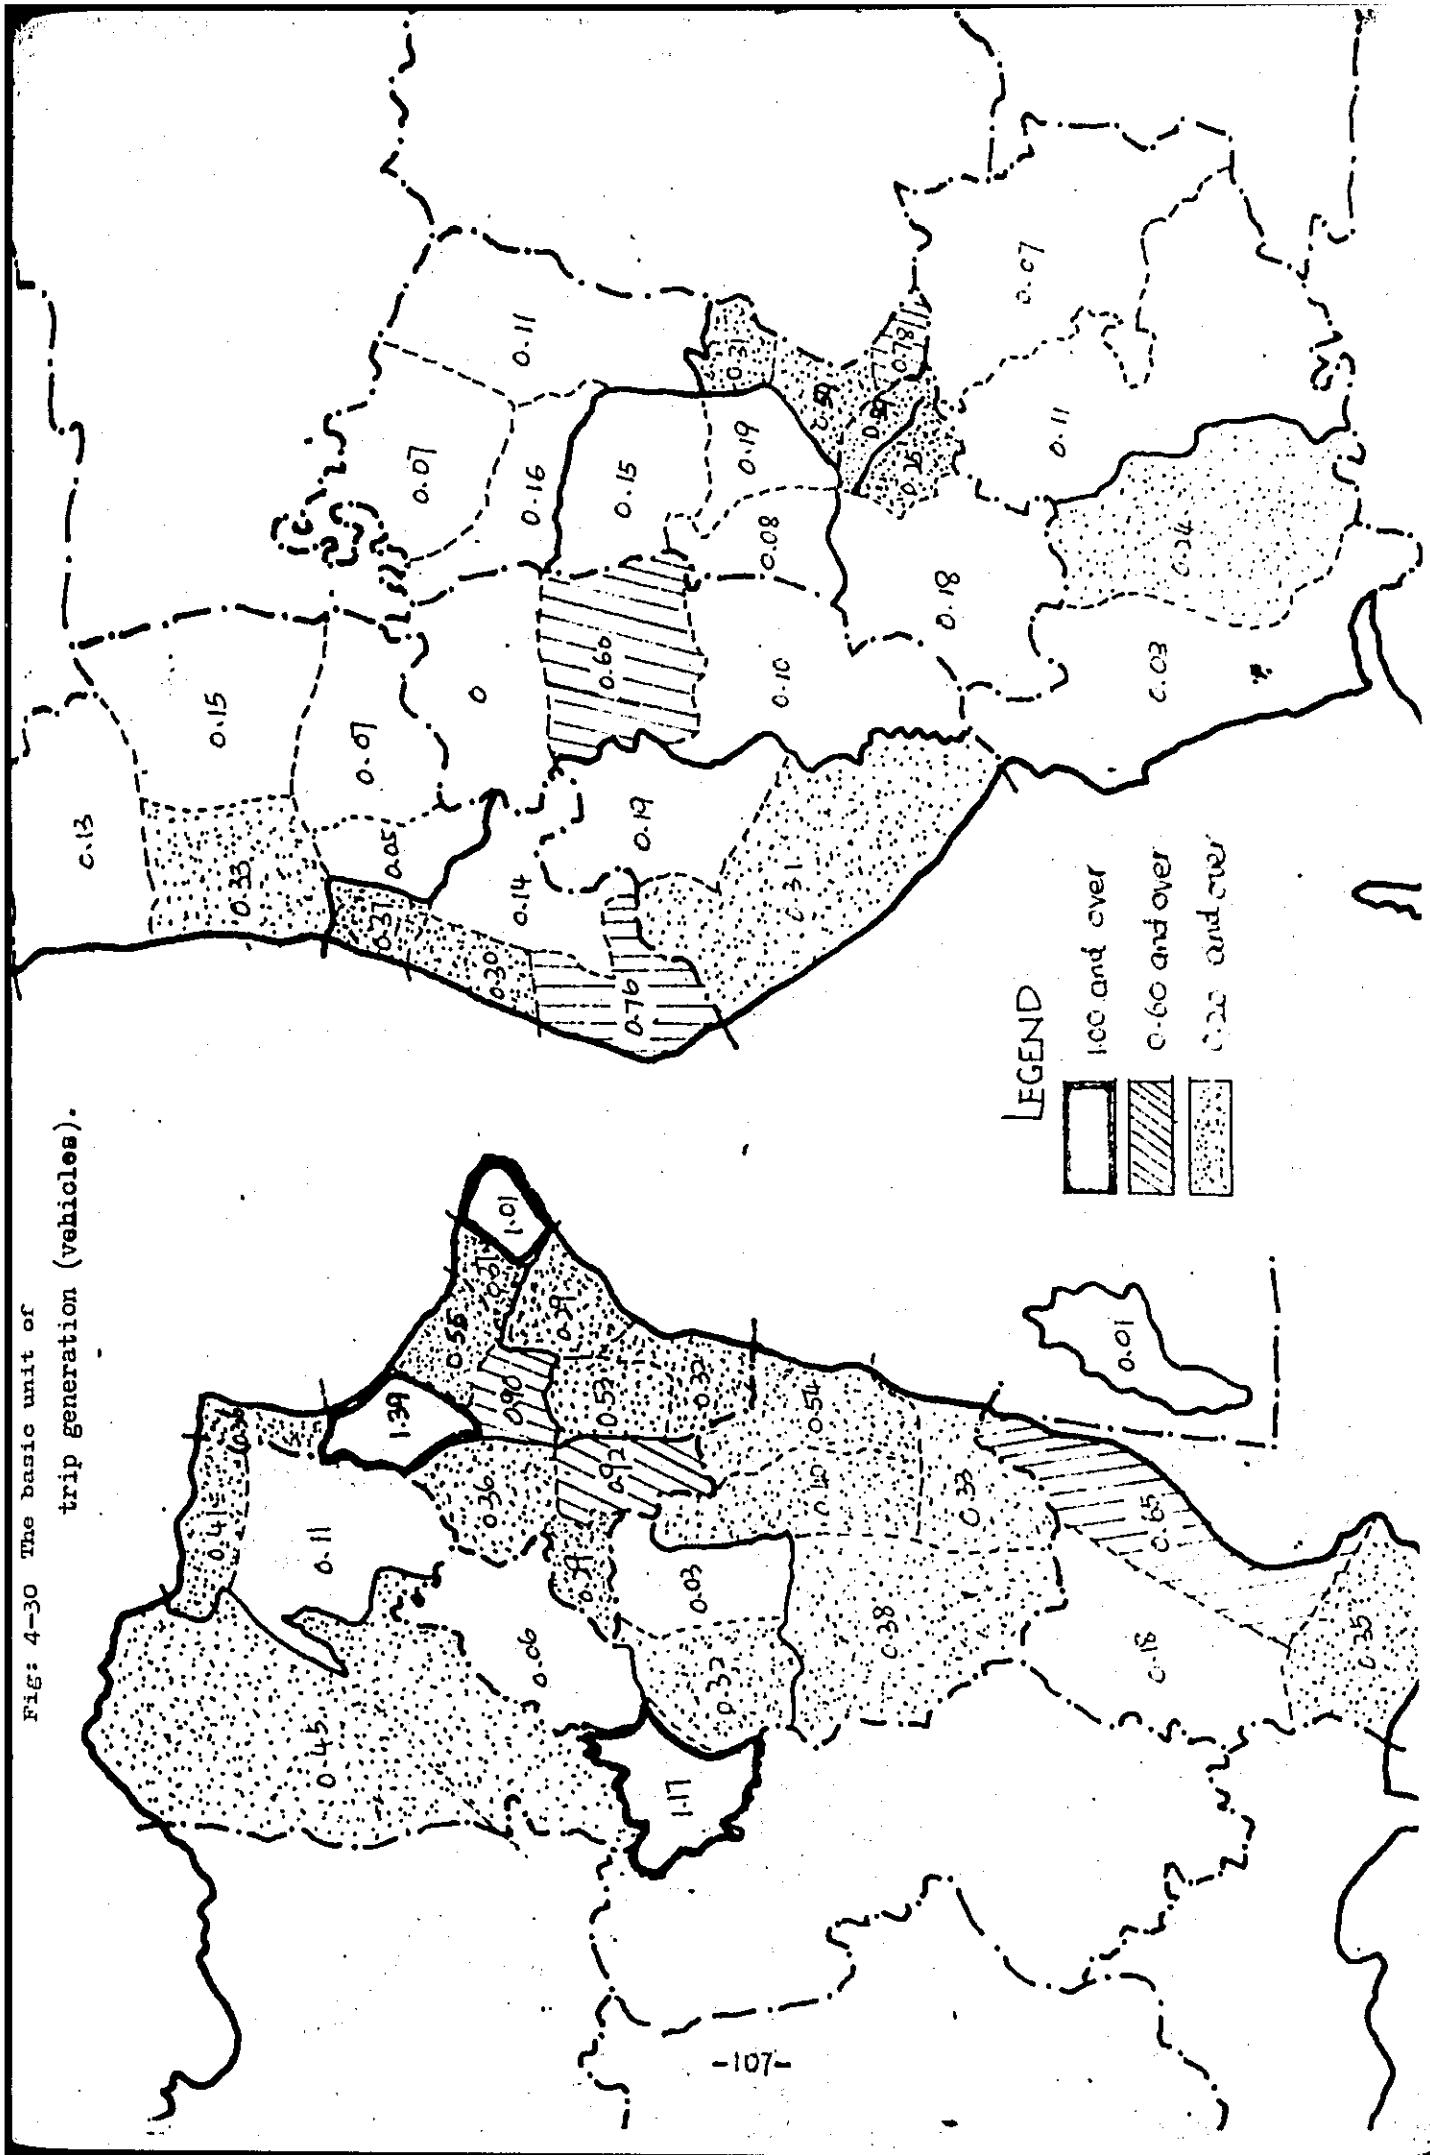

Fig: 4-31 The basic unit of trip generation (motorcycles).

(unit: trip end/person)

The basic unit of trip generation by zone is not constant, but it exhibits a certain trend, that is, the zones in the urban areas have a high basic unit while the zones in the rural areas have a low basic unit although there are some exceptions to this trend. These results show that the trip generation of a particular zone is dependent upon the character of that zone, and the character of that zone cannot be explained by only one factor. Therefore, it is advisable to use some explanatory factors in order to complete the traffic model for trip generation.

(2) The regression method

In the regression method, the least square method is used to obtain the regression equation. The regression equation consists of the explained variable and the explanatory variables. In this case, it is natural that the explained variable is the trip generation by zone while the explanatory variables make use of the following factor, i.e. the area by land-use, the floor size by purpose of buildings, the population and the employed population by industry etc.

For the purpose of drawing up the traffic model of trip generation, only some factors need be chosen. However, the following criteria must be observed:-

- (1) The explanatory variables for the present and also for the estimated target year must be obtained.
- (2) It has some causal relationship. The explanatory variables must not be chosen only from the degree of co-efficient of correlation.

Taking into consideration the above matter, some indices of population are chosen as the explanatory variables in this study as shown in the following table:-

Table 4-22 The explanatory variables

		Trip generation		Trip attraction	
		Resident population	Employees	Resident population	Employees
Car	Trip to work	0			0
	Business trip		0		0
	Private trip	0	0		0
	Trip home		0	0	
Lorry			0		0
Taxi		0	0	0	0
Bus		0	0	0	0
Motorcycle		0	0	0	0

The traffic model of trip generation and trip attraction which is drawn up by the least square method is as follows:-

Table 4-73 Trip model of trip generation and trip attraction

	Trip generation	Trip attraction
Car	Trip to work $y = 0.0916 x_p + 0.844$ (R = 0.774)	$y = 0.405 x_E - 404$ (R = 0.884)
	Business trip $y = 0.172 x_E - 80.7$ (R = 0.894)	$y = 0.172 x_E - 80.7$ (R = 0.894)
	Private trip $y = 0.0560 x_p + 0.0829 x_E - 101$ (R = 0.828)	$y = 0.250 x_E - 38.2$ (R = 0.811)
	Trip home $y = 0.440 x_E - 247$ (R = 0.864)	$y = 0.101 x_p + 177$ (R = 0.711)
Lorry	$y = 0.116 x_E + 92.4$ (R = 0.851)	
Taxi	$y = 0.000941 x_p + 0.0186 x_E - 12.2$ (R = 0.770)	
Bus	$y = 0.0242 x_p + 0.00728 x_E - 44.5$ (R = 0.736)	
Motorcycle	$y = 0.340 x_p + 1.01 x_E - 1514.5$ (R = 0.945)	

y = trip generation or trip attraction by zone

x<sub>p</sub> = population by zone

x<sub>E</sub> = employed population by zone

R = co-efficient of correlation

(3)

### Conclusion

For the model of trip generation and attraction, two methods were examined. The co-efficient of correlation of both methods show that the regression method is more suitable than the basic unit method for explaining the situation of trip generation and attraction. Therefore, the regression method was chosen for the generation/attraction model. However, the question is whether these models can explain the trip generation and attraction of each zone as each have their unique characteristics. Therefore, these model are to be used for the calculation of increasing trip generation/attraction from the year 1979 to 1985 or 2000. This is as follows :-

example :

By using this method, present zonal characteristics will be considered.

Trip Generation (1979)

4-4 Analysis of Trip Distribution.

The trip distribution in this study area is as follows :-

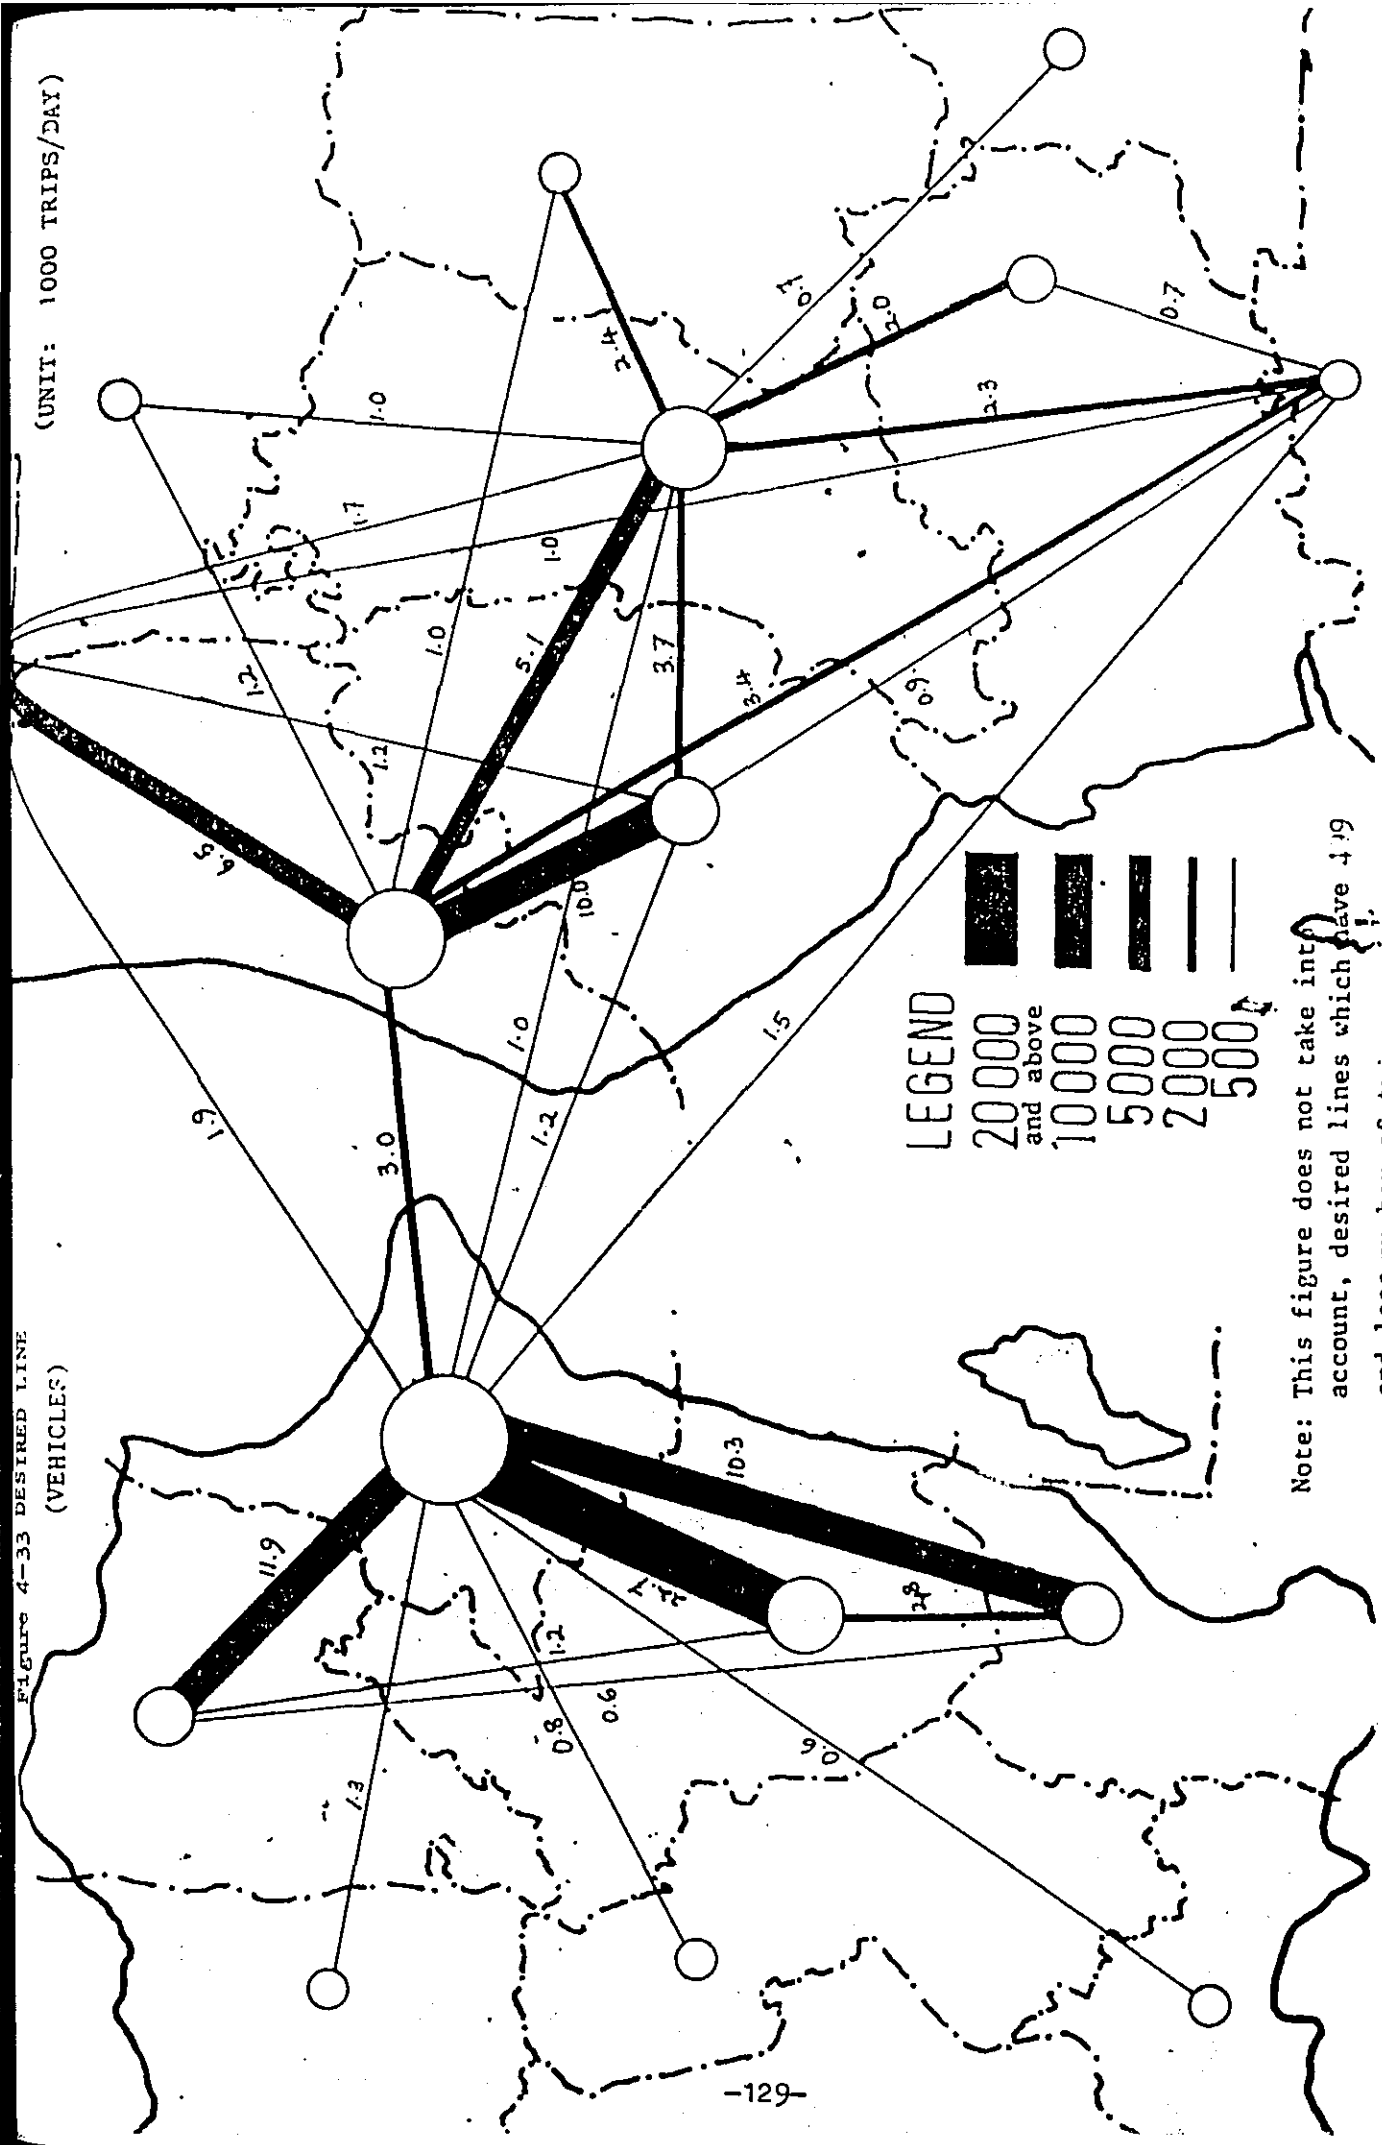

Figure 4-32 Trip distribution.

The desired line can be seen in the following fig. It shows that in Penang Island, radial traffic which concentrates into large zone 1 (George Town City) is conspicuous and contribute to a large part of the traffic in Penang Island, while in Province Wellesley, traffic which go to and return from zone 5 (Butterworth), zone 6 (Prai area) and zone 7 (Bukit Mertajam) form a triangular traffic flow.

The territory of traffic flow

From the O - D table by trip purpose, it is possible to know the territory of traffic flow formed.

The figures no. 4-34 to show this are drawn by the following method.

Figure 4-35 Method for classification of the territory of traffic flow.

The following figures number 4-35, 4-36, 4-37, 4-38, 4-39 and 4-40 are drawn by using the following O-D table.

O-D table

Car	Trip to work
	Business trip
	Private trip
Motor-cycle	Trip to work
	Business trip
	Private trip

Looking at figure 4-35 . . . we find that there are three territories in this study area and the territory with zone 111 as its centre the widest area with zone 511 and then zone 732 coming second and third respectively.

In the territory map of business trips of cars, the territories of zone 511 and 732 are joined.

This suggests that there is a possibility the future traffic situation will be like this.

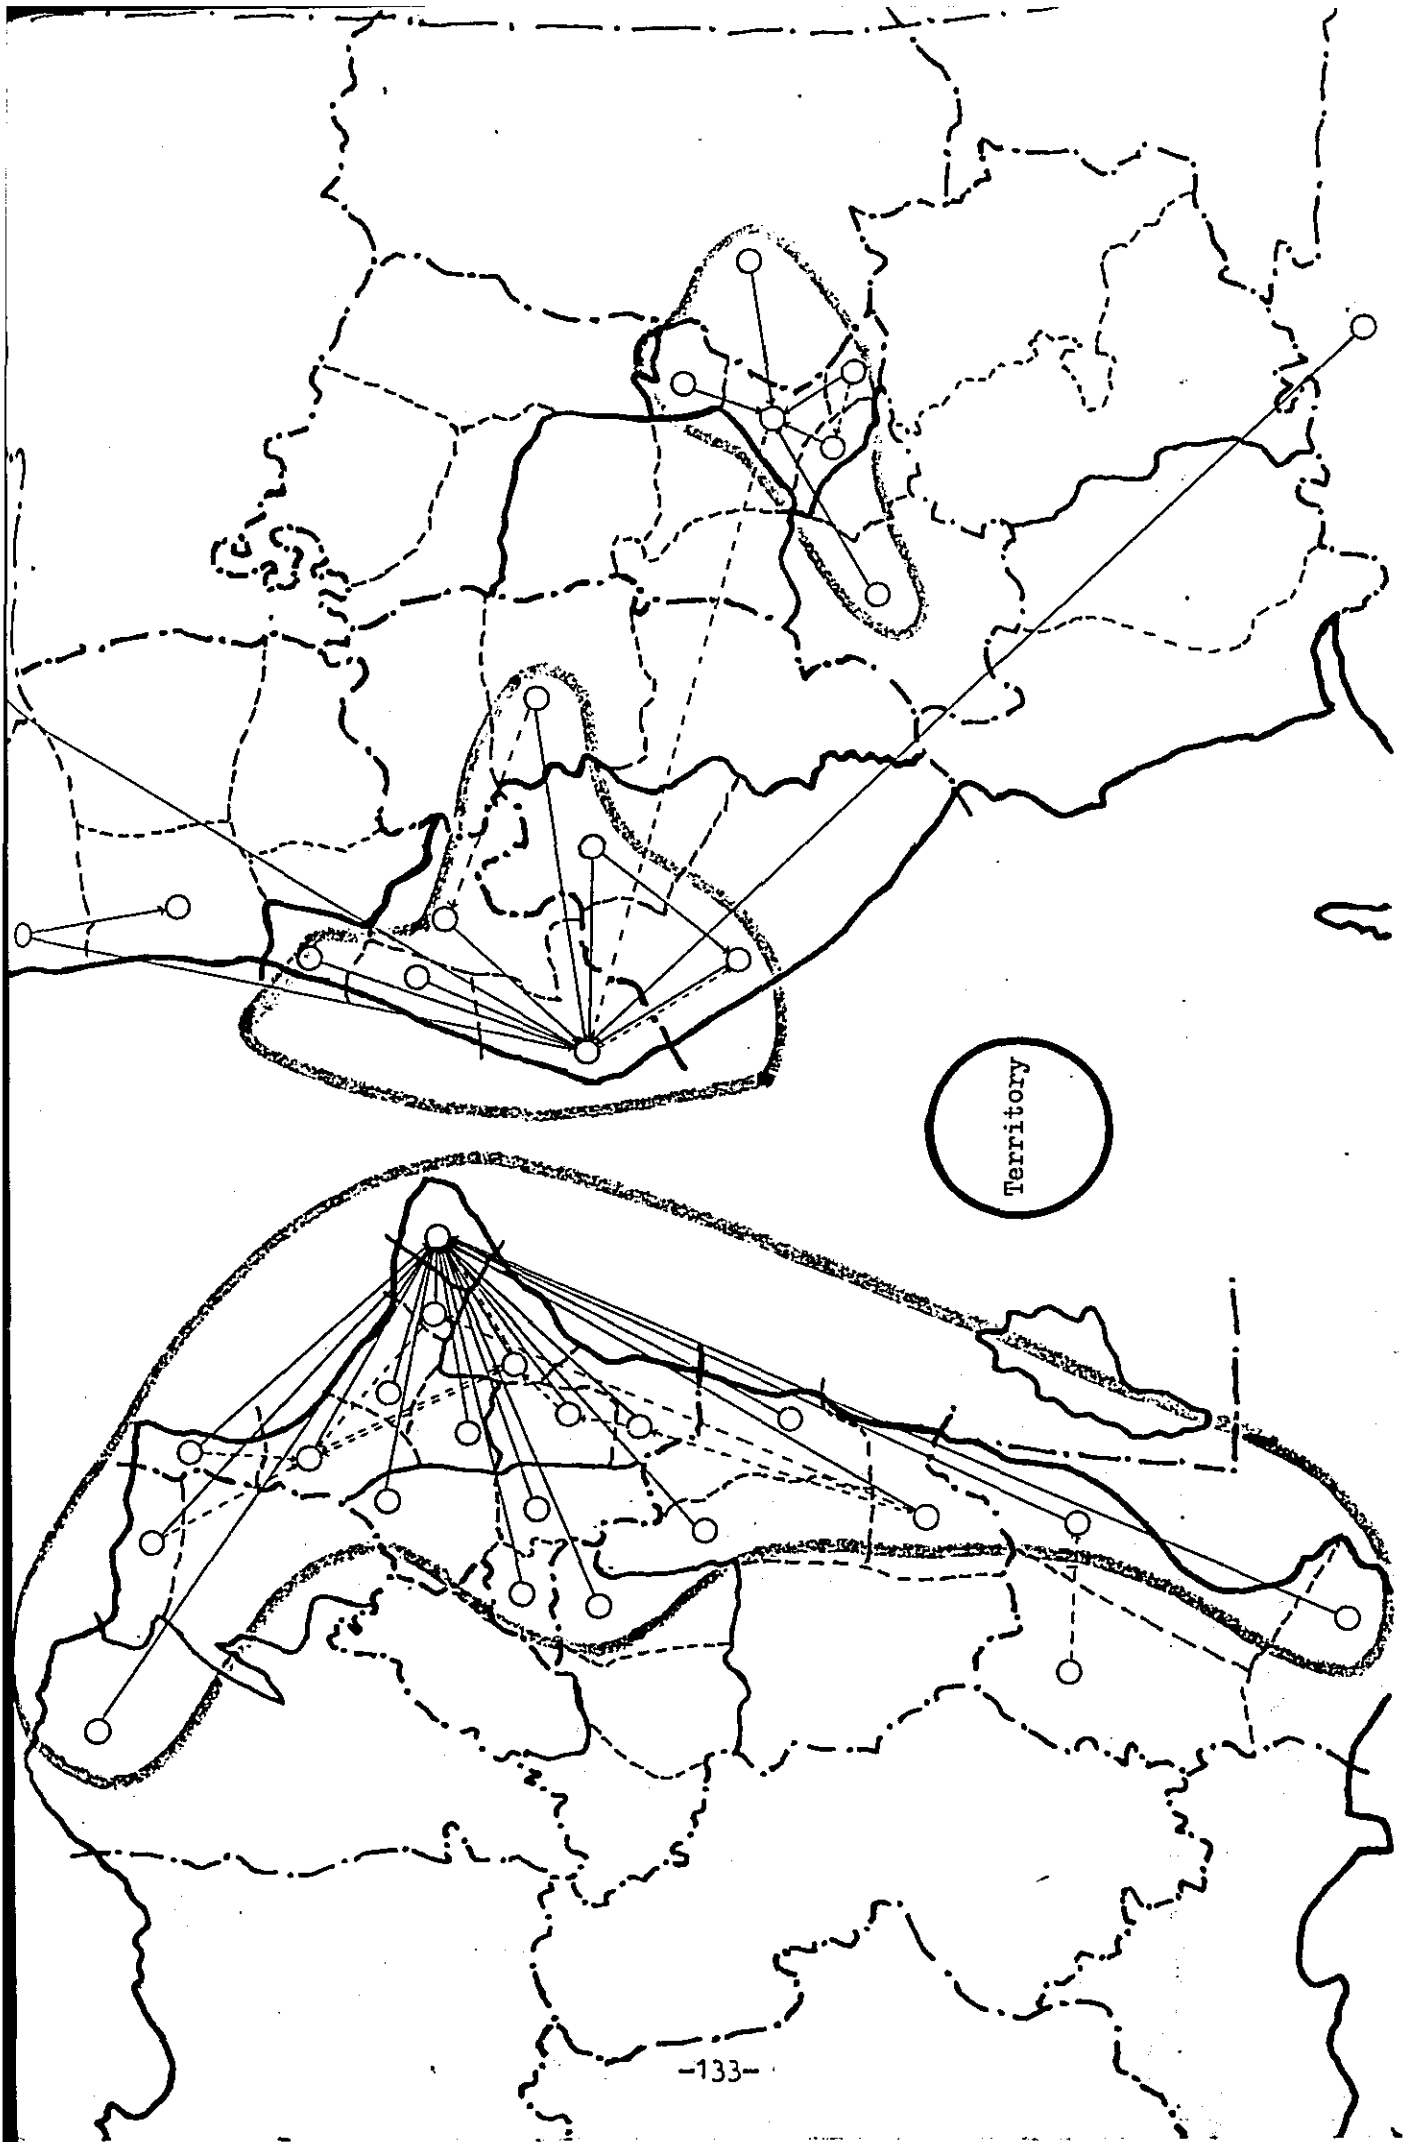

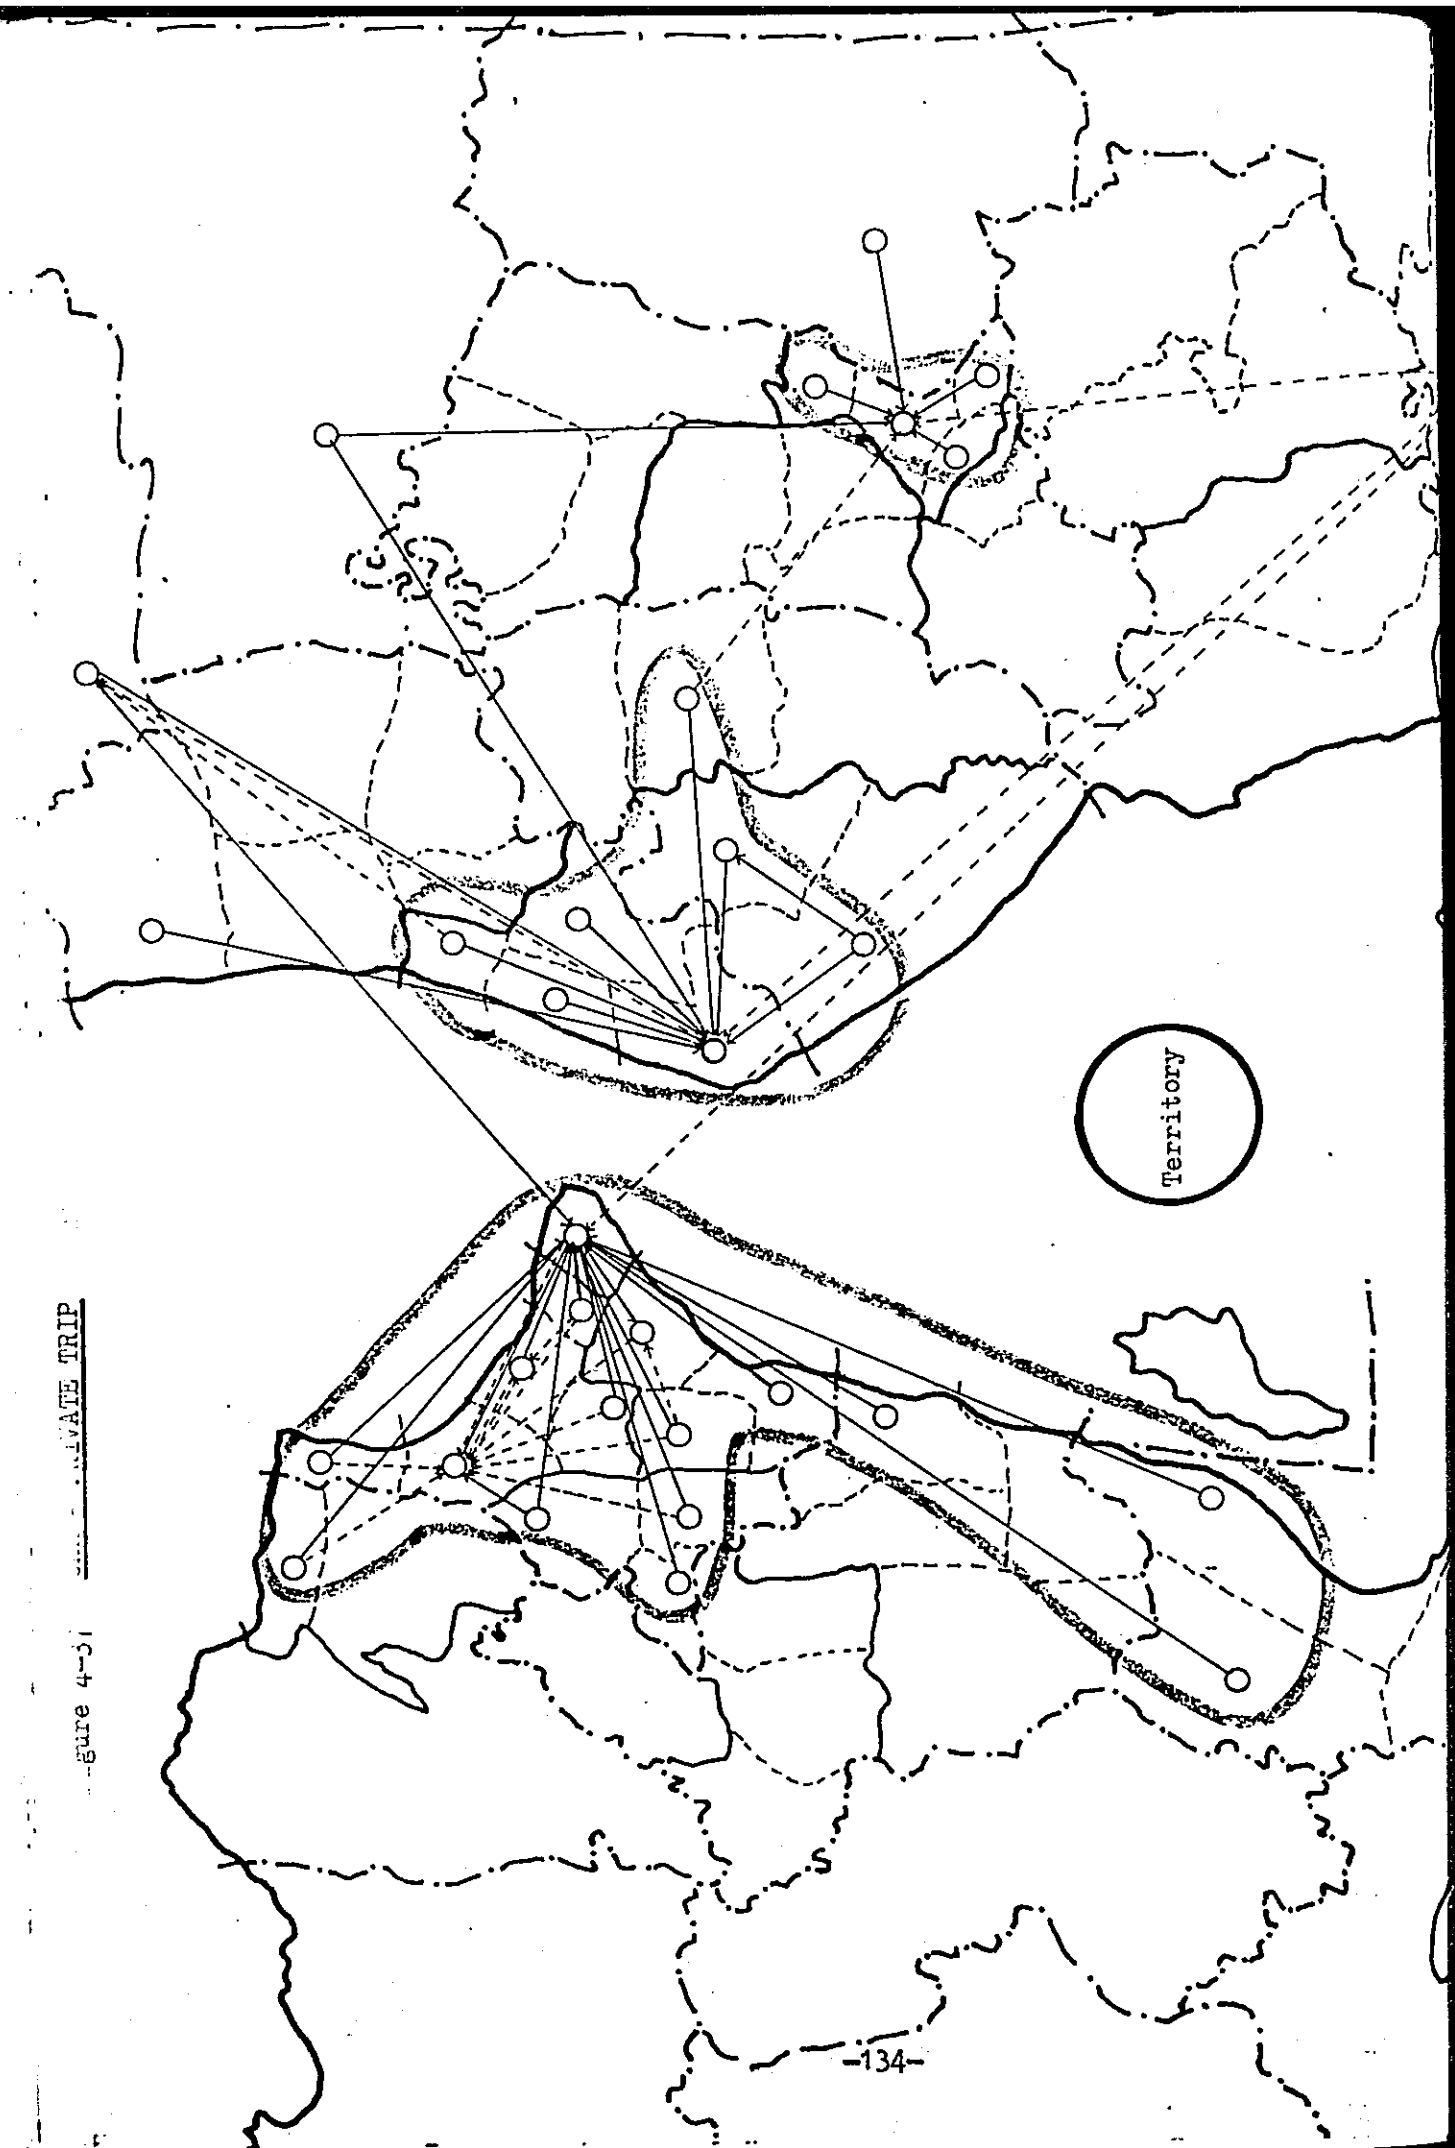

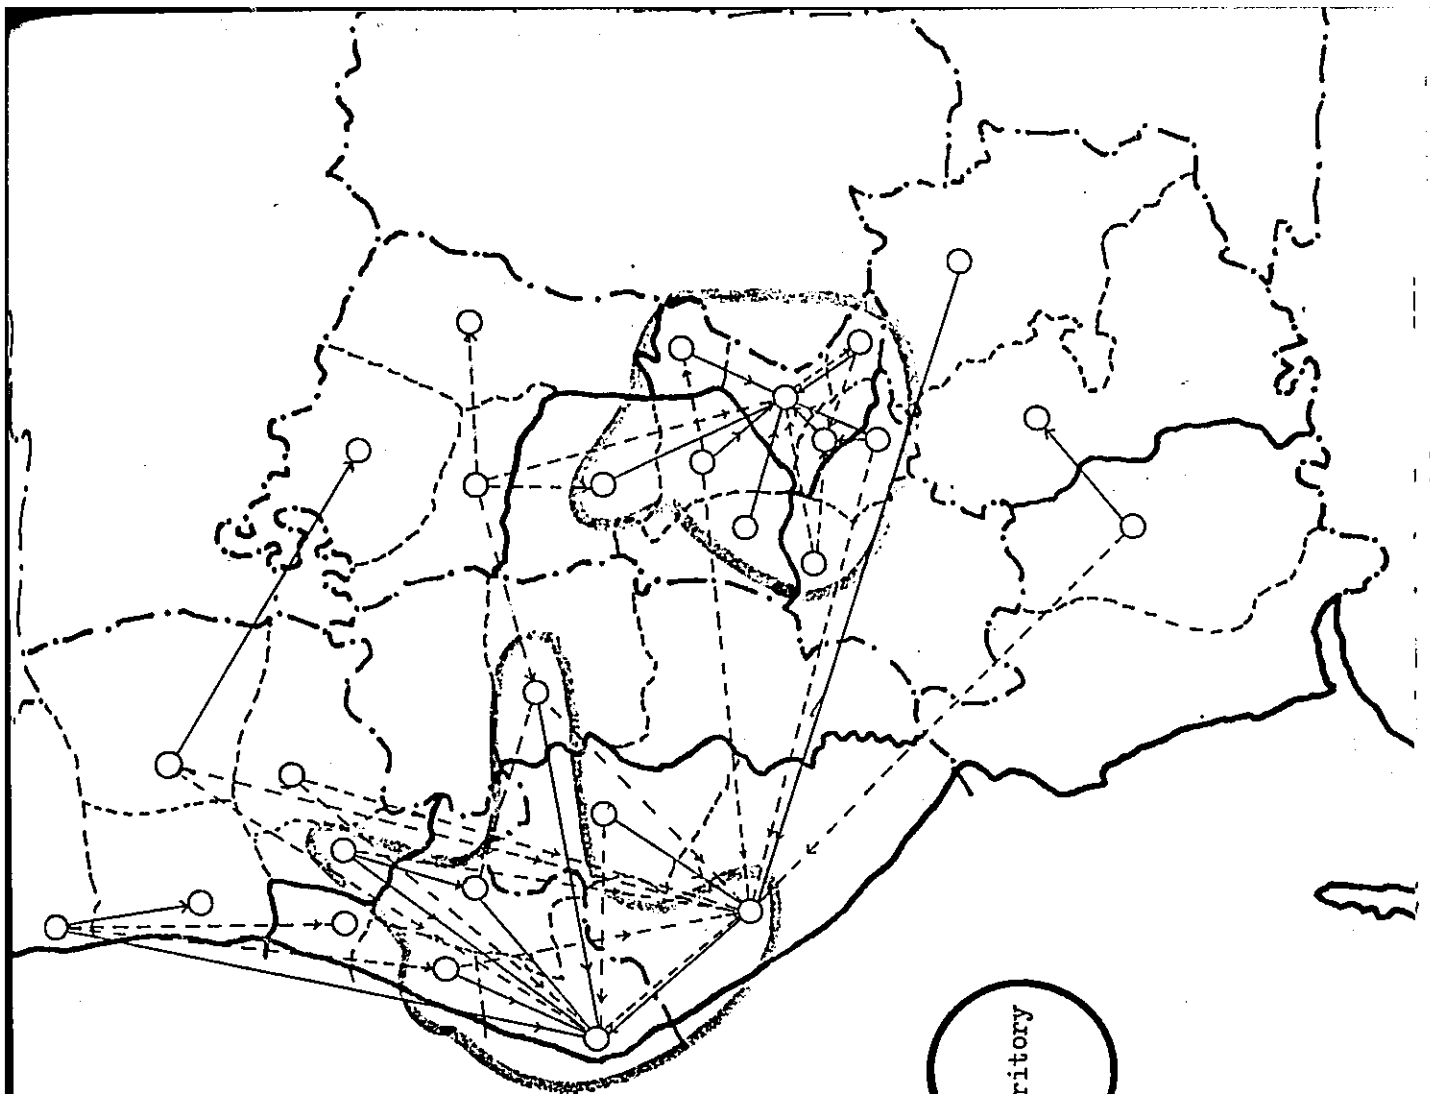

Figure 4-51 PRIVATE TRIP

Territory

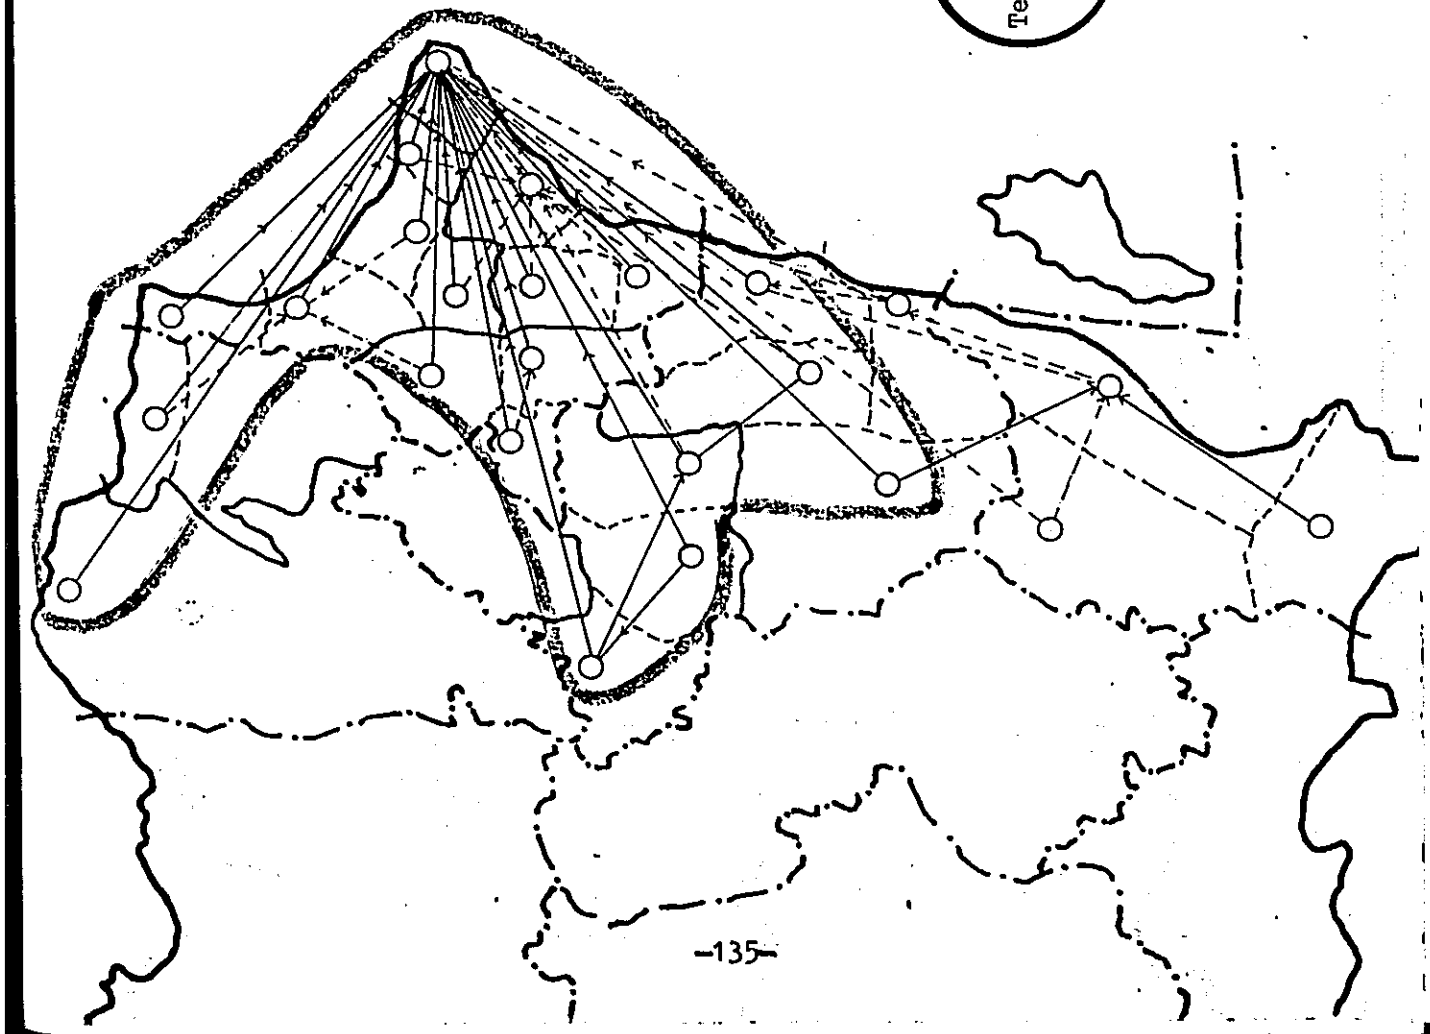

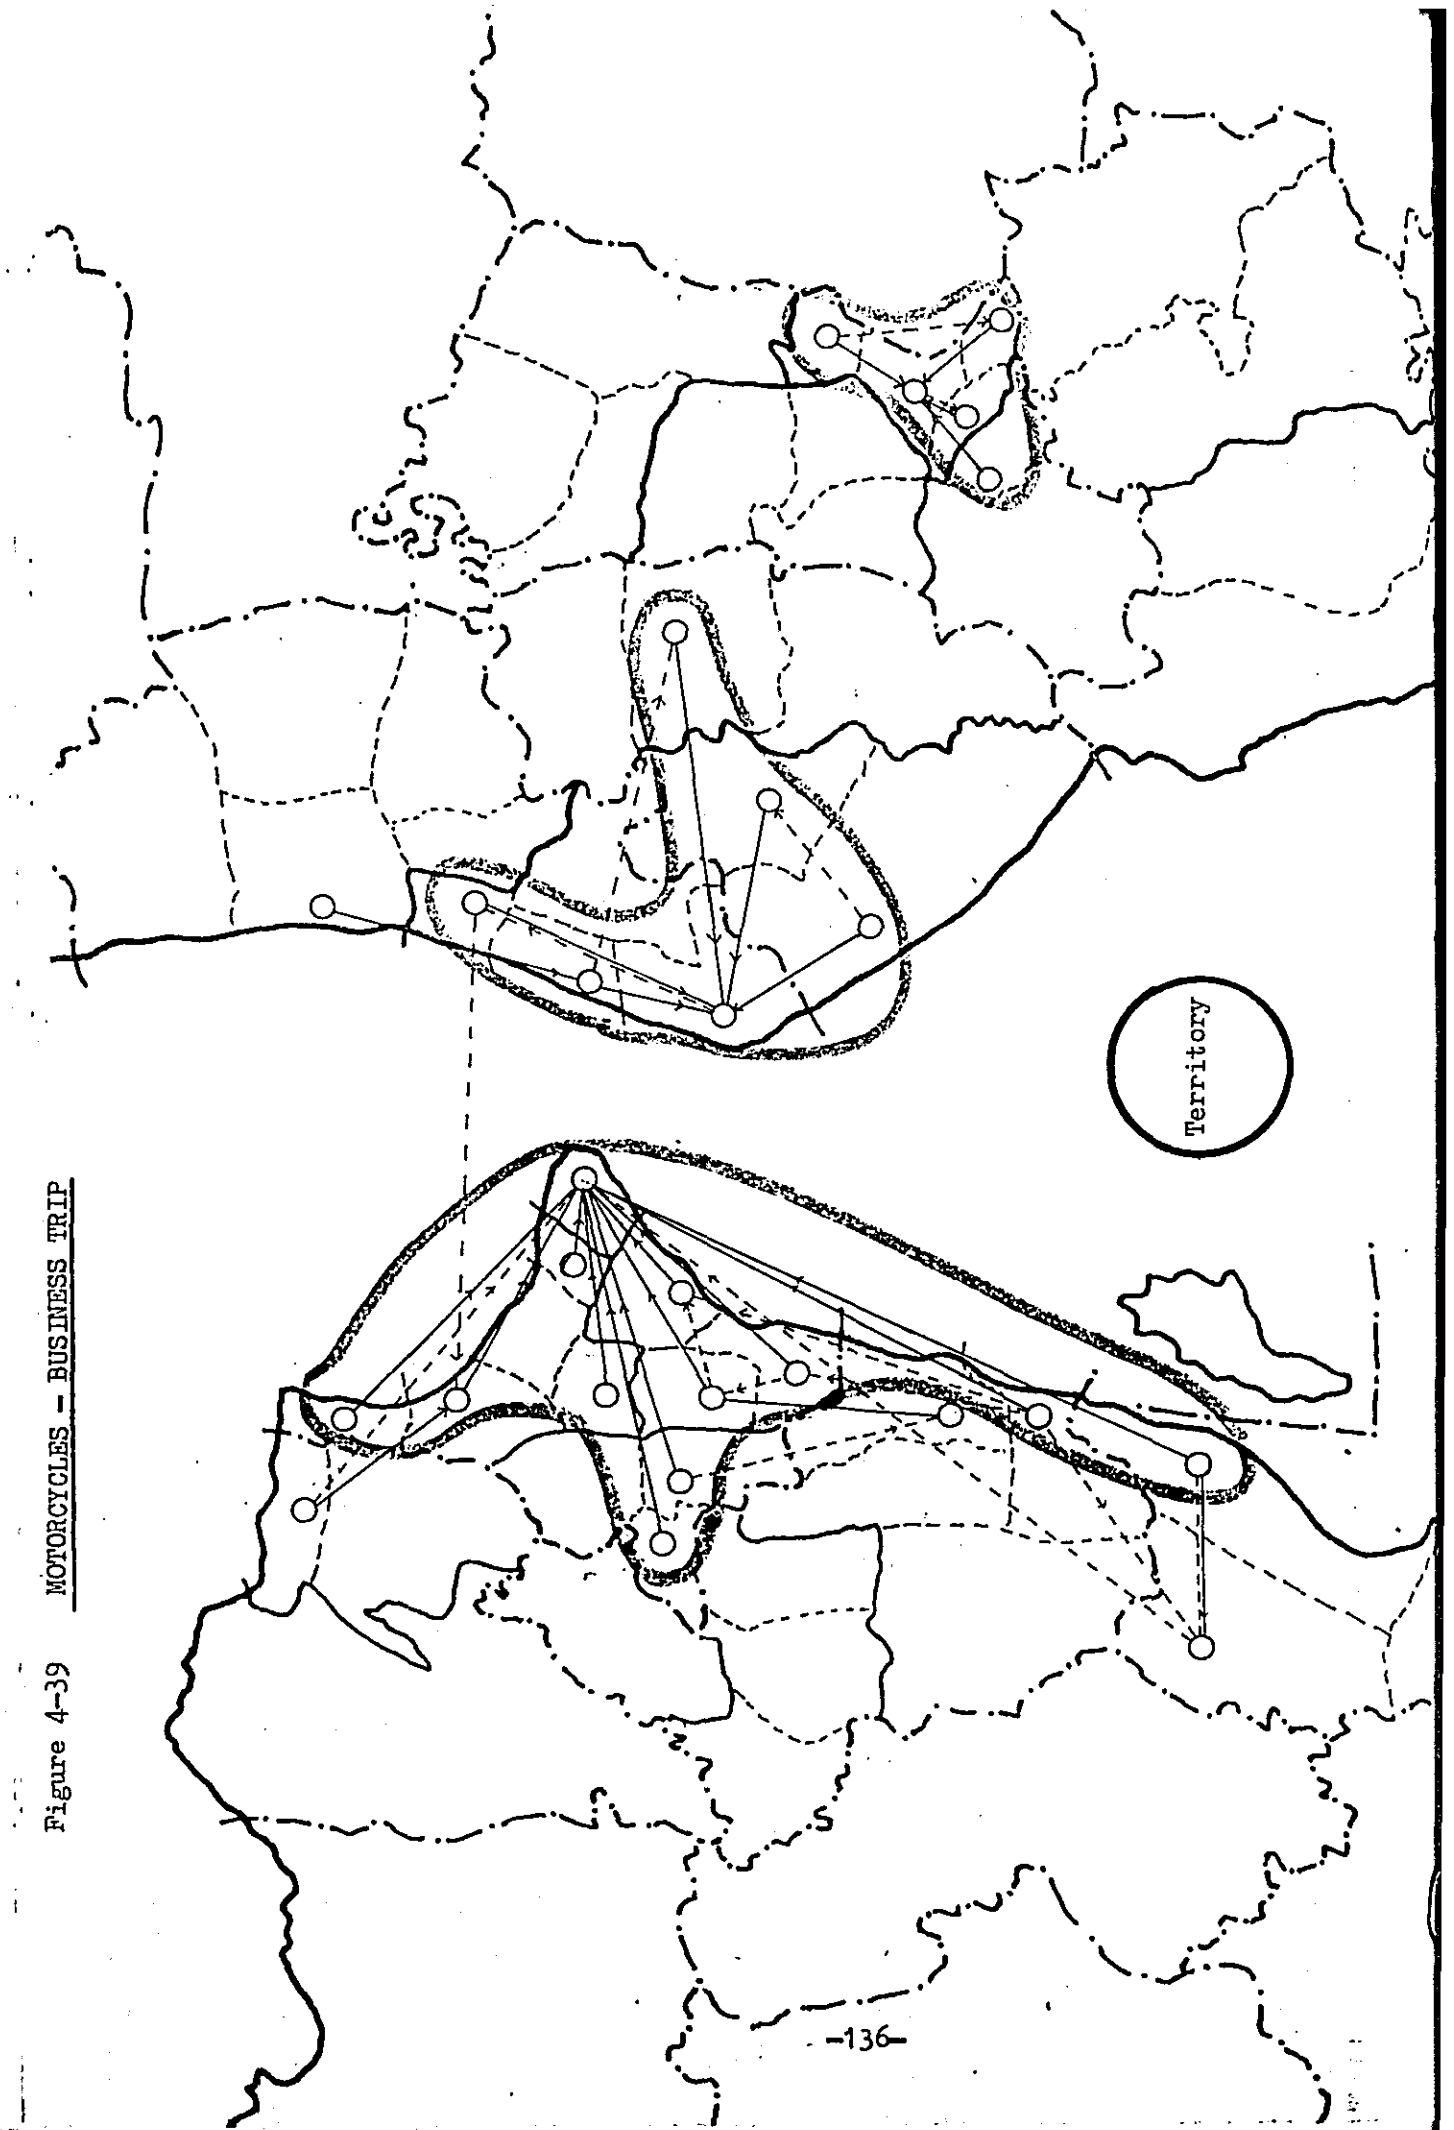

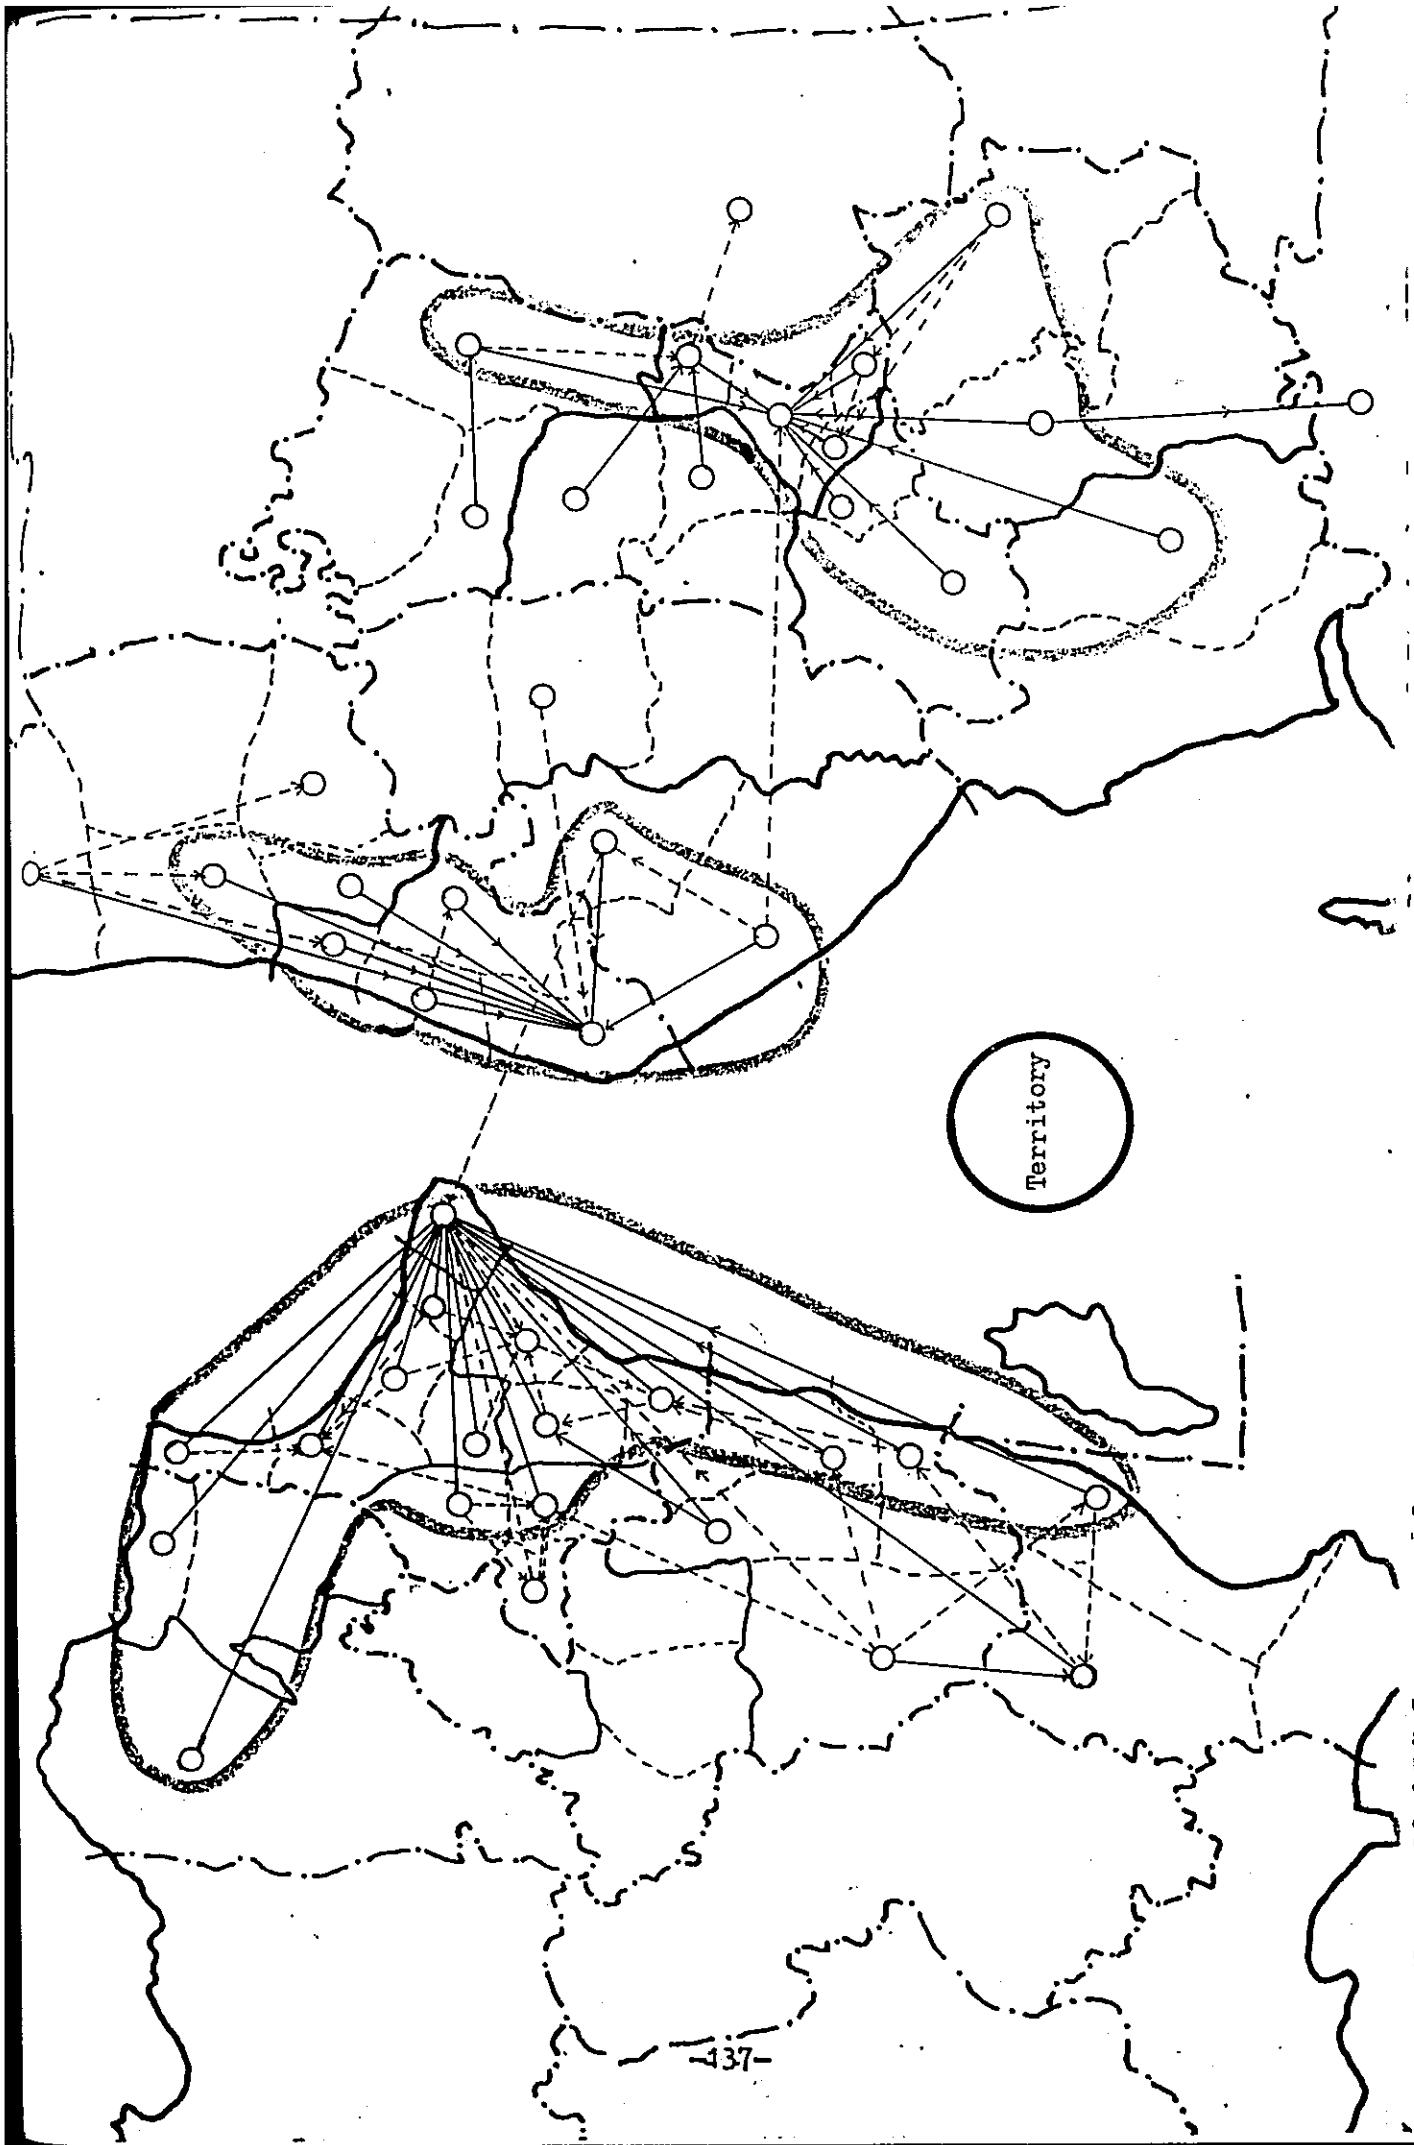

Figure 4-39 MOTORCYCLES - BUSINESS TRIP

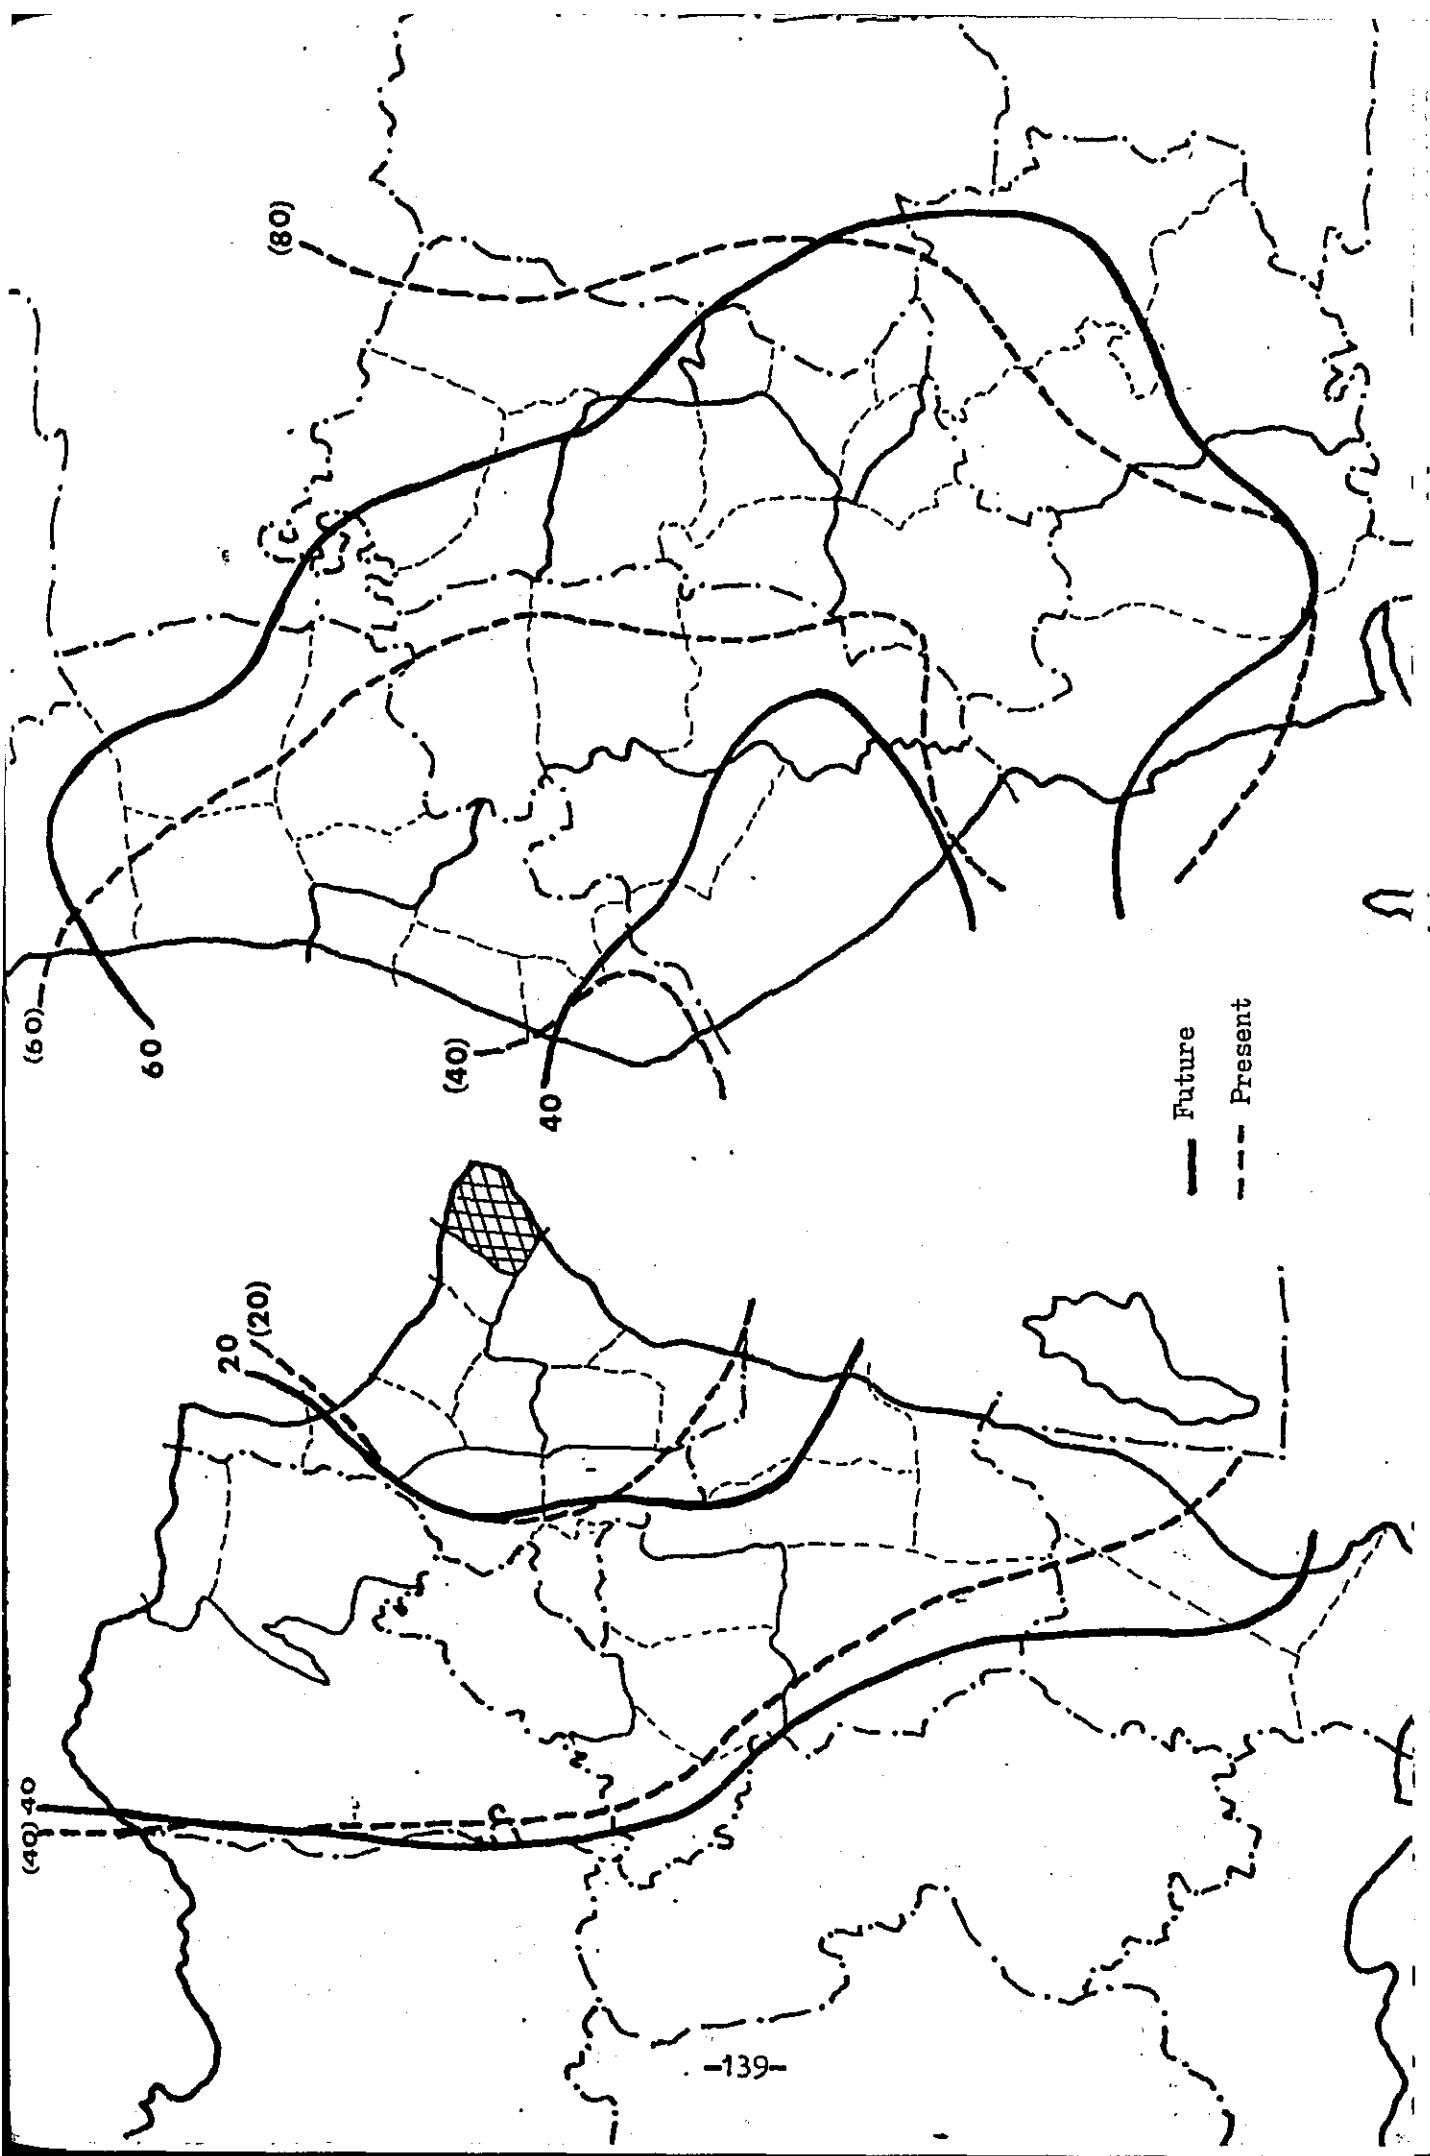

The time distance

Trip distribution is a result of trip generation and the time distance between the origin and the destination.

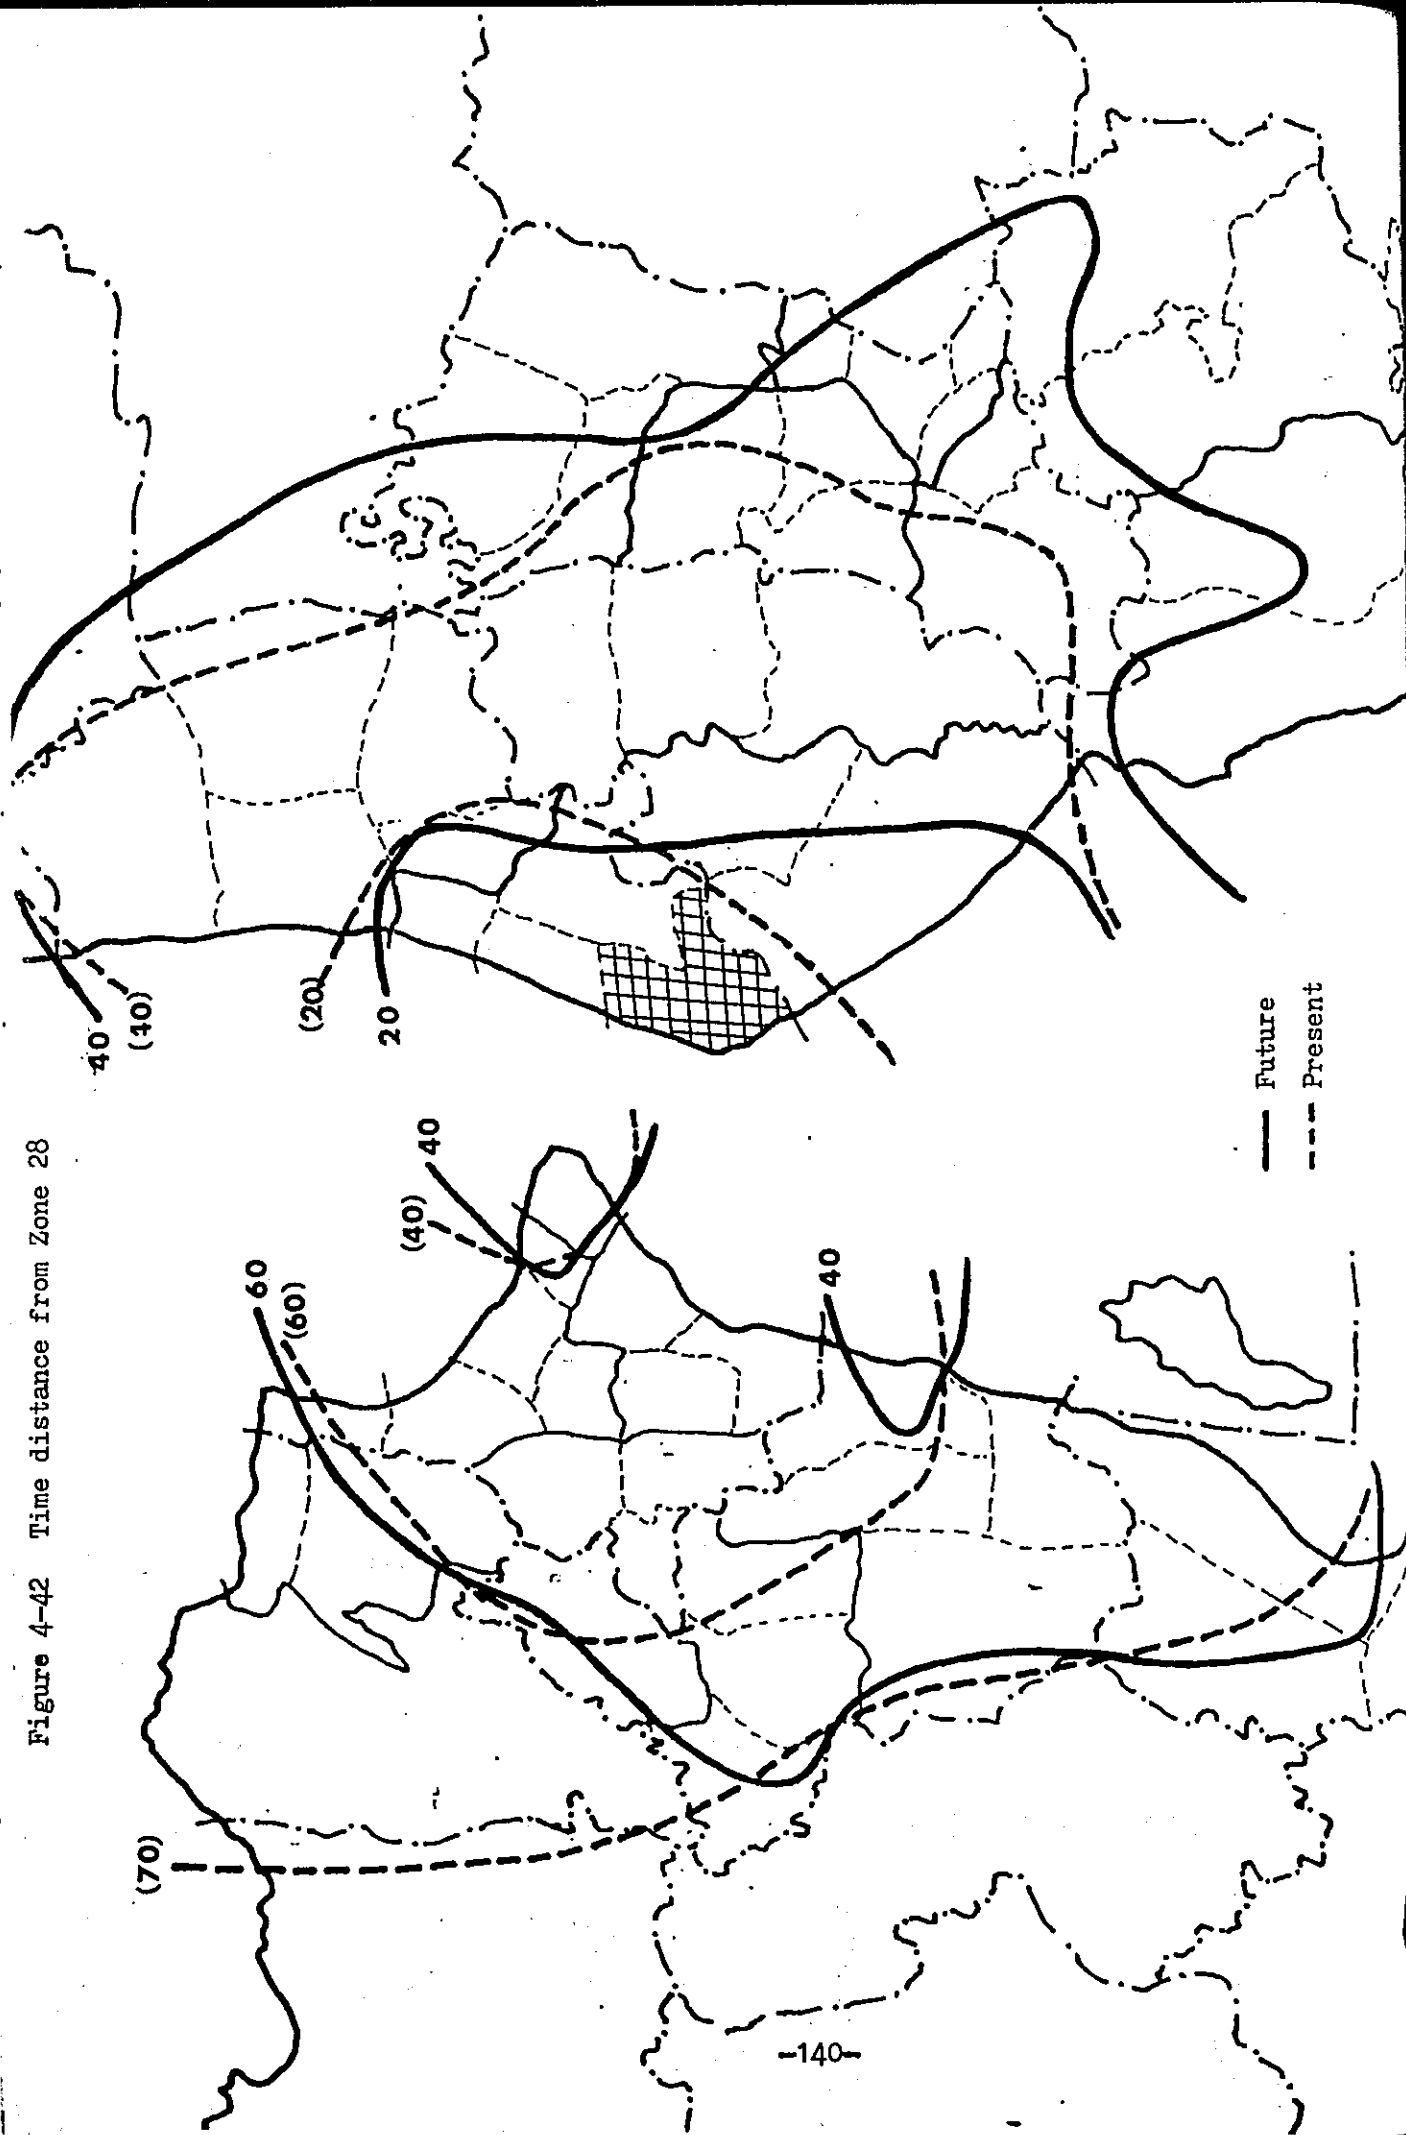

The time distance can be obtained from the car-owner Interview survey by subtracting the arrival time from the departure time and also from the road net work model.

In this study, a comparizon between both these values is done, after which the model method is made use of for the evaluation of the time distances between each zone pairs.

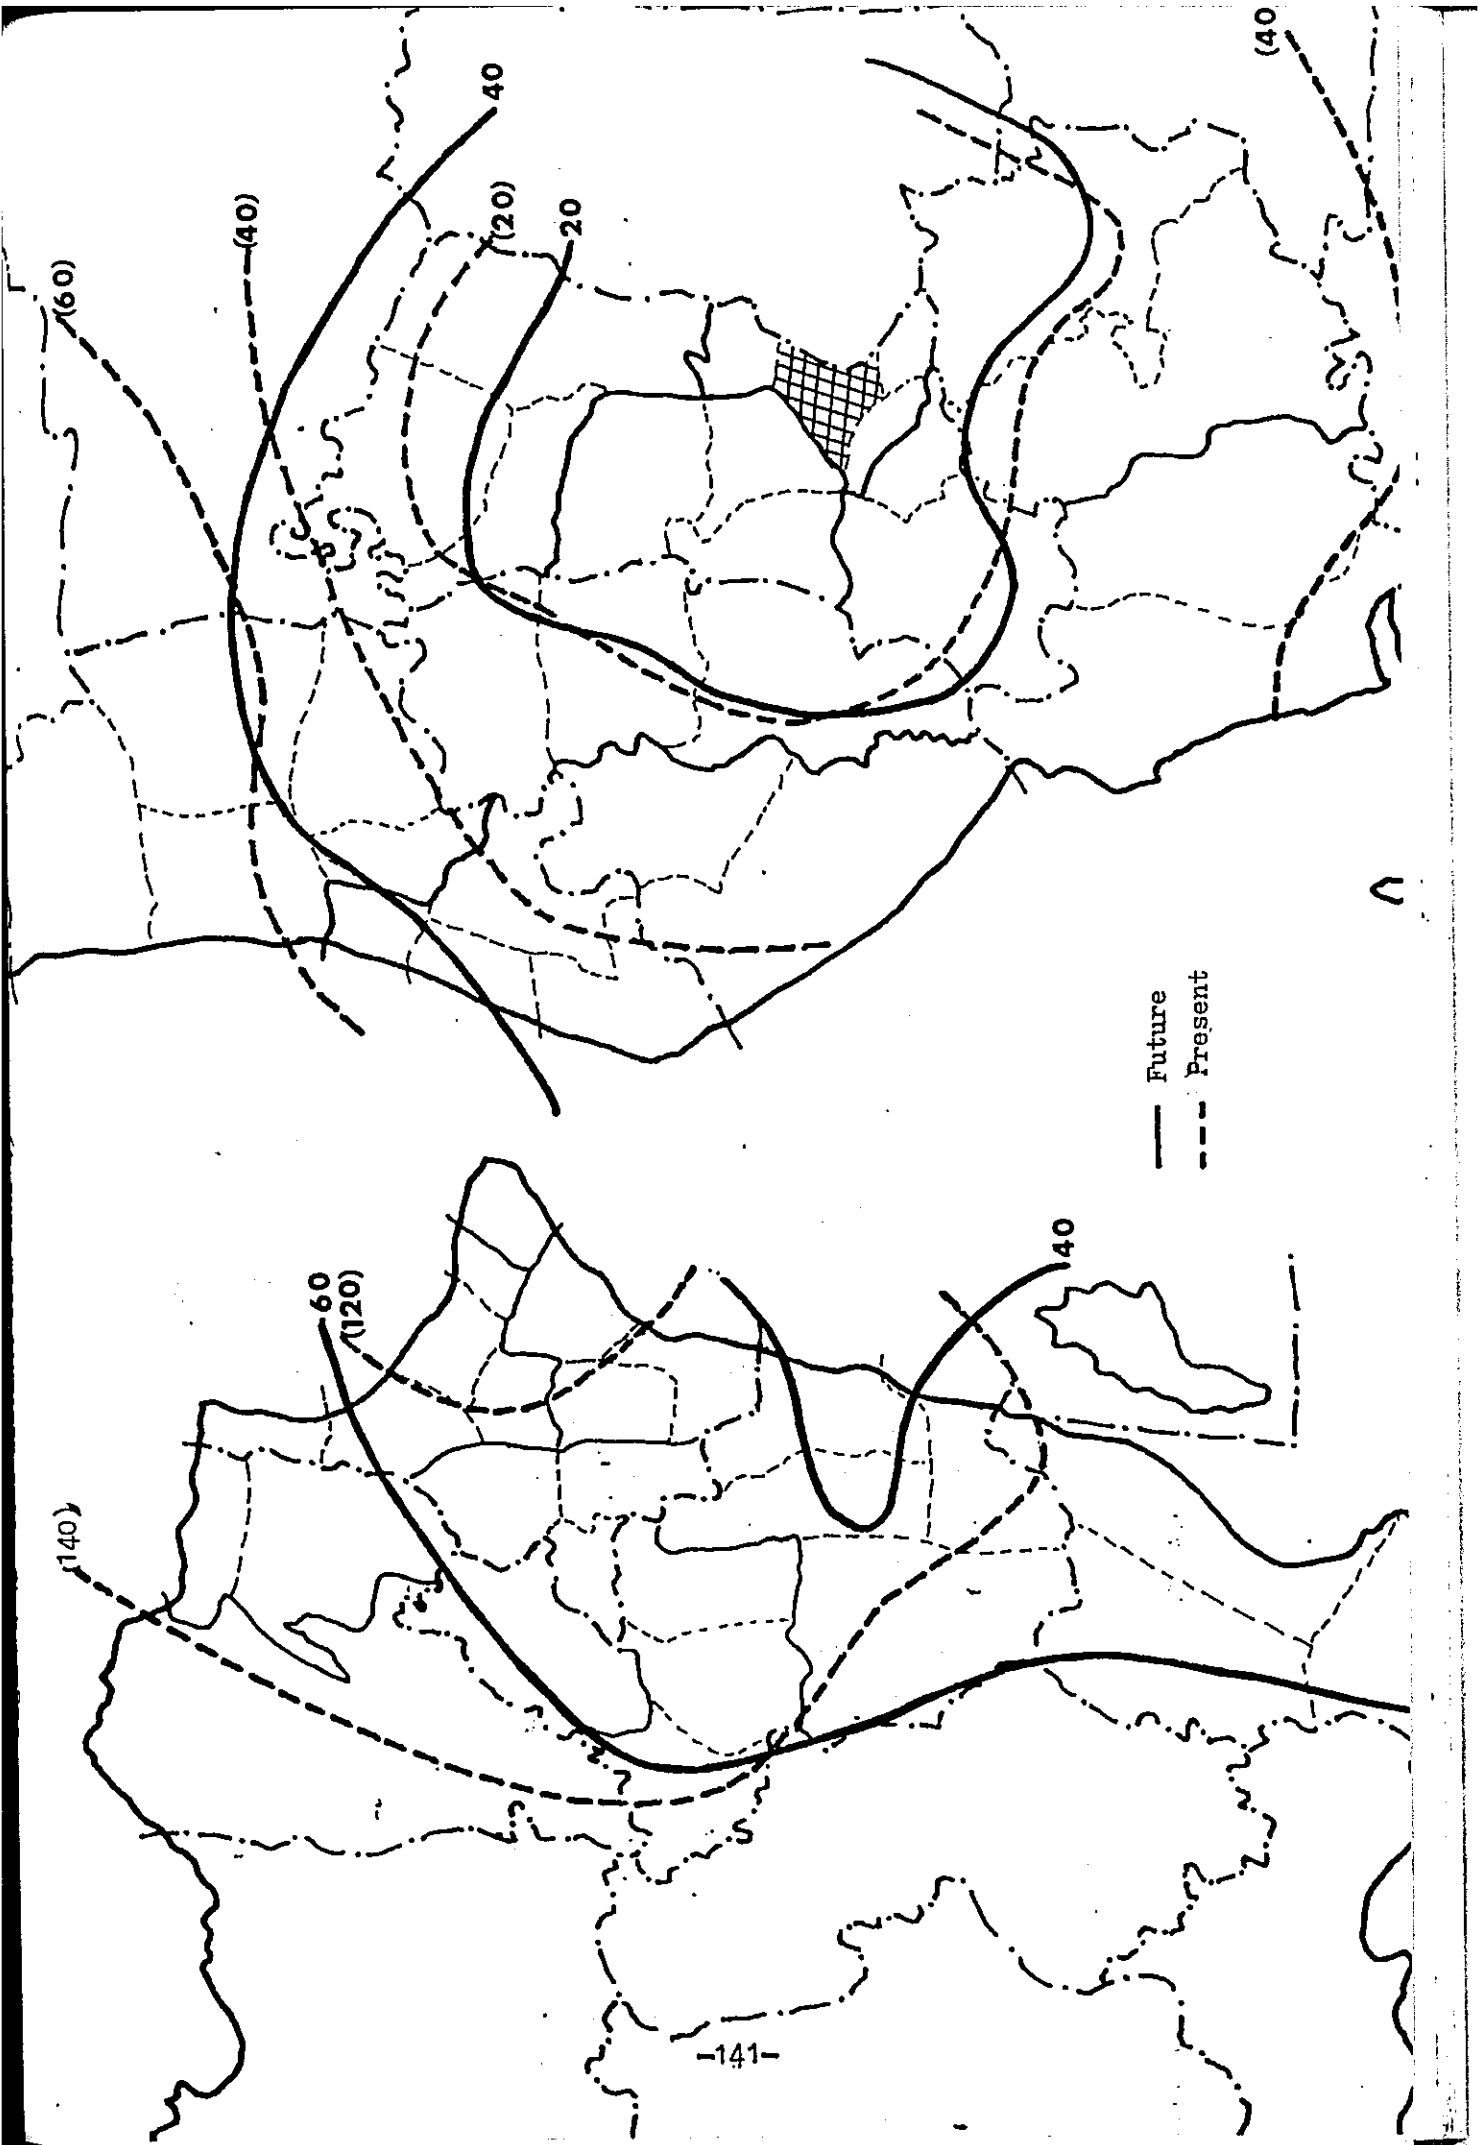

— Future  
- - - Present

The formulation of the trip distribution model.

Before formulating the trip distribution model, some trip distribution models which have been formulated by predecessors are first introduced.

(1) Method of trip distribution

Trip distribution models may be divided into two groups:-

- A. The Direct Method computes the number of trips between two zones within one step.
  - B. The Indirect Method distributes the total number of trips generated within a zone between all the zones of attraction.
- A. Methods for the direct calculation of trip distribution.

A-1 Gravity Model

The gravity model which has taken its name from a version of the "Lill's Reisegesetz" is as follow:

$$T_{ij} = \alpha \frac{g_i \cdot A_j}{t_{ij}^s}$$

- $T_{ij}$  : number of trips between zone i and j
- $g_i, A_j$ : the "mass" of zoned i and j respectively
- $t_{ij}$  : distance from i to j

While Lill considered his law a natural law similar to that of Newton's Law of Gravity, it is considered a simple way of giving a reasonable description of the travel pattern of a particular area at a particular time. Therefore, a large number of models have been established which more or were devived from the original model.

A-2 Multiple Regression Models

In a number of cases in California, Osofsky applied multiple regression to derive models for traffic between two zones of the following form:

$$T_{ij} = K_1 X_1 + K_2 X_2 + \dots$$

$T_{ij}$  : number of trips between zone i and j

$K_1, K_2$ : parameters for zone i

$X_1, X_2$ : variables referring to zone j

B. Methods for the Indirect Calculation of trip distribution.

B-1 Growth Factor Methods

The growth factor F is the ratio of the present to the future number of trips attracted to and generated from a given area.

a. Uniform Growth Factor

The simplest possible Growth Factor Model is,

$$T_{ij}' = T_{ij} \times F$$

$T_{ij}'$  : the future number of trips between zone i and j

$T_{ij}$  : the observed number of trips between zone i and j

F : a uniform growth factor for the entire area

b. The Average Factor Method

c. The Detroit Method

d. The Fratar Method

e. The Subjective Growth Factor Method

The contents of these models (b, c, d, e) are not included as their methods are similar to model a.

B-2 The present pattern method

This method typically makes use of the above mentioned growth factor models.

Therefore, to use this model the present O-D table is needed.

(2) The formulation of the trip distribution model.

For the purpose of estimating the trip distribution, the following two methods are representative. One is the present pattern method and the other is the model method. Usually, the former is used for short term estimation or when it is anticipated that the land-use pattern will not be subject to too much change.

On the other hand, the model method which is designed for adjusting to the change in land-use pattern, is suitable for long term estimation.

In our land-use plan, it is perceived that the future land-use pattern would be different from the present pattern. In addition to this, the main flow of traffic would be diverted because the linkage plan and the east-west highway plan would have reached fruition and consequently there would be a change

in the major road network. As a result of the above, the most popular method was chosen for our estimation and this is the gravity model method.

The gravity model is as follows:-

$$T_{ij} = \alpha g_i a_j \cdot t_{ij}^{-\delta}$$

$T_{ij}$  : number of trips between zone i and j.

$g_i$  : total number of trip generation in zone i.

$a_j$  : total number of trip attraction in zone j.

$\alpha$  : constant of proportion.

$\delta$  : exponent of gravity model

The exponents of the gravity model is estimated by the trip purpose or vehicle type through the least square method applied to the relationship between the present O-D tables and the present travel time of each zone pairs.

The results from using the model for all the zone pairs in the study area are as follows:-

Table 4-24 Formula of Trip Distribution

		The Formula of trip distribution
Car	trip to work	$T_{ij} = 1.147 \frac{A_i^{0.340} g_j^{0.424}}{t_{ij}^{0.624}}$
	business trip	$T_{ij} = 0.461 \frac{A_i^{0.402} g_j^{0.398}}{t_{ij}^{0.396}}$
	private trip	$T_{ij} = 0.749 \frac{A_i^{0.398} g_j^{0.404}}{t_{ij}^{0.576}}$
	trip home	$T_{ij} = 1.269 \frac{A_i^{0.415} g_j^{0.367}}{t_{ij}^{0.709}}$
Lorry		$T_{ij} = 1.737 \frac{A_i^{0.355} g_j^{0.381}}{t_{ij}^{0.635}}$
Taxi		$T_{ij} = 0.0998 \frac{A_i^{0.425} g_j^{0.413}}{t_{ij}^{0.115}}$
Bus		$T_{ij} = 0.523 \frac{A_i^{0.417} g_j^{0.407}}{t_{ij}^{0.419}}$
Motor-cycle		$T_{ij} = 0.237 \frac{A_i^{0.514} g_j^{0.510}}{t_{ij}^{1.100}}$

However, the use of one formula alone is not enough to explain the present traffic distribution. The reason is because the traffic pattern in Penang Island, Province Wellesley and across the strait each hand their unique characteristics. Therefore, the formulae are drawn up according to following areas.

Table 4-25 Table denotes formulae used for the internal and external areas of Penang Island and Province Wellesley.

D O		Internal area		External area	
		Penang Island	Province Wellesley	Penang Island	Province Wellesley
internal area	Penang Island	1	2	3	4
	Province Wellesley	5	6	7	8
external area	Penang Island	9	10	11	12
	Province Wellesley	13	14	15	16

The results of these procedures is that one trip distribution formula is made up of 16 formulae from each area pair.

Referring to figures 4-44, 4-45, 4-46, 4-47, 4-48, 4-49, 4-50 and 4-51 all values above the line are the actual values while those below the line are the estimated values using this model.

Traffic Assignment  
The procedure of traffic assignment

Through traffic assignment, the traffic volume on each road can be estimated. The procedure for traffic assignment is explained below.

(1) Each link of the road network has its own relationship between the traffic volume and the travel time. In this relationship the travel time increases with respect to the increase in the traffic volume already assigned. The travel time increases very rapidly as the traffic volume approaches the road capacity.

(2) The traffic demand of each O-D pair is assigned to the shortest route in relation to the travel time decided upon by the above relationship.

The so-called "all or nothing" method is used.

(3) The traffic demand of O-D pairs is divided into several lots and the travel time is calculated repeatedly according to the traffic volume already assigned on a link at the assignment of each lot.

The shortest route is obtained by the above calculations.

The above procedure is repeated until all the lots of each

O-D pair are assigned. Therefore, it rarely happens that the traffic demand of a particular O-D pair concentrates on a particular route.

The relationship between the traffic volume and the travel time is calculated from the following figures.

Fig: 4-52 Q-V Formula

The travel time is estimated by dividing the length of the link by the traffic speed on the link obtained in this relationship by applying the traffic volume which has already been assigned. In the case of the linkage and the ferry collect tolls, the toll is added to the travel time which corresponds to the toll paid. To convert the toll paid to the travel time, divide the toll by the time value.

4-5-2

#### Road network model

For the purpose of estimating the traffic assignment, we need the time distance between each zone pairs.

For this purpose, it is necessary to formulate the road network model. This model consists of links and nodes as shown in Fig. 4-53.

Fig: 4-53

#### (Node)

$i, j$  : node of generation and attraction.

This node represents the zone. Therefore, this node is arranged at the zone center.

• : node of connection

The connecting points between links.

#### (Link)

—— : actual link

This link represents the road.

---- : dummy link

This link is an assumed link done for the purpose of making traffic assignment an actuality.

To obtain the traffic volume which is very close to the traffic volume on each road, the Q - V formula is then applied on each link of one direction.

The Q - V formula expresses the relationship between the traffic volume and the travel time. It is known that the more the more the traffic volume increases, the more the travel speed decreases. Therefore the Q - V formula is determined by type of road as follows:-

Fig. : 4 - 54 Q - V formula

Traffic volume on each link for one direction.

Table 4 - 27 Q - V Formula for vehicle.

Area	No. of lane	Type of road	speed (miles per hour)				Capacity for one direction
			designed	limited	marginal	minimum	
Urbanized Area	4	new	50	30	15	5	22500
		existing	40	30	15	5	18000
	2	new	40	30	15	5	6000
		existing (A)	40	30	15	5	4000
		existing (B)	35	30	15	5	3500
		existing (C)	30	30	10	5	3000
	Sub-urban Area	4	new	60	40	15	5
existing			50	40	15	5	20500
2		new	45	40	15	5	7500
		existing (A)	40	40	15	5	5000
		existing (B)	35	35	10	5	4000
Highway	4	new	80	50	15	5	32000

Table 4 - 28 Q - V Formula for motorcycle.

Area	no. of lane	speed				capacity for one direction
		design	limited	margi- nal	mini- mum	
Urbanized Area	4	25	20	10	5	3500
	2	25	20	10	5	2500
Sub-urban Area	4	30	25	10	5	4000
	2	30	25	10	5	3000
High-way	4	30	25	10	5	4000

Concerning the ferry, a specific T - V formula is prepared especially for the waiting time which is expressed by the following formula. This formula is derived from our ferry survey.

Fig: 4-55 Waiting time for vehicles

Fig: 4-56 Waiting time for motorcycles

The method of estimating traffic volume.

Various methods can be used for the purpose of estimating traffic volume. However, it is possible to divide them into two methods, namely, the direct and the indirect method.

## (1) The objects in a traffic plan.

The objects in a traffic plan consist of various contents, ie. major roads, streets, intersections, traffic signals and other traffic facilities.

These objects can be seen from two points of views. One is from the point of view of the planning period while the other is from the point of view of the study area.

Generally speaking, the objects of a traffic plan have the following tendency, viz, the longer the planning period, the larger the study area. For example, the plan for a highway network requires the long-term aspect as well as the large study area because that plan must take into consideration the long-term prospects and the ability of the highway to cope with the movements of long trips.

On the other hand, improvement of intersections must be an urgent measure in the urbanized city. Therefore, the planning period must be short and the study area small enough to require only a short-term partial plan.

Therefore, it is not difficult to divide the objects of a traffic plan as follows:-

(2) The methods of estimating the traffic volume.

When drawing up traffic plans, it is usual that some estimation of future traffic volume is required and this is obtained from studying the traffic at the respective traffic facilities which are involved in the plan.

The method of estimating the traffic volume must correspond to the objectives of the traffic plan. For the purpose of dealing with urgent matters, it is useless if the target year is fixed too far in the future and it is also useless if a partial plan involves too large an area.

Taking the above-mentioned conditions into consideration it is better that for the short-term partial plan the direct method is used while for the long-term extensive plan the indirect method is more suitable. Of course another way is to combine both methods.

First, the contents of both methods are explained and then the features of these methods are shown.

A. The Direct Method.

For short-term estimation, the traffic volume can be estimated by making use of the trends of previous traffic volumes. In this instance, the future volume is estimated from the past-to-present traffic volume data directly without any transformation of the estimating factors.

This is the reason why this method is called the 'direct method'.

As the future demands are forecasted directly, it has the following advantages, viz, it is easy to estimate the volume, the estimation is unexpectedly accurate in so far as it is a short-term target.

However, by using this method, it is difficult to consider the environmental factors, as for example the land-use pattern, population distribution etc. To take these factors into consideration, we must study the extensive area, not the partial area.

Therefore this method is suitable for the short-term partial plan.

B. The Indirect Method.

This method uses certain means in the estimation of future traffic volume.

In the case of estimating the traffic volume on road networks the O-D table is almost the only means used. By using the O-D table, we can estimate the future traffic demands which also take into consideration the changes in the environment.

The increase of population in some zones can be seen in the increase in the trip generation in these zones. Also, the reduction of the distance between some zones through the improvement of roads can be seen in the increase in the trip distribution between these zones.

Therefore, by using the O-D table, we can broadly grasp the future traffic movements.

However, in order to estimate the O-D table, we must divide the area into several traffic zones. By virtue of this we cannot discuss the facilities found within the zones. Even if one zone includes many roads, these roads stand for one zone.

Therefore, the traffic plan is limited by the size of the traffic zone. This method is suitable for long-term extensive plans but unsuitable for detailed plans.

C. Conclusion.

The features of both methods are shown in the following table.

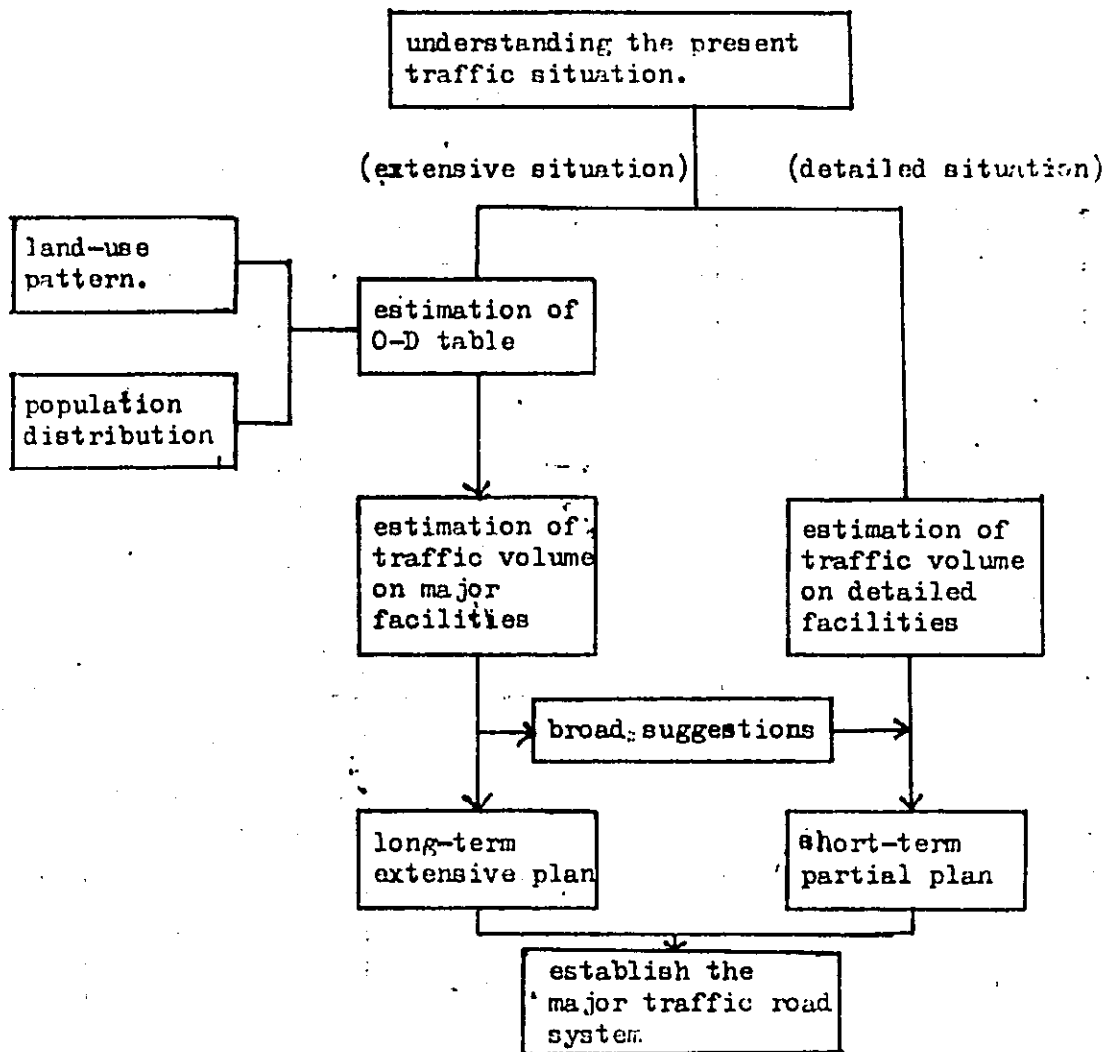

Table 4-28 Direct and indirect methods.

	Direct method	Indirect method
Functions	It is the way to estimate the traffic volume directly from the past-to-present traffic volume data.	It is the way to estimate the traffic volume by using the O-D table directly.
Advantages	(1) the detailed volume can be forecasted (for short-term estimation). (2) it does not entail too much working expenses.	(1) the extensive movement can be forecasted.  (2) it takes into consideration the changes in the environment e.g. the land-use pattern.
Disadvantages	(1) it is not suitable for long term estimations.  (2) it cannot grasp the movements in the extensive area.	(1) it is hard to do a detailed estimation. (it suffers from the limitations for the zone) (2) it entails heavy working expenditure.
Conclusion	it is suitable for the short-term partial plan.	it is suitable for the long-term extensive plans.

Taking the above conclusions into consideration, it would be suitable to use the indirect method for the main estimating work in order to establish the major traffic road system.

However, it is necessary to make use of the direct method in order to solve the problem of detailed facilities which the indirect method cannot cope with.

The above discussion can be expressed in following flow-chart:-

4-5-4

Results of present traffic assignment

As a conclusion, it is emphasised that, this traffic assignment was conducted through using the O-D table. Therefore, the size of the traffic zone limits the traffic assignment. The detailed traffic volume on each road cannot be obtained from this method and besides there is more traffic than there actually should be around the zone node which represents a particular zone because all the trip generation and attraction of one zone are generated and attracted to/from this node.

Therefore, when looking at the results of trip assignment, there constraints must be given consideration.

6. The premise

For the purpose of estimating future traffic demand, some premises must be first be laid down, that is, land-use by zone, population by zone and the cargo volume of port etc.

These figures have already been estimated by our population study and port study. In this section, these premises will be summarized.

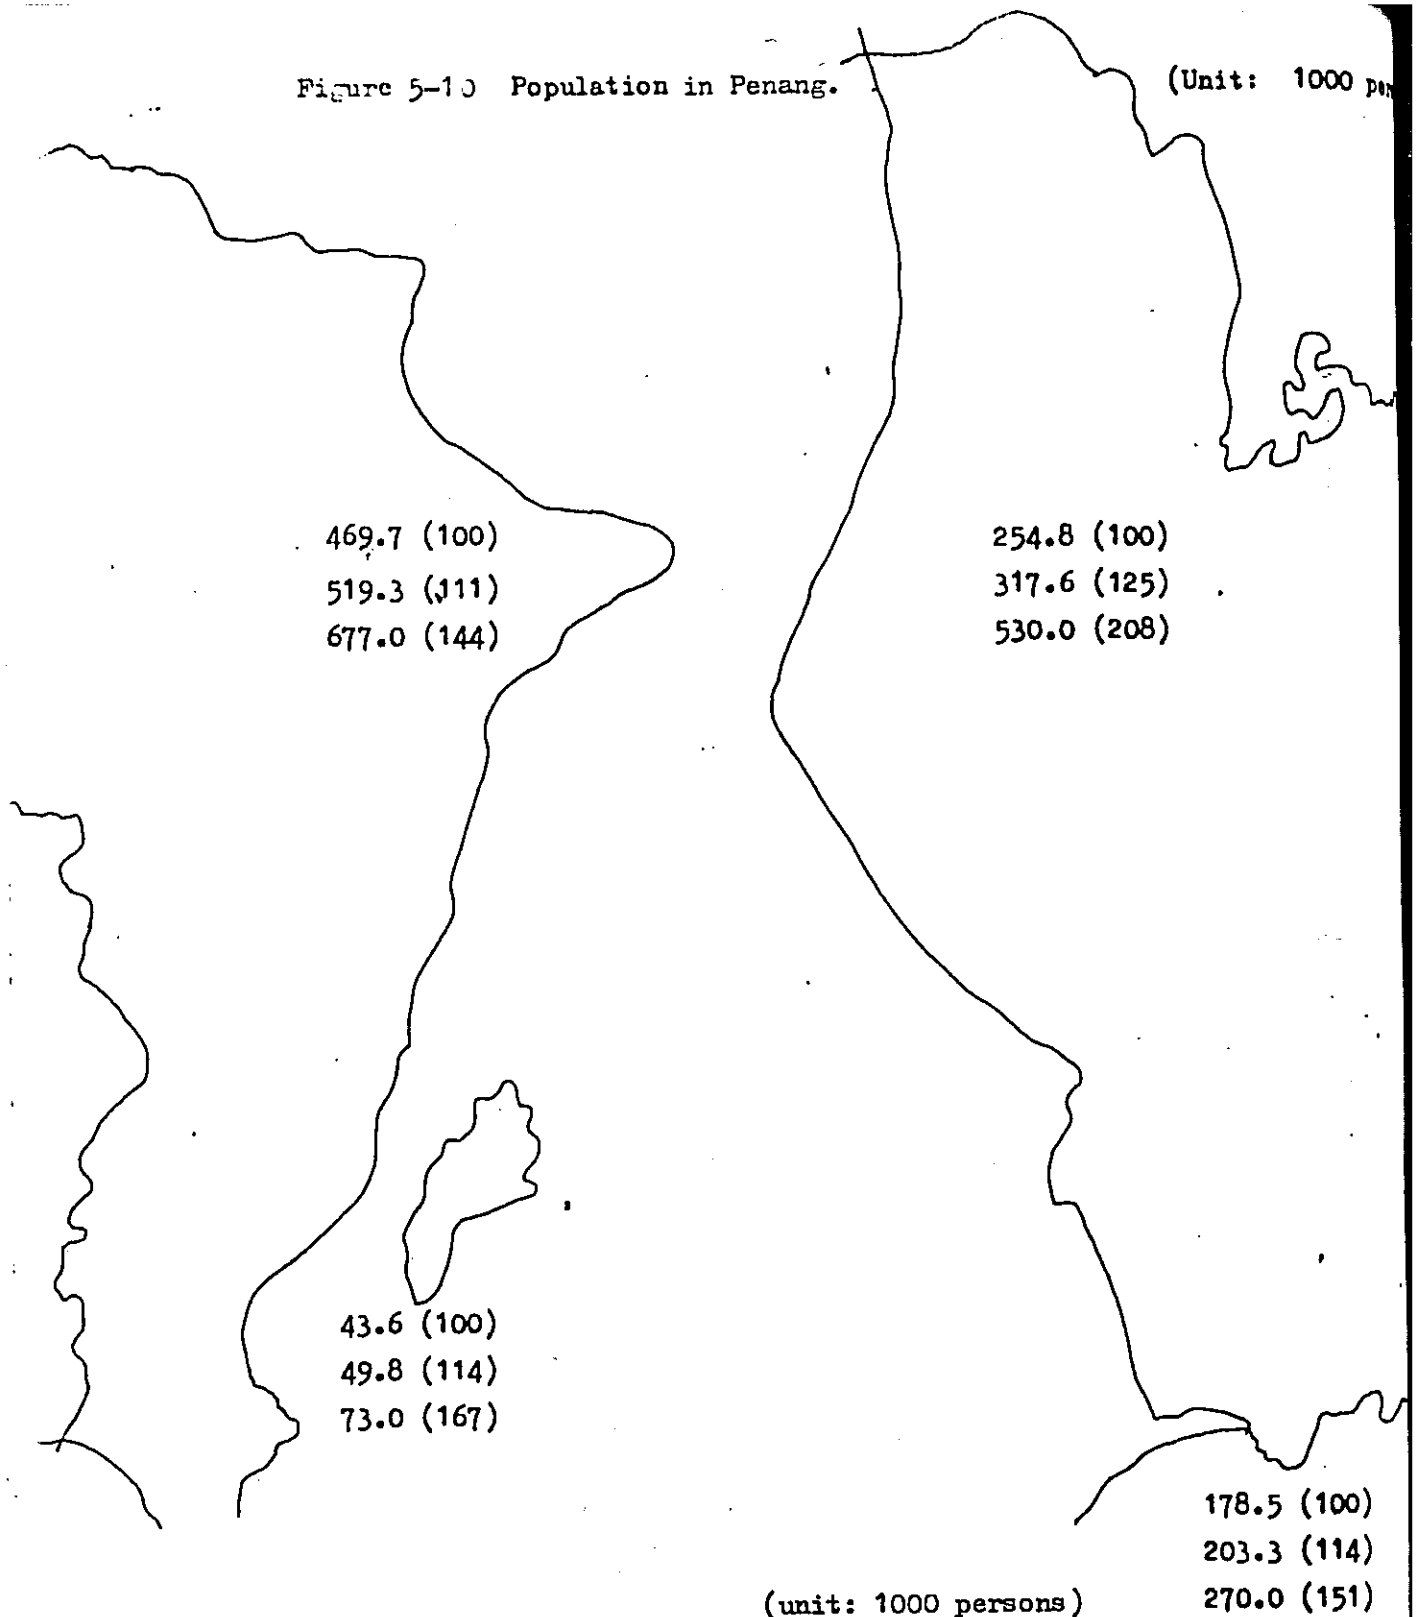

5-1

Population and employed population.

The following population is forecasted on the basis of the land-use pattern.

5-2 Comparison Between Penang Island and Province Wellesley.

The following figures show population as well as the employed population of Penang Island and Province Wellesley.

These figures indicate that in the future Province Wellesley will experience a great deal of development and also as a result of various existing conditions, the potential for development of Province Wellesley will be as great as that of Penang Island.

figure 5-6 The percentage of population as well as the employed population.

These figures suggest that the traffic volume in Province Wellesley will increased rapidly and the total number of trips will be close to that in Penang Island.

Therefore, traffic problems will arise in Province Wellesley as well in Penang Island.

The trend of the composition of population by large zone.

Year	Penang Island				Province Wellesley

5-3 Number of vehicles.

The trend in motor-vehicle ownership is one of the key-indicators of traffic growth and this is useful tool for evaluating past traffic trends and future volumes.

a. Motor-vehicle Registration Trend.

Recently, there has been a dramatic increase in the registration of motor-vehicles in Malaysia, specifically Penang State.

Table 5-3 and 5-4 show the trends for Peninsular Malaysia and Penang State.

Table 5-3 Motor-vehicle Registration Trend <sup>②</sup>  
(Peninsular Malaysia)

(unit : 100 vehicles)

Year Motor-vehicles <sup>①</sup>	1965	1970	1975	1977	Average annual percentage growth		
					1965-1970	1970-1975	1975-1977

Motor-cycles		27126	47432	89311	124984	11.8	13.5	8.8
Total		51926	82033	144536	203287	9.6	12.0	8.9
Population ③		697653	776124	864771	947530	2.2	2.2	2.3

Note: 1) excludes other vehicles

(eg. tractors, road-rollers, etc.)

2) source: R.I.M.V.

3) source: "Population Projections for the States of Peninsular Malaysia 1970 - 1980" Department of Statistics.

These tables show that the annual percentage growth was the highest for the period 1970 - 1975 after 1975 these figures decreased slightly. It goes without saying that the absolute figures are on the increase after 1975.

Table 5-6 Estimated vehicles volume by using least square method

Vehicles	1965	1970	1975	1979	Estimation	
					1985	2000
Cars	20975	28326	45578	65352	80428	127922
M/cycles	27126	47432	89311	124984	162685	269122

B-2. Estimation by using the relationship of the indicators concerned.

These indicators are usually the population figures, household size and income, accurate present and future values cannot be obtained during the study period. Therefore, only the population figures are used as a means of estimating the number of vehicles.

In figure which shows 'persons per vehicle type' we find that the figures are decreasing year by year and the shape of the graph looks like the exponential curve.

Figure 5-8 Persons per vehicle type.

- Car
- Motorcycle
- Car and Motorcycle

Table 5-7 Calculation of persons per vehicle type.

		1965	1970	1975	1979
Population A		697653	776124	864771	947530
Car B		20975	28326	45578	65352
Motorcycle C		27126	47432	89311	124984
Car & motorcycle D		48101	75768	124889	190336
Persons by vehicle type	B/A	33.3	27.4	19.0	14.5
	C/A	25.7	16.4	9.7	7.6
	D/A	14.5	10.2	6.4	5.0

Therefore, the exponential function is applied for the purpose of drawing the curve to estimate the future number of vehicles.

The results as obtained from using the exponential curve are as follows.

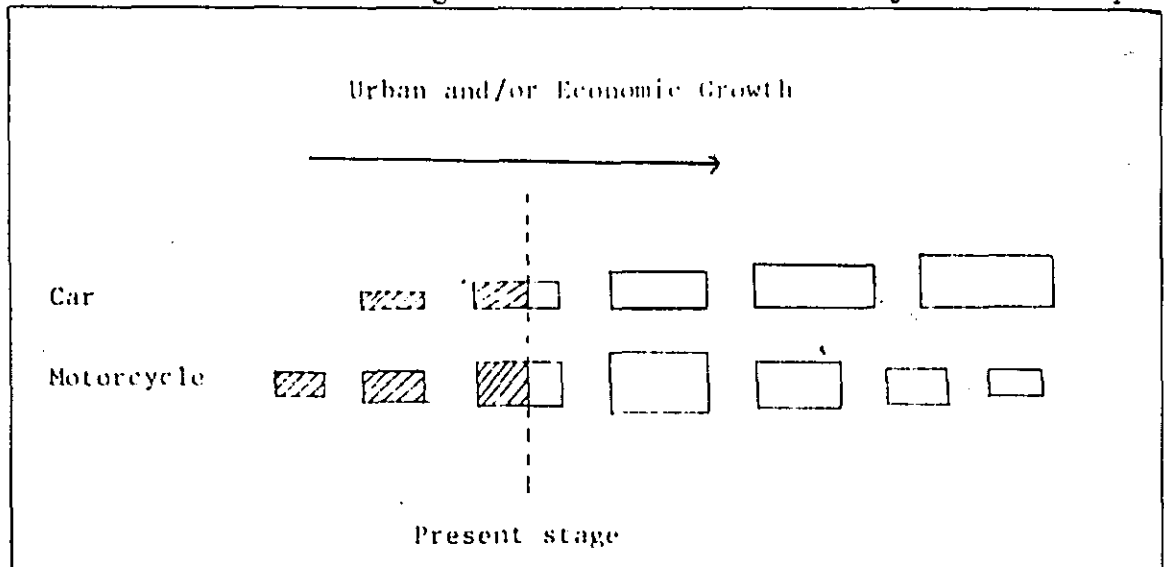

Table: 5-8 Persons per vehicle . (Unit : persons per vehicle)

	70	75	79	85	2000
Car	27.4	19.0	14.5	11.9	6.5
M/C.	16.4	9.7	7.6	6.5	5.0
Car + M/C.	10.2	6.4	5.0	4.5	3.6

A developed nation's urban history show that the modes of transport evolved parallel with the development of cities and urban incomes rose. It has been observed that Penang follows the evolutionary transition illustrated by the chart below:-

Figure 5-10 The trends of the growth of vehicles and motorcycles ownership

-  Previous Stage
-  Future Stage

The growth rate for motor-cycles does not seem to be following the present trend.

In time to come, it will be decreasing rapidly with the rate of urbanisation and economic growth.

The number of motor-cycles is estimated by subtracting the number of cars from the number of cars and motor-cycles.

Ownership for the other types of vehicles can also be estimated by the trend method.

The number of vehicles according to type is shown as follows:-

In time to come, it will be decreasing rapidly in live with the rate of urbanization and economic growth.

The number of motor-cycles is estimated by subtracting the number of cars from the number of cars and motor-cycles.

The results of the estimation are as follows:-

Table 5-9 Estimated motor-cycles volume (unit:1000 motorcycles)

	1970	1979	1985	2000
Population	776.1	947.5 (100)	1090.0 (115)	1550.0 (164)
Number of cars & m/cycles	75.8	190.3	231.9	360.5
Number of cars	28.3	65.4 (100)	91.6 (140)	161.5 (247)
(Persons per car)	(27.4)	(14.5)	(11.9)	( 9.6)
Number of m/cycles	47.4	125.0 (100)	140.3 (112)	199.0 (159)
(Persons per m/cycle)	(16.4)	( 7.6)	( 7.7)	( 7.8)

Ownership for the other types of vehicles can also be estimated by the trend method.

The number of vehicles according to type is shown as follows:-

Table 5-10 The number of vehicle in Penang State

Vehicles	1979	1985	2000

C. The number of vehicles in the study area.

The number of vehicles by area is estimated by distributing the increase in the number of vehicles since 1979 to each area according to the increase in the population by area since 1979.

Table:5 - 12 Number of vehicles  
in Internal Area. (unit: 1000 vehicles)

6 Estimation of future traffic demand.

6-1 Outline of the flow-chart for estimation and some definition.

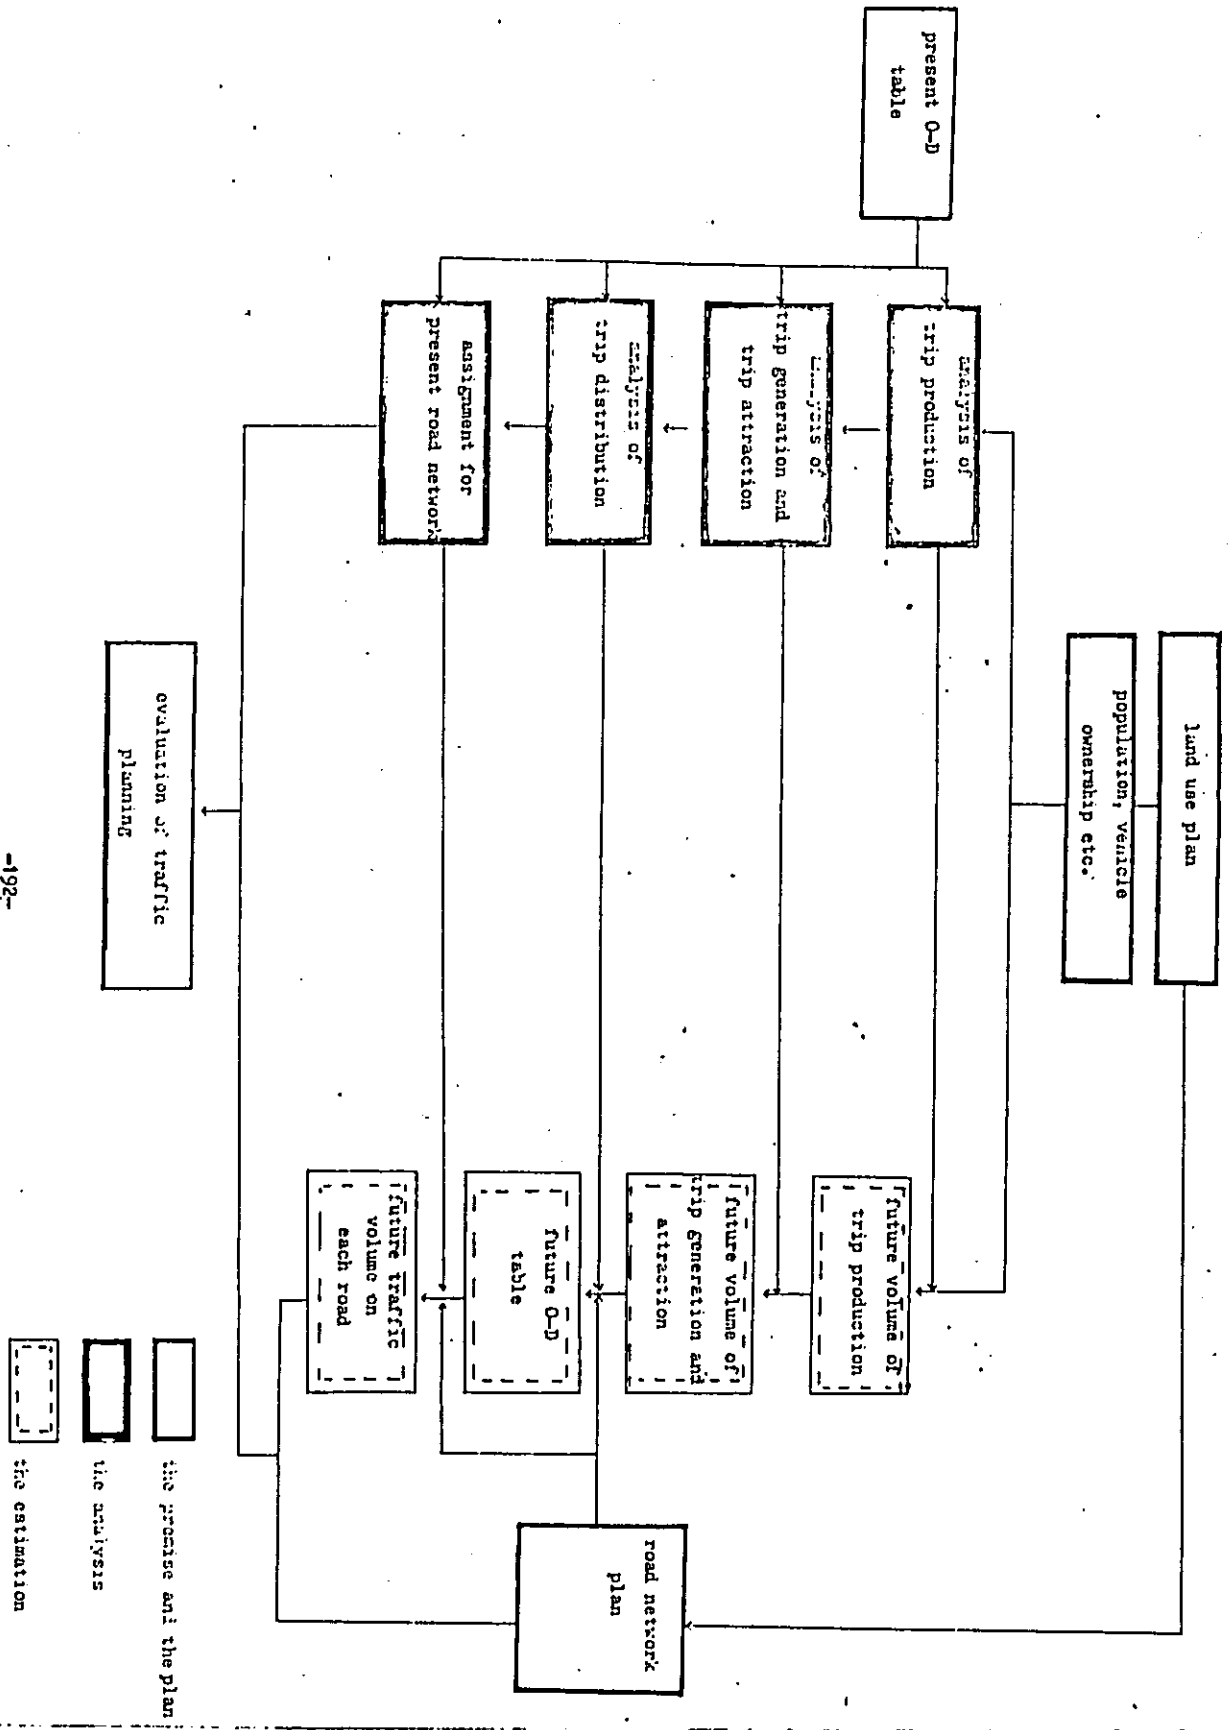

(1) Outline of the flow-chart.

The analysis of the present traffic situation was done in chapter 3. The estimation for the future traffic demand will be carried out on the basis of this analysis and the mentioned premise.

The flow-chart is as follows:-

The procedure of estimation are consisted with four steps, that is, trip production, trip generation and attraction, trip distribution (O-D table) and traffic assignment.

Figure 6-1 Flow chart for the future traffic demand estimation

(2) Some definition about traffic words

① Passenger Car Units

Vehicles of different types require different amounts of road space because of variations in size and performance. In order to allow for this in capacity measurements for roads and junctions, traffic volume are expressed in passenger car units (p.c.u.).

In 'Roads in Urban Areas' (published by Ministry of Transport Scottish Development Department), these p.c.u. are defined as following table.

In this study, we use the following figure as p.c.u. of urban standards.

Table 6-1 Passenger Car Units

Class of vehicle	Equivalent value in passenger car units (pcu's)			
	Urban standards	Rural standards	Round-about design	Traffic signal design
Private car, taxi, motor-cycle combination, light goods vehicle (up to 30 cwt. unladen)	1.00	1.00	1.00	1.00
Motor-cycle (solo), motor scooter, moped	0.50	0.75	0.75	0.33
Medium or heavy goods vehicle (over 30 cwt. unladen), horse-drawn vehicle	2.00	3.00	2.80	1.75
Bus, coach, trolley bus, tram	3.00	3.00	2.80	2.25
Pedal-cycle	0.33	0.50	0.50	0.20

('Roads in Urban Areas')

② Carriage-way Capacity

Approximately practical capacities of urban roads between junction are defined as following Table in above-mentioned report.

Table 6-2 Practical capacities of two-way urban roads

Effective width of carriageway in feet (excluding refuges or central reserve)	2-lane			3-lane		4-lane			6-lane			Remarks
	20'	22'	24'	30'	33'	40'	44'	48'	60'	66'	72'	
Description	Capacity in pcu's per hour for BOTH directions of flow					Capacity in pcu's per hour for ONE direction of flow						(for definitions of road see Section 2.1)
Urban motorway with grade separation and no frontage access								3,000			4,500	Applicable to the high category of distributor
All-purpose road with no frontage access, no standing vehicles permitted and negligible cross-traffic	1,200	1,350	1,500	2,000	2,200	2,000	2,200	2,400	3,000	3,300	3,600	Appropriate for all-purpose distributors
All-purpose street with high-capacity junctions and 'No Waiting' restrictions	800	1,000	1,200	1,600	1,800	1,200	1,350	1,500	2,000	2,250	2,500	Applicable to those distributor and access roads where access to development is frequent but capacity is not restricted by junctions
									2,200	2,450	2,700	

'Roads in Urban Areas'

The average daily capacity are calculated as following formula.

$$\text{Average daily capacity} = \frac{\text{practical capacity per hour}}{\text{ratio of peak-hour traffic demand}}$$

Concerning to the ratio of peak-hour traffic demand, 10.0% in 2-lane roads 12% in 4-lane roads are applied from traffic volume survey in Penang.

Therefore, the capacities are decided as follows;

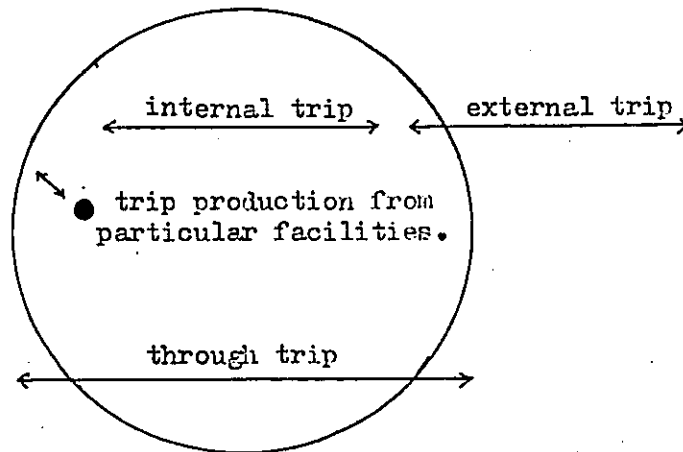

Table 6-3 The Daily Capacity

		Urbanized Area		Sub-Urban Area		High-way
		existing	new road	existing	new road	
2 lane	Capacity per hour	800 (22')	1200 (24')	1000 (22')	1500 (24')	
	Ratio of peak hour	10%	10%	10%	10%	
	Daily capacity	8000	12000	10000	15000	
4 lane	Capacity per hour for one direction	1200 (44')	1500 (48')	1350 (44')	2400 (48')	3000 (48')
	Ratio of peak hour	12%	12%	12%	15%	17%
	ratio of one direction	55%	55%	55%	55%	55%
	Daily capacity	36000	45000	41000	58000	64000

6.2 Estimation of Future O-D Table.

6.2.1 Trip Production

The future traffic volume, related to the study area is divided into the following types viz internal trip, external trip, through trip and trip production from specific facilities.

With regards to 'internal trip', 'external trip' and 'through trip', they have already been explained in chapter 1. 'Particular facilities' in this section means the new port, other port facilities and the airport.

These facilities will produce more traffic than that produced as a result of population increase. This is because there will be a rapid increase in the volume of cargo handled by the port and also in the volume of air passengers. Therefore, trip production from these facilities must be considered separately from the usual trip production.

(1) Internal trip

The internal trip production is estimated by multiplying the number of vehicles with the unit trip production already determined in this analysis.

Table 6-4: Number of Trip in Internal Area

		Car	Lorry	Taxi	Bus	Sub-Total	M/C
Number of Vehicle	1979	59.3	9.4	0.4	0.9	69.9	105.1
	1985	79.8	13.0	0.6	1.2	94.6	124.0
	2000	202.6	28.8	1.9	2.5	235.7	155.0
Number of Trip	1979	236.0	28.4	2.7	19.0	286.1	397.3
	1985	312.9	39.1	4.8	24.7	381.5	437.7
	2000	710.7	86.7	15.3	51.5	864.2	449.5

However, some explanation is needed regarding the unit trip production of cars and motor-cycles.

As future number of cars and motor-cycle shows, these number will increase with the increase in population and the level of income.

The average possession number per person about private car will increase from 0.08 in 1979 to 0.10 in 1985 and 0.17 in 2000. Also, those number about motor-cycle will be 0.15 in 1985, 0.14 in 2000 from 0.14 in 1979.

In any case, the ownership of private cars and motor-cycles per person and per household will increase without doubt.

As the number of private cars and motor-cycles increase, the unit trip production per day will decrease. It is proved by the results of many surveys in advanced countries.

Therefore, in the estimation of the volume of trip production by private cars and motor-cycles, we consider these situation and the unit trip production are settled to be slightly decreased figure from present one according to the increased ratio of car and motor-cycle possession.

Concerning to other type of vehicle, the unit trip production are settled to be same figure in present.

Table 6-5 The Unit Trip Production (Unit : trips per vehicle)

	1979	1985	2000
Private Car	3.98	3.92	3.51
Motor-cycle	3.78	3.53	2.90

(2) Trip production from specific facilities.

The specific facilities in this section refer to the port and the airport.

The future cargo volume is estimated by using the relationship between the cargo volume and the Gross Domestic Product (G.D.P.).

Table 6-6 Cargo Tonnage in Penang Port (Unit : 1000 tons per year.)

	1979	1985	2000
Cargo Tonnage in Penang Port	5.12 (100)	7.94 (155)	12.5 (245)

The cargo volume by wharf for 1985 and 2000 estimated by using the data from the Penang Port Commission.

Table 6-7 Future cargo volume by cargo type and wharf. (Unit:1000 tons)

Location of Wharf	cargo type	year	1985	2000
Penang Island	Commodity		535	550
	Fuel oil		85	150
	total		623	700
Butterworth	Commodity		2513	3090
	Fuel oil		-	-
	total		2513	3090
Prai River Area	Commodity		739	740
	Fuel oil		-	-
	total		739	740
Prai Marginal Area	Commodity		728	1130
	Fuel oil		650	1120
	total		1378	2250
New Development Area	Commodity		1296	3500
	Fuel oil		1391	-
	total		2687	3500
total	Commodity		5814	9230
	Fuel oil		2126	3270
	total		7940	12500

Trip production from these wharfs is estimated on the basis of their carrying capacity by each commodity type. The results are shown in the following table.

Table 6-8 Trip production by wharf (Unit : 1000 trips per day)

Location of wharf	1979	1985	2000
Penang Island	3.6	4.1	5.3
Butterworth	7.9	9.0	13.0
Prai River Area	1.7	1.9	3.9
Prai Marginal Area	2.3	2.6	2.9
New Development Area	-	4.0	15.9
Total	15.5 (100)	21.6 (140)	41.0 (213)

The Passengers bound for and departing from Penang Island are increasing at a rapid rate and in the time span of one decade, the growth rate shows a 5 times increase.

Table 6-9 No. of passengers (bound for/departing from Penang Island) Unit: 1000 persons per year)

Year	Passenger	Year	Passengers
1968	137.8	1974	497.0
'69	162.9	'75	560.6
'70	198.7	'76	588.6
'71	233.4	'77	635.6
'72	286.6	'78	685.5
'73	441.2		

The future volume of passengers is estimated by the regression equation.

Table 6-40 Future volume of passengers  
(Unit : 1000 persons per year)

	1970	1975	1978	1979	1985	2000
Passengers	198.7 (100)	560.6 (282)	685.5 (345)	705.5 (355)	1129.5 (568)	4234.0 (2131)

Trip production from the airport is estimated from the growth rate of passengers as shown below:-

Table 6-11 Trip production (persons per day)

	1979	1985	2000
passengers per day	1930 (100)	3090 (160)	11600 (600)
trip production of vehicles	2165*	3460	13000

\* From our Traffic Generation Survey (14.6.1979)

Fig : 6-3 Trip production from Air Port.

(3) External trips and through trips.

The rate of growth of external trips and through trips in the future is dependant upon the rate of growth of the external area.

With regards to Penang Island, the rate of growth of external trips is estimated by using the growth rate population in the external area of Penang Island.

In Province Wellesley on the other hand, the rate of growth of external trips is calculated by using the estimation from the 'Feasibility study of Federal Route 1' and the 'Feasibility study of the East-West Highway.'

The result of the estimation is as follows:-

Fig. : 6-4 External and Through trips.

(4)

Total number of trip related to the study area.

The estimation for the number of trips was conducted separately according to the type of trips. The summary of these estimation are as follows :-

Table 6-12 Total number of trips (unit: 1000 trip perday)

		1979	1985	2000
vehicles	internal trip	286.1	381.5	864.2
	external and through trip	35.3	51.1	144.4
	trip production from specific facilities	—	(6.1) (1.3) 7.4	(25.5) (10.8) (36.3)
		321.5	440.0	1044.9
motorcycles	internal trip	397.3	437.7	449.3
	external and through trip	25.1	27.7	28.6
		422.4	465.3	477.9

6-2-2 Trip generation and attraction.

(1) Future trip generation and attraction.

Future volume of trip generation and attraction is calculated by the trip generation and attraction model which is derived from the present traffic and population data.

The results are as follows:-

Fig:6-5 The relationship with trip generation and population

(unit:1000 p.c.u, person)

Fig: 6-6 Trip generation in Penang Island and Province Wellesley

(unit:1000 trips)

LEGEND

6-2-3 Future O-D table

Number of trips in each traffic type.

O-D tables for the future are estimated by using the future trip generation, trip attraction, and distance between each zone pair together with gravity model which is derived from the present traffic data.

Table:6-15 Number of trip in each traffic type

(Unit:1000 trips)

(unit: 1000 P.C.U.)

### (3) Desired Assignment

For the purpose of grasping the traffic movement approximately, the desired assignment are conducted using the method of simple assignment. This way is that the traffic demand of each O-D pair (in this case middle zone pair) is assigned to the shortest desired route according to the distance. The growth rate of traffic demand on major section estimated by the desired assignment are as follows;

From these figures, the following can be observed:

(1) In Penang Island, the traffic movement between George Town and Bayan Lepas will become greater. (Section C). The traffic movement in 1979, 1985 and 2000 are 63,000 106,000 and 239,000 respectively.

(2) In Province Wellesley, the traffic movement between Butterworth, Seberang Prai and Bukit Mertajam (Section F) will be increased remarkably from 41,000 to 73,000 in 1985, 20,400 in 2000.

Fig. : 6-10 Traffic demand on major section (Unit : 1000 p.c.u.)

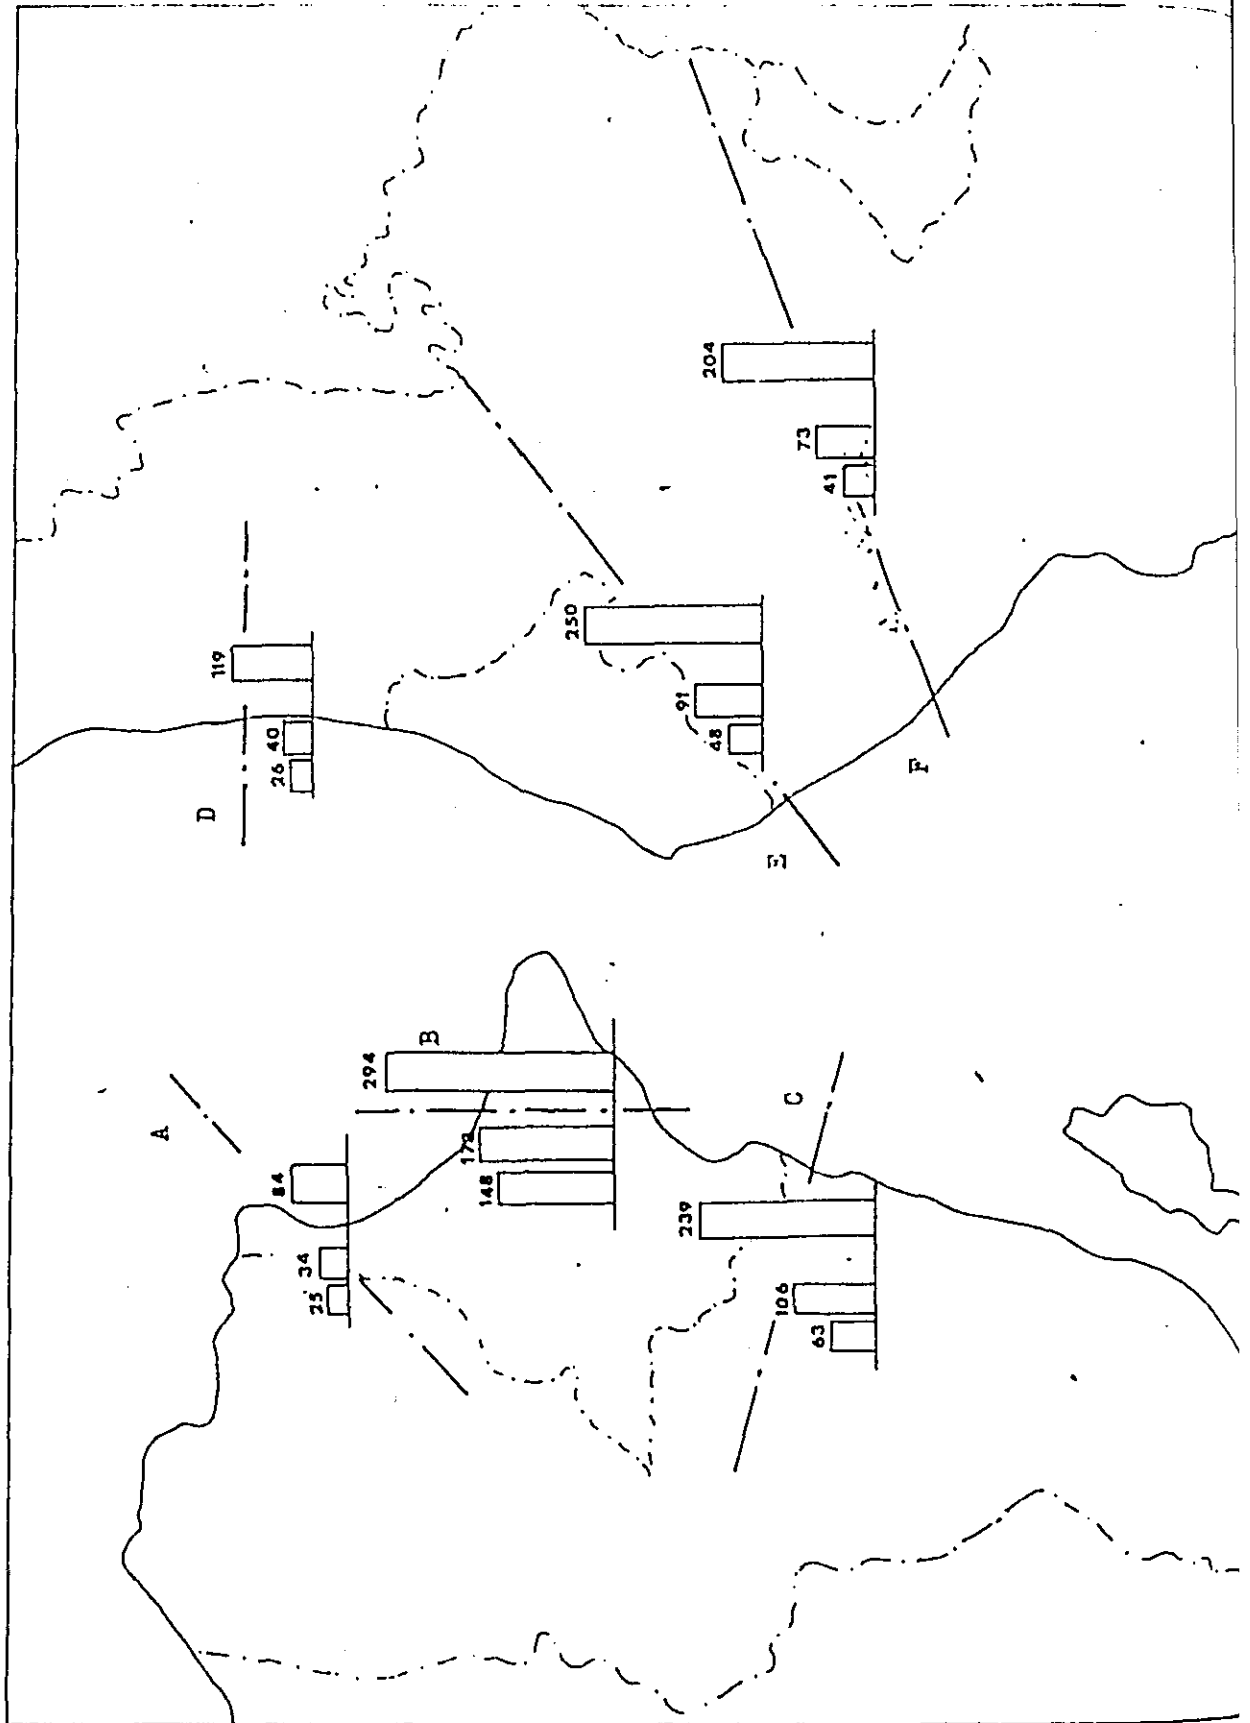

Table 6-19 Traffic Demand on Major Section

(Unit:1000 trip P.C.U)

Section Year		Penang Island			Province Wellesley		
		A	B	C	D	E	F
1979	Vehicles	15.7	85.7	35.9	14.6	27.2	20.4
	M/C	11.1	88.7	35.7	13.9	29.2	28.0

(4) The traffic volume across the Straits

The traffic volume over that unique section, viz cross the Straits is estimated as follows:-

Table 6-20 Traffic volume across the straits (unit: 1000 vehicles/  
motorcycles)

		1975	1979	1985	2000
vehicles	a	4.7	10.8 (100)	(14.6) (135)	(30.1) (278)
	b	-	-	(19.2) (178)	(52.9) (490)
motor- cycles	a	10.0	13.0 (100)	(14.4) (111)	(18.5) (142)
	b	-	-	(140.7) (113)	(15.8) (122)

a: simple trend method

b: results from distribution estimation

From the results, the induced trips brought about at the completion of the linkage can be obtained. In 1985, these trips will total 6,000 p.c.u. but by the year 2000 they will total 28,000 p.c.u.

From this, we can deduce that the effects of the linkage will be quite large.

Concept of the Transport Plan

The future O-D table which are described in chapter 6 are estimated according to the demand of vehicles. However, the actual appearance of the traffic are affected by many restriction and alternative transport, that is, if there are no parking area, vehicle traffic will decrease and if there are some superior transport which speed is faster than vehicles, some vehicle will divert to the new transport.

Therefore, we must consider some factors which are related to the traffic volume. In this chapter, some alternative transport plan are considered and some estimation are executed by the transport plan. ✓

## (1) The transport plan

The transport plan are planned as following 3 (three) steps.

## Plan B

In this plan, the restriction about parking demand and the alternative transport which are represented by bus exclusive lane are considered.

## Plan C

In this plan, the new transport system which is imagined as the Lightway Rail System is considered on Penang Island in addition to Plan B.

## Plan D

In this plan, the control of parking demand and the car pooling system are considered.

The calculation are executed as follows:-

Year	Plan - B	Plan - C	Plan - D
1985	execution		
2000	execution	execution	execution

Fig. : 7.1 Alternative Plan - B

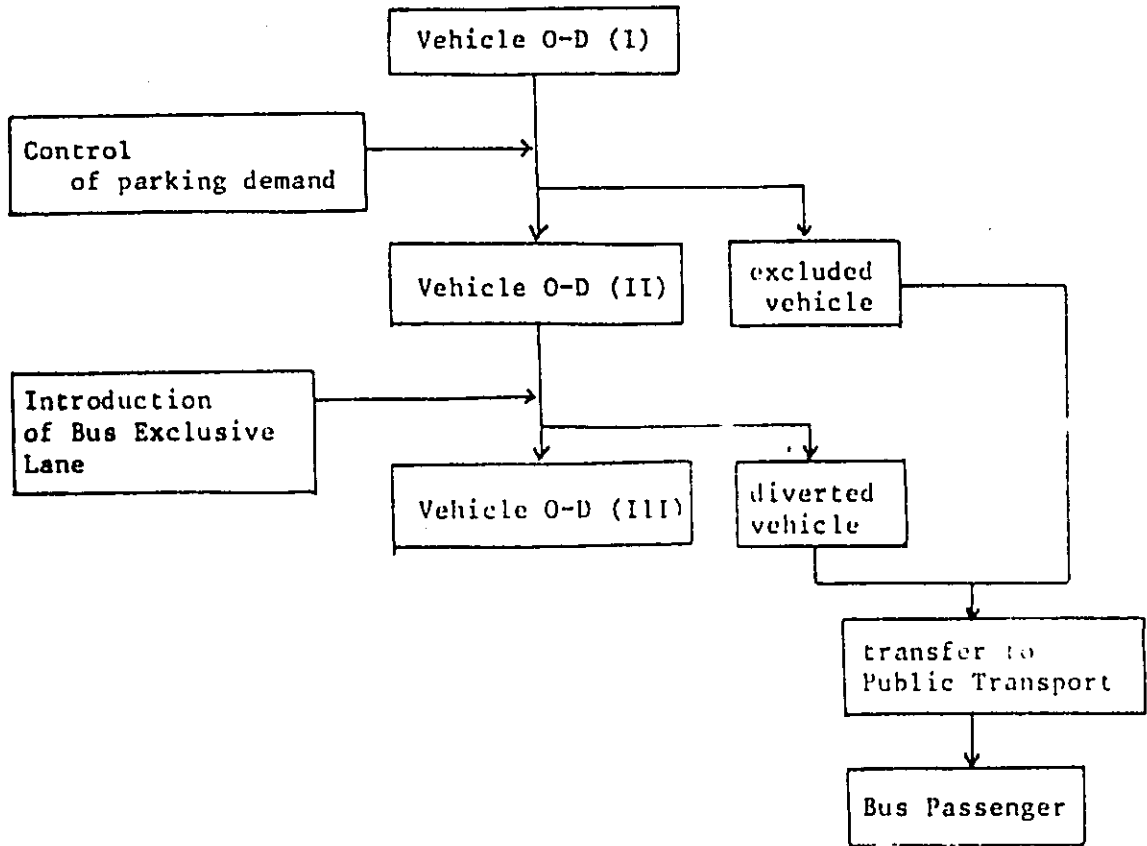

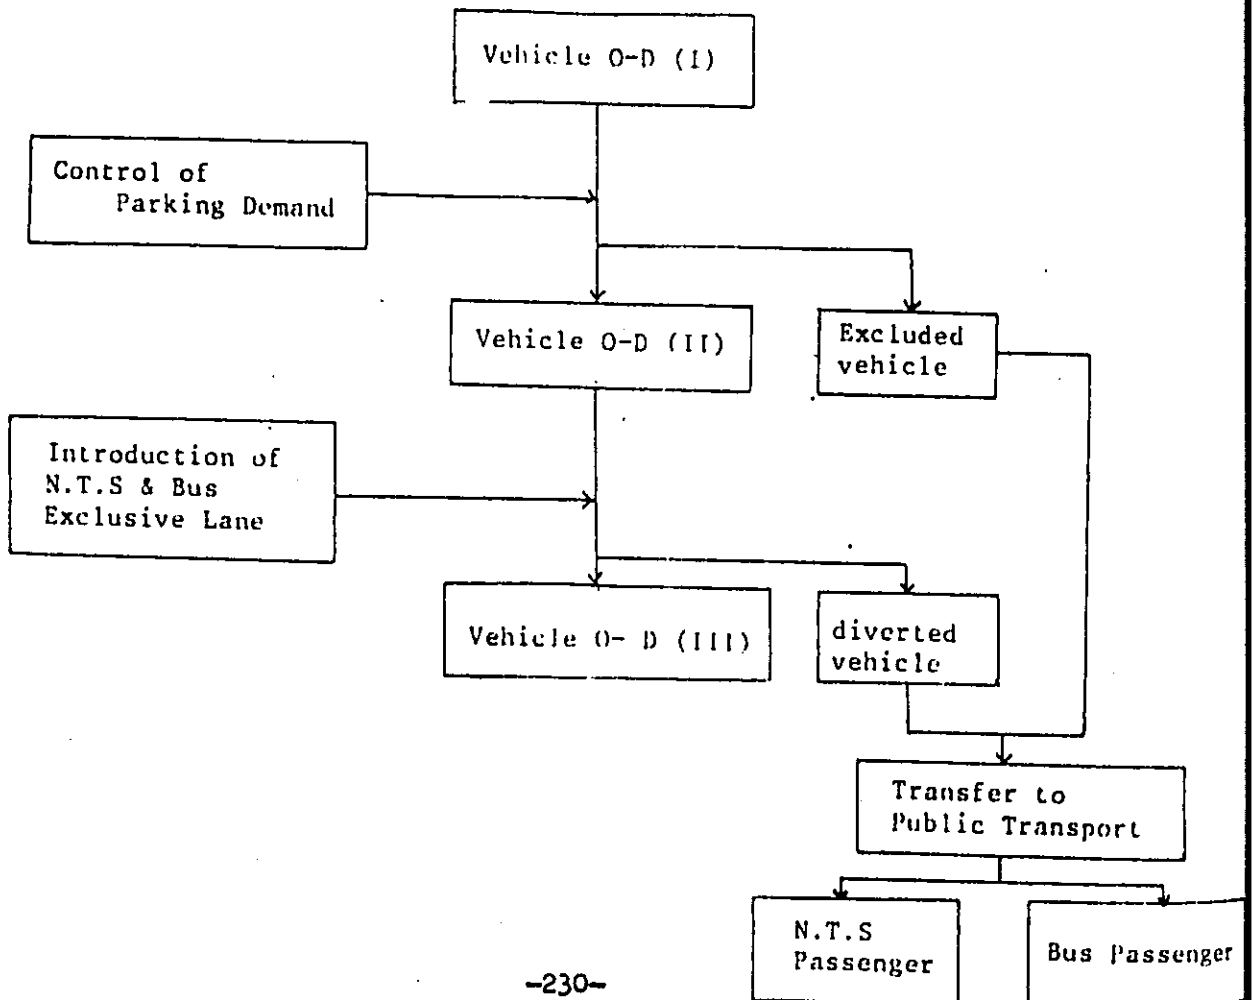

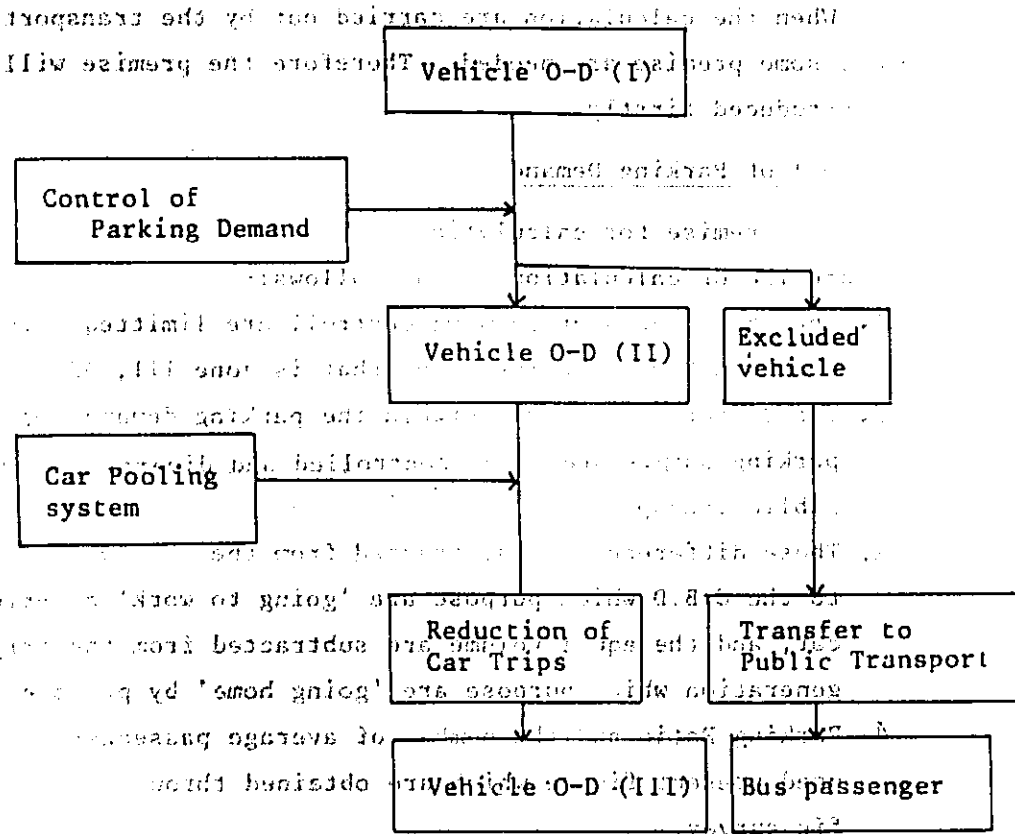

Fig. : 7.2 Alternative Plan - C

**Fig. : 7.3 Alternative Plan - D**

The way of the calculation will be explained in the next page.

There are no restrictions concerning the number of passengers in a car. It is very difficult to estimate the future number of passengers in a car. The average number of passengers is 1.4 in each car.

see

7.2

The way of the calculation

When the calculation are carried out by the transport plan, some premise are needed. Therefore the premise will be introduced firstly.

7.2.1

Controll of Parking Demand

(1) The premise for calculation

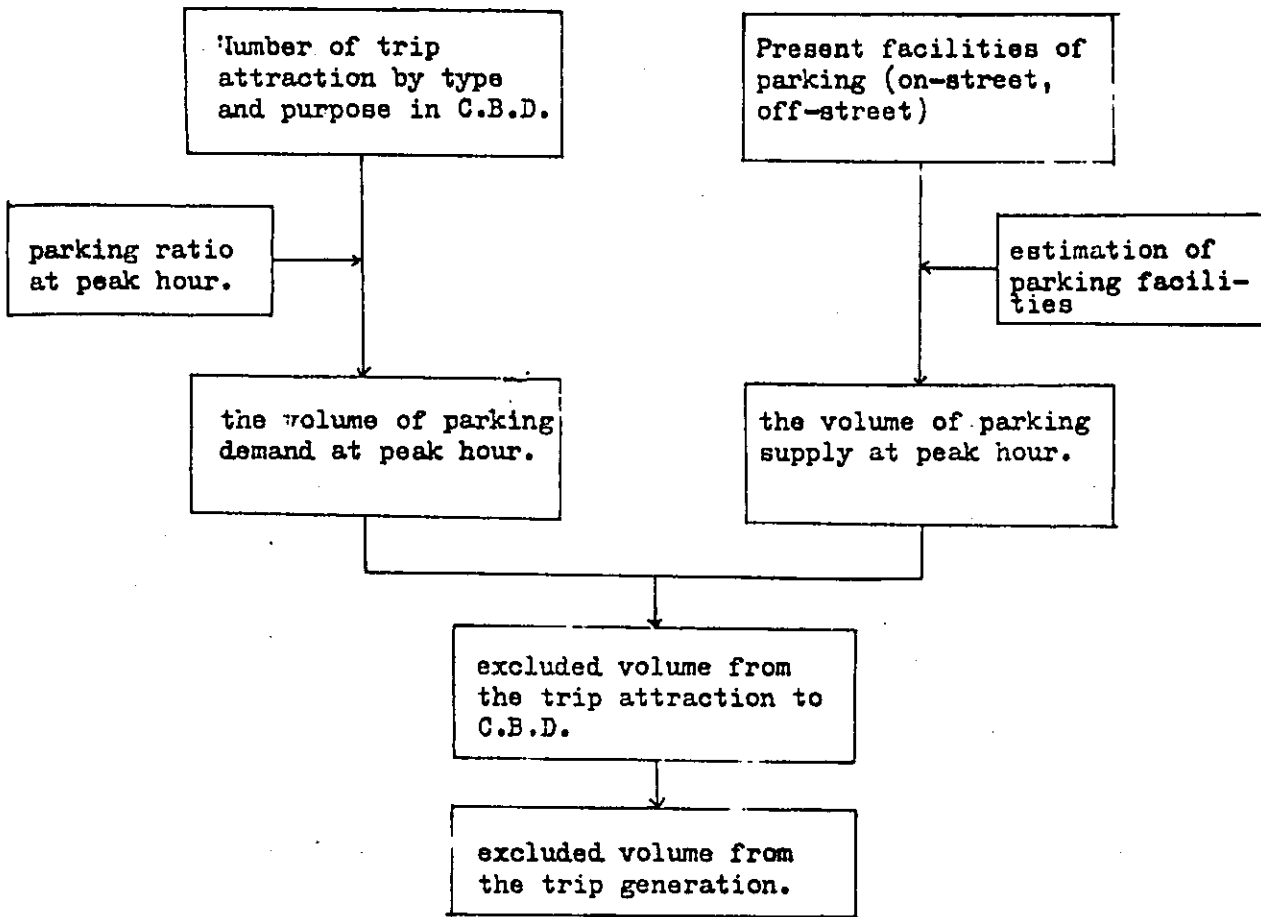

The premise of calculation are as follows:-

1. The object area of parking controll are limited only within C.B.D in George Town (that is zone 111, 121, 131).
2. The difference volume between the parking demand and the parking supply are to be controlled and diverted to the public transport.
3. These difference are subtracted from the trip attraction to the C.B.D which purpose are 'going to work' by private car, and the equal volume are subtracted from the trip generation which purpose are 'going home' by private car.
4. Parking Ratio and the number of average passenger are used present figure which are obtained through the traffic survey.
5. There are no restriction concerning to motor-cycle because it is very difficult to estimate the future parking supply.
6. The average number of passengers is 1.4 in each private car.

(2) The result of calculation.

The calculations are executed as the following flow chart.

Fig. : 7.4 Flow chart of parking control.

The volume of parking demand at peak hour is calculated by multiplying the volume of trip attraction with the parking ratio. The parking ratio at peak hour are as follows:-

Table 7.1 The parking ratio at peak hour (10 - 12A.M.)

Car	To work	0.42
	On business	0.14
	Private	0.07
	Home	0.04
Lorry		0.14
Taxi		0.0
Bus		0.0

The parking demand at peak hours are as follows:-

Table 7.2 Parking demand at Peak Hour in C.B.D.  
(Unit : trip on!)

	1979	1985	2000
Car To Work	12440	15010	24410
On Business	1330	2320	3930
Private	1290	1690	3030
Home	540	630	930
Lorry	1300	1600	3300
Total	17450 (100)	21300 (122)	35650 (204)

Fig. : 7.5 Parking demand at peak hour.

The volume of parking supply are estimated by our parking survey as follows:-

Table 7.3 The volume of parking supply  
(Unit:vehicles)

	1979	1985	2000
On-Street	14133	11500	10000
Off-Street	3491	6500	11000
Total	17624	18000	21000

From Table 7.2 and Table 7.3 , the excluded volume due to the shortage of parking supply are calculated as follows;

Table 7.4 The excluded volume  
(Unit:1000 trip end)

	1979	1985	2000
demand volume	17.5	18.0	21.0
supply volume	17.6	21.3	35.7
difference	+0.1	-3.3	-14.7
excluded volume	-	-6.7	-29.3

Diverted volume to Public Transport

People who lived in urban area always chose their own mode among their available transport according to their judgement. The judgement are consist of varoius factors, but generally the factors are represented by concept of distance from origin place to destination. The distance includes, of course, actual distance, time distance and economic distance which includes the travel fare.

At 'Urban Transport Policy and Planning Study for Metropolitan Kuala Lumpur', the modal-choice model are applied the diversion curve and the factors of modal-choice are chosed time difference between alternative transport.

In Penang State, there are no modal-choice data, then the above-mentioned data in Kuala Lumpur are made use of the examination of diversion from traffic volume to public transport.

In above mentioned study in Kuala Lumpur, some diversion curve are verified by house-hold group and trip purpose. Among of them the representative curves are as follows;

Fig. : 7.6 Diversion Curve in K.L.

From these curve, following diversion ratio are obtained.

Table 7.5 Diversion ratio between car and public Transport

reduction of time difference (min)	increasing ratio of public transport usage (%)
5	10
10	18
15	24

(One Car Households - Home based Work)

Table 7.6 Diversion ratio between M/C and public transport.

reduction of time difference (min)	increasing ratio of public transport usage (%)
5	8
10	19
15	25

(Motorcycle Households - Home-based Work)

It is not accurate way to use the modal-choice modal of other city in severe examination, but it is equal to examine

rough diversion from vehicle to public transport.  
 (1) The premise for calculation are as follows:  
 (2) This calculation are conducted in case of the execution of bus exclusive lane and the introduction of New Transport System.

Following premise are decided to calculate.

1. The object area for diversion are limited those area which are directly related to the new transport plan.

2. The object trip for diversion are only 'going to work' which made by private car and motor-cycle. And after calculation of diversion finished, the equal volume which are diverted to public transport from 'going to work' are subtracted from trip purpose 'going home'.

3. The schedule speed are determined as follows;

- Bus : On exclusive lane 25 km/h.
- On other lane (urbanized area) 15 km/h.
- On other lane 20 km/h.
- 30 km/h.

N.T.S.

(minutes)

difference

(2) The results of calculation

The volume of diversion from car and M/C to public transport are shown at followed Table.

Table 7.7 The volume of diversion by transport plans.  
(Unit:1000 trips)

Year		In Penang Island		In Province Wellesley	
		Car	M/C	Car	M/C
1985  Caused by Bus Exclusive Lane	internal trip A	221.9	273.7	71.8	151.6
	object trip purpose for diversion B	124.9	156.0	40.2	86.4
	object trip related to the object area C	24.2	28.1	5.8	11.5
	Volume of diversion D	2.3	3.6	0.5	1.2
	ratio of diversion (D/C x 100)	9.5%	12.8%	8.6%	10.4%
2000  Caused by Bus Exclusive Lane	internal trip A	424.0	241.8	215.1	193.8
	object trip purpose for diversion B	237.4	137.8	120.5	110.5
	object trip related to the object area C	37.2	21.6	16.7	14.4
	volume of diversion D	3.5	3.6	1.7	2.1
	ratio of diversion (D/C x 100)	9.4%	16.7%	10.2%	14.6%

		In Penang Island		In Province Wellesley	
		Car	M/C	Car	M/C
2000	internal trip A	424.0	241.8	-	-
	object trip purpose for diversion B	237.4	137.8	-	-
N.T.S	object trip related to the object area C	75.0	56.9	-	-
	volume of diversion D	12.9	9.1	-	-
	ratio of diversion (D/C x 100)	17.2%	24.1%	-	-

NOTE : Object trip purpose for diversion (B) :

The traffic volume, the purpose of which is 'going to work' and 'going home'.

Object trip related to the object area (C) :

The traffic volume which generates or attracts from/to the object area.

Object area

The area in which the new transport plan is introduced.

These volume of diversion are not so large, that is, 2800 cars and 4800 M/C in 1985, 5200 cars and 5700 M/C in 2000 and after introduction of N.T.S, these figures are 12900 cars and 9100 motor-cycle.

Comparing with the total trips, these volume of diversion are only 1.2% of vehicles and 1.9% of motor-cycles even if after introduction of N.T.S.

It is because the object trip and limited by trip purpose and by area.

### 7.2.3

#### Execution of Car Pooling system

Car Pooling System is divided for the purpose of preventing from the traffic congestion which are caused by private car entering to C.B.D.

According to the rule, the number of passenger in each car are enforced to be more effective, that is, to be full of capacity. As a result of the restriction, the number of car which passengers are a few will be on the decrease and the traffic volume also will decrease.

(1) The premise for calculation

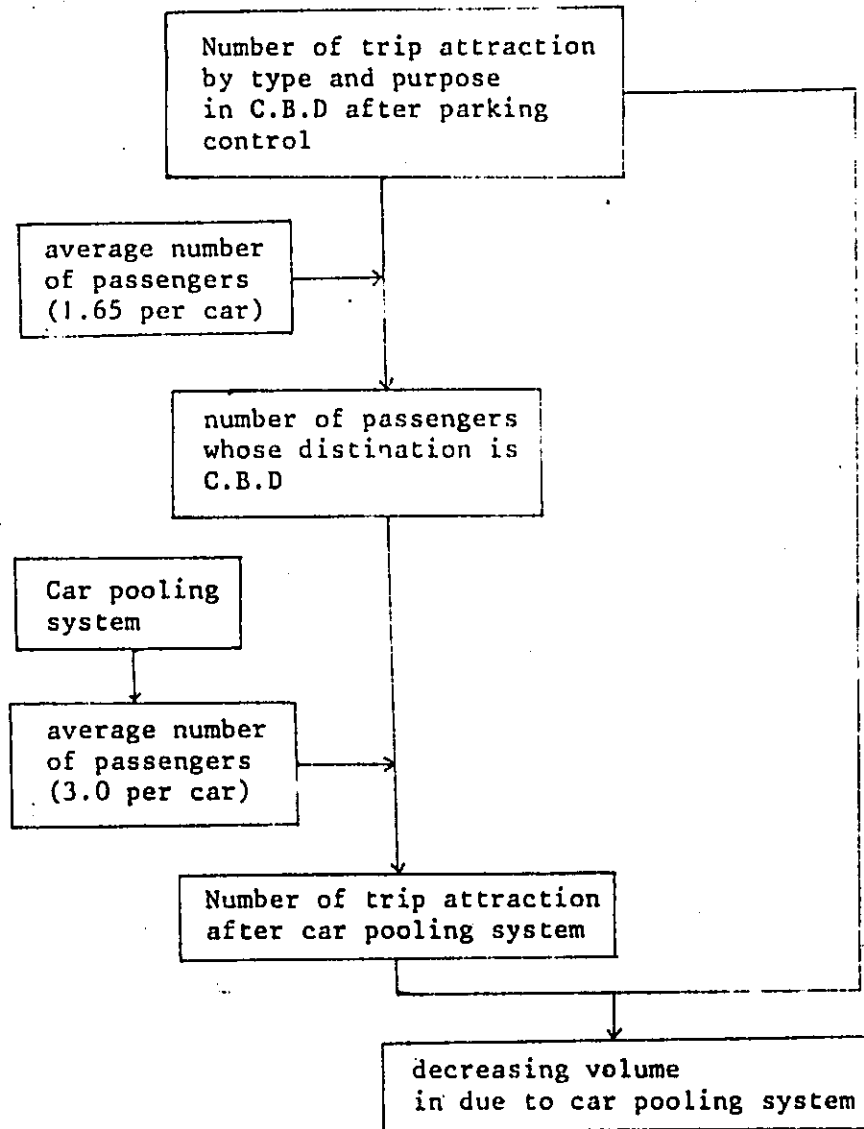

The premise are as follows;

1. The object area of car pooling system are limited only within C.B.D in George Town.
2. The object trips are those which destination are C.B.D and also trip purpose is 'going to work' and 'private'.
3. Average number of passenger in each private car are enforced to be average 3.0 person includes the driver from 1.65 persons, therefore the decreasing ratio of traffic volume is  $0.45 (3.0-1.65/3.0)$ .
4. The equal volume with the decreasing number of intering volume into the C.B.D are subtracted from coming out volume from C.B.D.

(2) The results of calculation

The calculation are conducted as following flow-chart in 2000 year.

Fig. 7.9 Flow chart of calculation

The number of trip attraction in C.B.D after parking control are as follows;

Table 7.8 Number of trip attraction in C.B.D (Unit : 1000 trip ends)

Car	To work	43.4
	On Business	28.0
	Private	43.3
	Home	24.4
Lorry		23.6
Taxi		7.5
Bus		5.9
Sub-total		176.1
M/C		95.5

From this table, the number of passengers whose trip purpose are 'going to work' 'private' are as 143100 persons. (86700 cars x 1.65 persons).

After excuting of car pooling system, following number of cars will be decreased.

Table 7.9 Decreasing volume due to car pooling system.

	number of trip attraction	number of passengers	average number of passengers
before car pooling system	86.7	141.3	1.65
after car pooling system	47.7	143.1	3.0
decreasing volume on one way direction	39.0		
decreasing volume on both way	78.0		

As a result of these restriction, number of trip attraction in C.B.D are decreased as followed figure.

Fig. 7.10 The effect of car pooling system in C.B.D.

7.3

Estimation of future traffic demand by transport plan.

7.3.1

Number of total trips by transport plan.

Estimation by transport plan are conducted according to the above-mentioned premise. Number of total trip (p.c.u) are changed as follows;

Fig. 7.11 , Number of total trip by transport plan.

## 7.3.2

The comparizon of transport plan in George Town

(1) Number of trips related to George Town.

Number of trips by transport plans are as follows:-

Table 7.10 The comparizon by transport plan in George Town.

(Unit:1000 trips)

		Vehicle			M/C		
		internal	external	total	internal	external	total
1985	Plan A	180.5	92.9	273.4	185.4	59.3	244.7
	Plan B	173.8 (-6.7)	90.6 (-2.3)	264.4 (-9.0)	182.5 (-2.9)	58.7 (-0.6)	241.2 (-3.5)
2000	Plan A	277.0	231.5	508.5	148.1	57.4	205.5
	Plan B	255.7 (-21.3)	219.9 (-11.6)	475.6 (-32.9)	145.2 (-0.8)	56.6 (-3.7)	201.8
	Plan C	252.8 (-24.2)	216.2 (-15.3)	469.0 (-39.5)	142.7 (-5.4)	54.1 (-3.3)	196.7 (-8.7)
	Plan D	208.3 (-68.7)	192.8 (-38.7)	401.1 (-107.4)	145.2 (-2.9)	56.6 (-0.8)	201.8 (-3.7)

Fig. 7.16 The comparizon of number of trips related to George Town.

Note : above figures include internal trip and external trip of George Town.

(2) Number of trip generation and attraction in C.B.D of George Town.

Number of trip generation and attraction in C.B.D area (zone 111, 121, 131) by transport plan are as follows;

Table 7.11 The comparizon of trip generation and attraction in C.B.D

(Unit:1000 trip ends)

		Vehicle	(Car)	M/C
1985	Plan A	223.1	(186.7)	227.8
	Plan B	213.5 (-9.6)	177.1 (-9.6)	225.1 (-2.7)
2000	Plan A	381.5	(307.7)	191.0
	Plan B	345.4 (-36.1)	271.6 (-36.1)	188.3 (-2.7)
	Plan C	341.2 (-40.3)	267.4 (-40.3)	185.2 (-5.8)
	Plan D	258.7 (-122.8)	184.9 (-122.8)	188.3 (-2.7)

(Vehicles) (Unit:1000 trip ends)

8.

Estimation of the future traffic demand on road network.

The road networks which are intended for traffic assignment are as follows:-

1979	Present network
1985	On going On going & Proposed
2000	On going & Proposal Ultimated Ultimated

The content of these road network are as follows:-

On going      The present road network to which is added the linkage plan, the dispersal plan, the federal route plan and some improvement on existing road.

On going & Proposed      The road network where our proposed new road plans (e.g. project 1, 2, 3 and 4) are added to 'On going'.

Ultimate      The road network where some road plans and plans to widen the roads are added to 'On going & Proposed'.

The simulation for traffic assignment are conducted according to following table:-

Table 8-1      Simulation for traffic assignment

O-D	Network	On going	On going & Proposed	Ultimate
1985	Plan A	0		
	Plan B		0	
2000	Plan A			
	Plan B		0	0
	Plan C			0
	Plan D			0

Regarding the toll charged, the following are taken in to consideration. In America, the toll rates which fall within the range of M\$00.5 to M\$00.8 per mile is common. At the Slim River toll-gate, a toll of M\$1.00 is imposed for the use of the new 18 mile section on Federal Route 1. Toll collection is only along one-way, hence, the charge is for 36 miles at a rate of M\$0.028 per mile.

In the case of the Alor Star - Butterworth project, toll-gates are located at intervals of about 15 miles and the toll is expected to be M\$0.50 per passenger car trip giving the rate of M\$0.033 per mile. The toll rates on Federal Route 1 in this study area is M\$0.033 per mile. On the other hand, the decision regarding the toll for the Linkage is influenced by the fare for the ferry, i.e. M\$1.75 for one way.

This fare is converted in to time by dividing the fare by the time value. The time value used are as follows:-

Table 8-2 Time value

	1979	1985	2000
passenger car	3.70 M/Hour	4.50 M/Hour	7.30 M/Hour
motor-cycle	1.30 M/Hour	1.60 M/Hour	2.60 M/Hour

Assignment for the road network without Ferry

The traffic volume on the strait are obtained from traffic assignment as follows:-

Table 9.1 Traffic Volume on the strait  
(Unit:1000 trip)

O-D	NETWORK	Ferry			Linkage		
		P.C.U (ex. m/c)	M/C	P.C.U	P.C.U (ex. m/c)	M/C	P.C.U
1979	Present	12.8	13.0	19.3	-	-	-
1985	- Plan A On going	2.7	4.6	5.5	20.8	8.4	25.0
	- Plan B On going & Proposed	2.1	6.5	5.4	21.2	7.5	25.0
2000	- Plan B On going & Proposed	17.3	6.5	20.6	49.7	8.7	54.1
	Ultimate	14.6	6.2	17.7	52.4	8.9	56.9
	- Plan C Ultimate	14.9	6.2	18.0	52.1	8.9	56.6
	-Plan D Ultimate	13.0	6.2	16.1	51.2	8.9	55.7

For the purpose of measuring the effect of the ferry, the assignment are conducted on the road network without ferry (2000 - plan B, Ultimate)

Table 9.2

The Comparison between With Ferry and Without Ferry

(Unit: 1000 p.c.u)

		With Ferry	Without Ferry
Inner Cordon	P.C.U. (ex m/c)	247.8	262.4
	M/C	67.4	72.2
	P.C.U.	281.6	298.5
Center Cordon	P.C.U. (ex m/c)	357.9	372.5
	M/C	83.9	90.1
	P.C.U.	400.0	417.6

Therefore, if only the ferry service for vehicles (ex m/c) are stopped, the traffic volume will increase as follows:

Table 9.3

Traffic Volume Without Ferry for Vehicles (ex m/c)

(Unit: 1000 p.c.u.)

Inner Cordon	P.C.U. (ex m/c)	262.4
	M/C	67.4
	P.C.U.	296.1
Center Cordon	P.C.U. (ex m/c)	372.5
	M/C	83.9
	P.C.U.	414.5

From this the traffic volume on the inner cordon line increase 12200 in traffic volume and on the center cordon line 14200 in traffic volume.

As a results of above-mentioned situation, the degree of congestion on each line are increased as follows;

Fig. 9.2 The comparison of traffic volume.

2000 - Plan B
Ultimate
P.C.U (ex, M/C)

2000 - Plan B
Ultimate (without ferry)
P.C.U. (ex m/o)

2000 - Hlan B.
Ultimate
Motocycles

2000 - Plan B
Ultimate (without ferry)
Motorcycles
