| Microscopic Observations | The rock is composed chiefly of altered matic minerals and plagicclase ophitically intergrown. Matic minerals are completely altered to an aggregate of epidote, carbonate, and chlorite. Plagicclase is partly altered to saussurite. Quartz clots are also present. | Abundant angular to subangular quartz grains are accompanied by large and small unoriented flakes of attered biotite or chlorite and muscovite. Feldspars are subordinate. Matrix is cryptocrystalline quartz, chlorite, and sericite. | Angular to subangular grains of quartz and feldspar are set in a metric of orprocrystalline calcine, sericine, and chlorife. Opaques are present in considerable amounts. | Angular to subangular grains of quartz are cemented by a calcarrous matrix with cryptocrystalline quartz, chlorite, and muscovite. Euhedral opaques slightly corroded from surface are present in considerable amounts. | Fragments of subangular quartz are dispersed in a matrix consisting of cryptocrystalline quartz, chlorite, and sericite. A fragment of muscovite quartz rock (gneiss?) is present. Reddish brown opaques are fairly abundant. | The rock is a mixture of sericite, chlortte, quartz and calcite. Sericite is the most abundan mineral and forms fine aggregates. Chlortte comprises replacement of cubental malic minerals. | Aggregates of chlorite, calcite, muscovite, and opage minerals are set in a cryptocrystalline matrix of sericite, quartz, and chlorite. Original textures and fabrics are almost completely altered. | Pseudomorphs after plagicolase consisting of calcife, quartz, and chlorite retain an original intergramlar fabric. Mafic minerals are altered to an aggregate of calcife, chlorite, and opaque minerals. Matrix is composed of sericite, quartz, calcife, and feldspar, with small quantities of sphene. | The rock consists of partly altered plagioclase laths and completely altered intergranular mafic minerals, composed of calcife, chlorite, and opaque minerals. Plagioclase is albitized. Considerable amounts of sphene are present. | The rock consists of oligoclase laths showing subtrachytic fabrics and oraques with minor sphene. Veins and clots of calcite, feldspar, and chlorite are present. |

| Remarks | See microphoto. No.5 | | See microphoto. No.6 | |
| Microscopic Observations | Subangular to subrounded fragments of andesite, rhyolite, shale, and chert and quartz and feldspar grains are set in a fine-grained matrix of quartz and sericite. Calcite and sericite are partly abundant. | Subrounded and rounded grains of quartz, plagioclase, K-feldspar, opaque minerals, epidote and rock fragments occur in a fine grained matrix. They measure 1.0 to 0.1 millimeters across and average about 0.3 millimeters. The rock fragments are mainly of andesite, quartz porphyry and low grade shist. | A trachyte fragment contains large tabular phenocrysts of potasstum-feldspar in an orthophyric groundmass consisting of small stout crystals of alkli-feldspars, opaques, and epidote. The matrix consists of quartz grains, calcite pseudomorphs after pyroxene?, andesite chips, epidote, and opaque minerals. | |

|----------|------------|--------------|---------------------|---|--------|
| DH-No. 1 | 80.00m | Basal Series | Graywacke sandstone | Pyrite is the only essential opaque mineral and is disseminated in the specimen. It measures mostly 1.0 to 0.1 millimeters in size. Graphite and rutile are also present but in small amounts. Goethite occurs as a late supergene mineral. | |
