## I. OBJECTIVE AND METHODOLOGY APPLIED

### 1.1 Objective

The objective of this ANNEX (D) is to present the methodology, assumptions and procedures used in making the power demand forecast by consumer sectors which were carried out by HMG and referred in the Clause 3.3 of the Main Report. The JICA Team's view on this study is provided at the end of this ANNEX (D).

### 1.2 Methodology Applied

For the purpose of the power demand forecast, the consumers were divided into following five sectors.

- (i) Industrial
- (ii) Commercial
- (iii) Irrigation
- (iv) Domestic
- (v) Street lighting, water supply and others

The sectoral power demand forecast was based on past data on the power demand, economic growths and potential projects projected in the 6th and 7th Five Year Plans which cover the periods from 1980/71 to 1984/85 and from 1985/86 to 1989/90, respectively. Among the projected economic growth, those having a significant influence on the power demand forecast are given below.

	Item	6th 7th Plan Plan	Sector to be applied
	Growth in non-agricul- tural GDP (%/year)	5.6 7.0	Industrial
(11)	Growth in tourist arrivals (%/year)	15 15	Commercial
(111)	Newly irrigated area (ha) (Groundwater & lift)	23,750 86,000	Irrigation
(iv)	Growth in domestic consumers (%/year)	8.2 8.2	Domestic, street lighting & others

### Economic Growth Projected in 6th and 7th Plans

In order to forecast the future energy requirement by the said consumer category, the following projection methods were used and the results were compared in the sectors where two different methods were applied.

4. A. A. A. A. A.

	Method	Sector applied	-

D

### II. SECTORAL POWER DEMAND FORECAST

### 2.1 Industrial Demand

Energy sales to the industrial sector inclusive of those in the Kulekhani project increased at an annual rate of 25% for the period from 1970/71 to 1974/75 and 24% for the period from 1975/76 to 1979/80 as shown in Table-D.1. The industrial demand was firstly estimated by means of the macro-economic method in which the recorded relationship between the electricity sales to the sector and the non-agricultural GDP was used. Besides the macro-economic method, an alternative approach was made by relating the amount of investment to the total energy requirement for the industrial projects which are planned in the 6th and 7th Plans, and the results by these methods were compared.

### (1) Macro-economic method

As stated, the industrial power demand was firstly examined based on the records of electricity sales to the industrial sector and of non-agricultural GDP, considering a relationship between these two indicators.

Based on the recorded data of the non-agricultural GDP and the energy consumption in the industrial sector, which are shown in Table-D.1 and Table-D.2 respectively, a logarithmic model representing the relation between these indicators was established as follows.

$$\operatorname{Sn} = \operatorname{So} \cdot \left(\frac{\operatorname{Gn}}{\operatorname{Go}}\right)^a = \operatorname{So} \cdot \left(\frac{\operatorname{Gn}}{\operatorname{Go}}\right)^3$$

where, So : electricity sales in the base year
Gn, Go : non-agricultural GDP in year n and base year, and
a : elasticity value which is estimated to be 3.0
based on the historical data

The annual growth rate of the non-agricultural GDP was projected at 5.6% in the Sixth Plan (from 1980/81 to 1984/85) and 7.0% in the Seventh Plan (from 1985/86 to 1989/90) respectively. Applying the annual growth rates of non-agricultural GDP projected in the Sixth and Seventh Plans on the established logarithmic model, the annual growth rates of energy consumption in the industrial sector were estimated as shown below:

	Projected growth	Estimated consumption
Period	rate of non-agri- cultural GDP (%)	growth rate in industrial sector (%)
1980/81 - 1984/85	5.6	17.8
1985/86 - 1989/90	7.0	22.5

From the above figures, the energy requirement in the industrial sector for the period were calculated as shown in Table-D.3, assuming that the energy loss ratio to the energy consumption will gradually decrease from 40% in 1980/81 to 30% in 1989/90. The results of the analysis indicated a rapid growth of industrial energy requirement from around 60 GWh in 1979/80 to 488.9 GWh in 1989/90.

(2) Method by relating energy requirement to total investment

In the 6th and 7th Plans, a number of industrial projects were planned to be implemented as shown in Table-D.4. The start-up date, required energy and investment cost of the respective project are mentioned in the Table. An alternative approach of relating the energy requirement to the total investment was tried to make the demand forecast based on the identified potential project. This approach was made for confirmation of the forecast made by the macro-economic method.

In the analysis, the sector was sub-divided into industrial, construction and transportation sectors.

(i) New industries in the 6th Plan

The average power requirement per Rs Billion of the investment for the industrial projects likely to be developed in the 6th Plan was estimated to be 12.5 MW/Rs billion as shown in Table-D.5. According to HMG's plan, the total investment cost in the industrial sector in the 6th Plan is expected to amount to around Rs 1.2 billion. Accordingly, the power and energy requirements for the new industrial projects were estimated to reach 15 MW and 66 GWh in 1984/85 assuming an energy loss ratio of 20%, load factor of 60% and capacity utilization ratio of 70%.

(11) New industries in the 7th Plan

In the 7th Five Year Plan, certain industrial projects such as steel industry and nitrogen fertilizer projects will be more energy intensive, with higher ratio of energy requirement to investment. Hence, a ratio of 20 MW/Rs billion was assumed for the prediction of the power requirement. The anticipated total investment in the industrial sector for the Plan is around Rs 2.0 billion, around 75% higher than that in the 6th Plan. Then, the power and energy requirement in 1989/90 for the 7th Plan were estimated to be 40 MW and 218 GWh assuming a energy loss ratio of 20%, load factor of 65% and capacity utilization ratio of 80%.

(iii) Energy requirements for construction and transportation sectors The Kulekhani hydroelectric project consumed 10 GWh in 1989/90 during its construction stage. In near future, some hydroelectric projects such as Kulekhani No.2, Marsyangdi are planned for implementation. Thus, the electricity consumption in the construction sector was assumed to reach 20 GWh in 1984/1985 and 40 GWh in 1989/90, by taking into account that these projects will be realized.

1.2 GWh was sold to the transportation sector which comprises the Kathmandu-Hetauda ropeway and the trolly-bus system. In the 6th Plan, these facilities are to be extended and upgraded to meet the increasing demand. In addition, the new ropeway lines in other regions than the Central Nepal, such as Bhojpur-Dankhuta (Eastern region), Jomsom-Baglung (Western) and Surkhet-Jumla (Far western) are now in the feasibility study stage and are expected to be constructed in the course of the 7th Plan. Taking into consideration these plans, the electricity consumption in the transportation sector was estimated to be 2.4 GWh in 1984/85 and 4.8 GWh in 1989/90.

(3) Comparison of two methods for industrial demand forecast

The energy requirement estimated by relating the energy requirement to the investment are summarized in Table-D.6. The total energy requirement in the industrial sector is derived to be 198 GWh in 1984/85 and 463 GWh in 1989/90. These figures concurred approximately with those

D - 5

derived by the Macro-economic method shown in Table-D.3.

### 2.2 Commercial Demand

The large consumers in the commercial sector consist mostly of hotels. And it was recognized from the historical data on the growth of energy consumption in the commercial sector that there is a high correlation between the number of toursit arrivals and the energy consumption in the sector as seen on Fig.-D.1. As such, the demand forecast in the commercial sector was made based on the growth of tourist arrivals projected in the 6th and 7th Plans.

In the 6th and 7th Plans, it was projected that the recorded mean growth rate of 15% during the past 10 years will be maintained over the next 10 years. Based on the relation of a direct proportion between the tourist arrivals and energy consumption in the commercial sector, the demand forecast in the commercial sector was made as shown in Table-D.7. In the forecast, the energy loss rate was assumed to reduce from 39% in 1980/81 to 30% in 1989/90.

As seen in the Table, the energy requirement in the commercial sector was forecast to reach 42.7 GWh in 1984/85 and 82 GWh in 1989/90.

#### 2.3 Irrigation Demand

In 1979/80, the irrigation sector consumed only 2 GWh. The small consumption was due to the poor progress of irrigation projects planned to be implemented in the previous Plan. Consequently, it is stressed in the 6th Plan to strongly promote the implementation of agricultural development. The irrigation projects both on-going and likely to be implemented in the 6th and 7th Plan which have a significance in electricity consumption, namely groundwater or lift scheme, are listed in Table-D.8.

The energy requirement for the operation of these irrigation projects were also estimated as shown in the Table based on the power requirement and implementation schedule presented in each feasibility study report, a load factor of 50%, energy loss ratio of 20% and coincidence factor of 35%. As seen in the Table, the energy requirement in the irrigation sector is anticipated to reach 183.4 GWh in 1989/90.

### 2.4 Domestic Demand

Electricity sales to the domestic sector increased at an annual average rate of 13% for the period between 1970/71 and 1979/80 and 15% for the period between 1970/71 and 1978/79 as shown in Table-D.9. The number of domestic consumers has grown steadily at a rate of 10.2% for the period between 1970/71 and 1979/80. The average consumption per consumer for the period from 1975/76 to 1978/79 was estimated to be around 800 kWh/consumer, while it lowered in 1979/80 to 713 kWh/consumer due to the severe influence of load shedding. The demand forecast in the domestic sector were made by means of the macro-economic method and the method of projecting the number of consumers and the consumer's average consumption based on the historical data.

### (1) Macro-economic method

Since the major part of the domestic consumers are in urban areas or in their neighbourhood, electricity sales to the sector are considered to have a correlation with non-agricultural GDP to a considerable extent.

The comparison of the respective evolution of domestic sales and non-agricultural GDP over the period 1970/71 to 1978/79 resulted in the following logarithmic relationship.

> Sales = 2.48 (N.A.GDP)<sup>1.75</sup> (GWh)

where, N.A. GDP : Non-agricultural GDP in Rs. billion at 1974/75 price.

Applying the growth of non-agricultural GDP projected in the 6th and 7th Plans, the energy sales to the domestic sector was projected as shown in Table-D.11. As seen in the Table, the projected energy requirement in the domestic sector through the macro-economic method was 186.3 GWh in 1984/85 and 325.0 GWh in 1989/90.

### (2) Consumer's average consumption method

The domestic demand was forecast by assuming that the number of domestic consumers will increase at an average growth rate of 8.2% and that the average consumption of 800 kWh/consumer/year which has been stagnant due to the load shedding will increase at a yearly increment of 20 kWh/consumer/year.

Assuming the gradual decrease of energy loss ratio from the current 40% to 30% in 1989/90, the energy requirement in the domestic sector is estimated to be 189 GWh in 1984/85 and 300 GWh in 1989/90 as shown in Table-D.10. These figures well coincide with those estimated by the macro-economic method.

2.5 Street Lighting, Water Supply and Other Requirements

A high correlation was observed between the sales of electricity for street lighting and the number of consumers in the domestic sector as shown in Table-D.9. Consumption for street lighting amounts to 20 kWh/ consumer in average. This relationship was applied to the projected number of consumers to forecast the future requirements for street lighting.

It is reasonable to assume that water supply requirements will expand with the number of domestic consumers. Presently, the consumption for water supply is about 10 kWh/consumer, which was applied to the projected number of consumers to forecast the future requirements for water supply.

Self consumption of the utilities has been 1.5% of the energy requirements in average over the last five years. A similar figure was used for the future requirements.

Exports of electricity to India from the CNPS have been 6 GWh in average over the last five years. The forecast of the future requirement for exports was made assuming these will remain constant in the future. Detailed calculation of the energy requirements for all the above sectors appears in Table-D.12. As seen in the Table, the energy requirement for the above was estimated to reach 32.2 GWh in 1989/90.

### III. THE JICA TEAM'S VIEW FOR SECTORAL DEMAND FORECAST

The summary of the sectoral demand forecast made by HMG is given in Table-D.13. It is seen in the Table that the total energy requirement in Nepal will reach around 500 GWh in 1984/85 and 1,000 GWh in 1989/90.

The JICA Team's view on this forecast is as follows.

(1)

The sectoral demand forecast is considered as a logical approach to estimate the future energy requirement, but it also relies on the assumption of the economic indicators concerning the future growths in non-agricultural GDP, tourist arrival, domestic consumers, etc. In view of the recent international economic situation, it is difficult to judge the reliability of the indicators assumed in this forecast, but, as a whole, the assumptions are not so optimistic and the estimated requirement of about 1,000 GWh in 1989/90 is not considered overestimated. However, as for the share of the requirement for each sector, it is judged that the requirement for the industrial sector is overestimated, while that for the domestic sector is underestimated, eventually offsetting the overestimation.

(2) The energy requirement in the industrial sector was forecasted by two methods, i.e. the macro-economic method based on the growth of non-agricultural GDP and the method by relating the requirement to the investment for the potential industrial projects planned in the 6th and 7th Plans. The requirement estimated by these two methods indicated an approximate concurrence, being 450 to 500 GWh. However, this amount takes more than 45% in the share of the total energy requirement and this seems to be excessive. Among the potential industrial projects and the required investments in the 6th and 7th Plans which are shown in Table-D.4, the promising projects to be implemented with realistic background would be the Hetauda Cement Plan and the Magnesite Industry in the 6th Plan, and the Nitrogen Fertilizers Plant and Udaypur Cement Plant in the 7th Plan. Then, even if all of these projects are implemented, the total investment would be around 90% of that projected in the period of the 6th and 7th Plan or until 1989/90. Further, there is still a risk of deferment in implementation due to the

prevailing economic recession, resulting in less investment during the period of the Plan.

Therefore, in general, it seems that so far as the approach by relating the energy requirement to the investment is concerned, it would indicate less future energy demand and that this would happen more likely than that estimated by the macro-economic method.

- (3) The energy requirement in the domestic sector was also forecasted by two methods, i.e. the macro-economic method and the method by assuming that the number of domestic consumers will increase at the average growth rate of 8.2% and that the average consumption rate of 800 kWh/consumer/year will gradually increase at a yearly increment of 20 kWh/consumer/year based on the past records of energy consumption. This projection is judged to be rather conservative.
  - In the domestic sector, it is generally recognized that the demand has been suppressed due to the load shedding and suspension of new consumers' applications and that it will rapidly grow once the power generating capacity and distribution system are improved. This tendency is endorsed by the fact that the power demand in CNPS jumped up from 35 MW to 56 MW immediately after the completion of the Kulekhani No.1 Project and reinforcement of the Kathmandu distribution system. HMG plans to reinforce the power supply capacity by a series of hydropower development such as the Devighat Project, Kulekhani No.2 Project and Marsyangdi Project, etc. and also to expand the power transmission system to the eastern and western regions. Besides, further improvement of the Kathmandu distribution system is planned. The electrification plan in the rural area is also to be materialized in the near future.

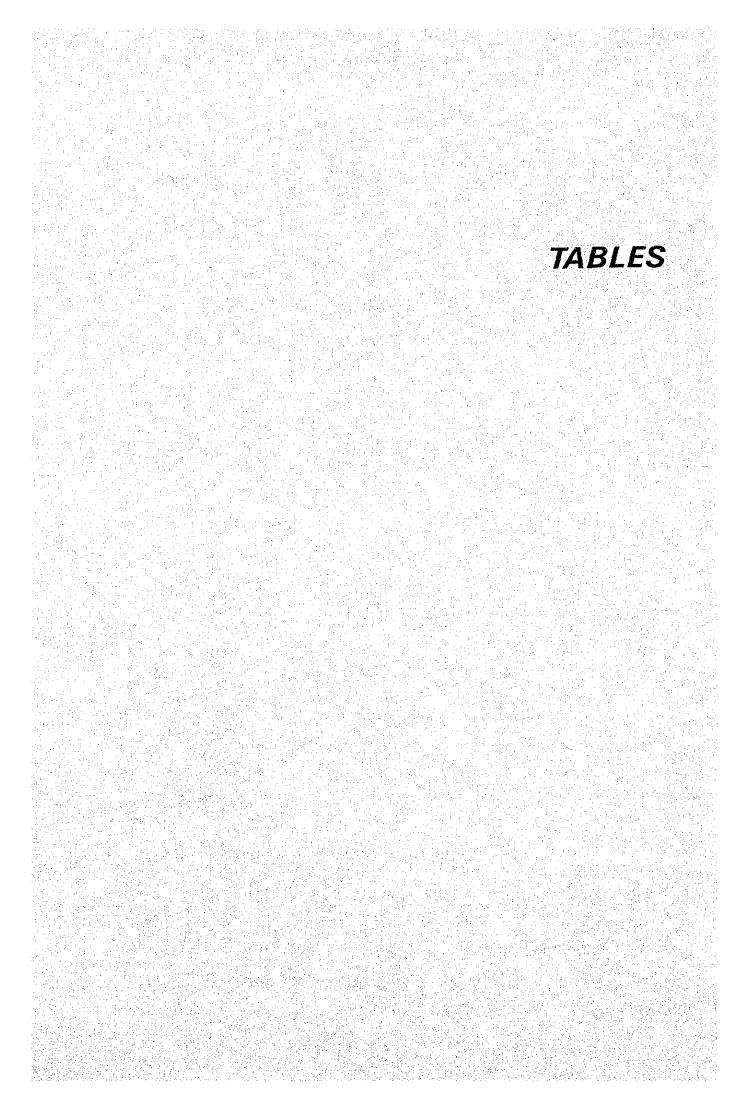

Such being the situation and also because of the fact that the growth rate of the number of domestic consumers for the past 10 years until 1979/80 was 10.2% on an average, the number of consumers is anticipated to increase at a growth rate higher than 8.2%. The consumption rate of 800 kWh/consumer/year is also anticipated to increase at a yearly increment of more than 20 kWh/consumer/year.

With the above in view, it is considered that the requirement in the domestic sector estimated by HMG is rather moderate and that the share of the requirement for this sector would be more or less the same as that for the industrial sector.
