z		5					

Sample No. : S0102

Locality : JMS-1 14.0m Sector : Songwe Rock name : White Colored Carbonatite

Observation Note:

The spacimen is white colored carbonatite weakly

disseminated with pyrite.

Pyrite occurs as an euhedral grain less than 0.2 mm in diameter. Pyrrhotite occurs as small amoeboid-shape inclusions in some pyrite.

Rutile show mosaic intergrowth in botryoidal mass,

which might be the pseudomorph after ilmenite.

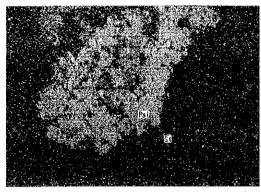

(2)

Sample No.: S0204 Sector : Songwe Locality : JMS-2 Rock name : Reddish oxidized rock Observation Note:

Observation Note:

Opaque minerals are rare, and are scattered widely.

Psilomelane like mineral shows creamy to greyish white color with strong anisotropy. The minerals form botryoidal aggregate of minute acicular crystals. The qualitative analysis by EPMA shows the existence of Ba, Ca, Zn, Fe and K Goethite coexists with psilomelane like minerals in the botryoidal aggregate. The other occurrence of goethite shows concentric zonal texture that suggests the decomposition from pyrrhotite or pyrite.

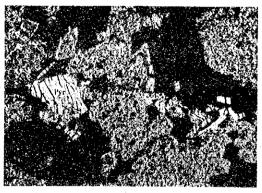

0.2mm

(3)

Sample No.: S0207 Locality : JMS-2 Sector : Songwe 40.8M Rock name : Massive oxidized Fe-Mn ore. Observation Note:

The EPMA analysis and microscopic observation suggest that there are two kinds of minerals of Mn-O system. Both minerals occur as coarse ( less than 0.1 mm in diameter ) euhedral tabular or prismatic crystals. One shows creamy greyish color with strong anisotropy. Twinning and cleavage greyish color with strong anisotropy. Twinning and cleavage vertical against to twinning plane are observed. The other shows more yellowish color with distinct anisotropy. The former might be pyrolusite and the latter ramsdellite. These minerals are often enclosed in the aggregate of the fine grains of goethite and psilomelane like minerals. Psilomelane like mineral shows color of bluish grey to greyish white with etrong anisotropy. white with strong anisotropy.

Hematite also occurs as mosaic intergrowth with Mnminerals and goethite. Magnetite occasionally occurs as euhedral grains, and is decomposed into hematite with lattice-shaped replacement texture.

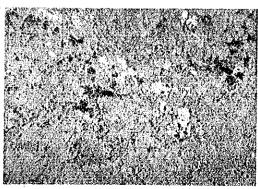

**(4)** 

Sector : Songwe Locality: JMS-3 52.5m Rock name : Carbonatite Observation Note :

The spacimen is composed essentially of white carbonatite with mosaic texture.

Pyrite occurs as euhedral grain less than 0.2mm in diameter and is not so common. goethite is also small in amount and shows close intergrowth with carbonate.

Pyrochlore occurs as an euhedral to subhedral grain less than 0.2mm in diameter and is scattered widely in carbonate mass.

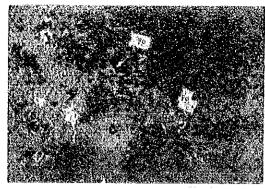

0.5mm

(5)

Sample No.: S0403
Contar: Songue Locality: JMS-4 29.0m

Sample No.: \$0403
Sector: Songue Locality; JMS-4 29.0m
Rock name: Carbonatite
Observation Note:
The spacimen is dark brown carbonatite with abundant goethite. Opaque minerals are rare and are scattered widely.
Goethite occurs as anhedral grains and is usually found associated with calcite, suggesting that these minerals are derived from ankerite. A small amount of cubic grains like pyrite is also observed, but is completely replaced by Fe-oxide.

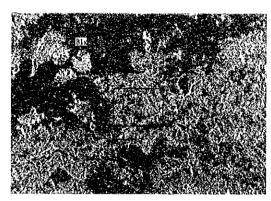

\_\_\_\_

**(6)** 

Sample No.: S0605 Locality: JMS-6 14.6m Sector: Songwe Locality Rock name: Oxidized Fe-Mn ore.

Rock name: Oxidized Fe-Mn ore.
Observation Note:
Bixbyite or jacobsite like minerals occur as euhedral crystals or granular aggregate. The mineral shows brownish gray color and isotropy. The qualitative analysis shows Fe-Mn-oxide. Partly the mineral is decomposed to intergrowth of hematites and braunite like minerals. Braunite like mineral forms finely granular masses. The enclosed photograph of X-

forms finely granular masses. The enclosed photograph of X-In some parts, goethite are also associated with hematite and Mn-minerals. They occur as fine irregular crys-

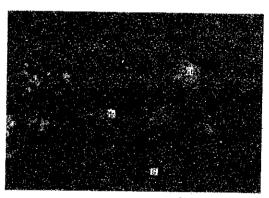

<u>}----</u>

7

Sample No. : JMS6 Sector : Songwe Locality : JMS-6 40 Rock name : Pinkish oxidized igneous rock Locality : JMS-6 46.2m

Rock name: Pinkish oxidized igneous rock
Observation Note:
Opaque minerals are rare, and primary mineral is only
pyrite which occurs as euhedral grain of about 0.02 mm in
diameter. Many pyrite grains have changed to geothite which
form cubic pseudomorph. Some goethite might be decomposed from
pyrrhotite. Only one grain of relic pyrrhotite is observed in
the geothite. Rutiles are scattered in the spacimen, and the
fine crystals form irregular-shaped aggregate. Small anhedral
Mn-oxide minerals occur in the boundary between rock-forming
minerals.

0.155

(8)

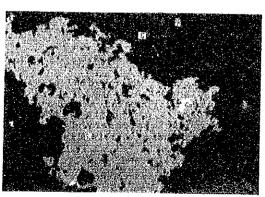

Sample No. : S0801 Sector : Songwe I Rock Name : Carbonatite Locality: JMS-8 2.3m Observation Note: Opaque min

mineral is very rare. and shows simple

assemblage.

Magnetite occur as euhedral to subhedral primary rockforming minerals. The grain size is less than 0.1 mm in diameter. Hematite occurs in the margin of magnetite, and looks like decomposed crystal from magnetite, in spite of the lack of lattice-shaped replacement texture.

Sphalerite occurs as irregular form and shows rather distinct internal reflection. Some sphalerite grains include small grains of galena (3 micron in diameter) and pyrite (5 micron). Pyrite also occurs as coarse euhedral crystal less than 0.5 mm in diameter. Those pyrites contain small inclusions of pyrrhotite. inclusions of pyrrhotite.

0.1mm

(9)

Sample No. : \$1003

Sector : Songwe Locality: JMS-10 13.9m

Rock name : Carbonate silicate rock

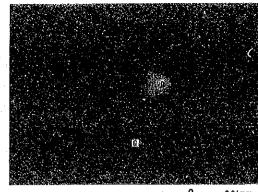

Observation Note:

Opaque minerals are rare, and are disseminated widely

in the spacimen.

Rutile shows subhedral to anhedral shape, and the grain size is less than 0.1 mm in diameter. Pseudobrookite occurs in the rutile with sandwitch texture, and also occurs as single irregular grain. There are a few very small grains showing bright yellowish color without anisotropy. EPMA analysis shows Ca, Al, Fe and Mn oxide but mineral name could not be determined.

Pyrite occurs as enrounded form, and the margin is decomposed into goethite. Occasionally galena occurs as small (less than 0.03 mm) anhedral grains.

0.04mm

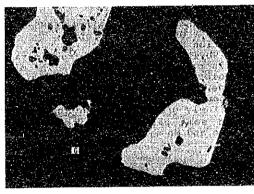

(10)

Sample No.: S1006 Sector : Sonawe Locality : JMS-10 25.0m Rock name : Pinkish carbonatite

Observation Note:

Coarse grains of pyrite are disseminated in the spacimen. Pyrite occurs as euhedral to subhedral grains less than 0.2 mm in diameter, with abundant inclusions of gangue minerals. Galena is rarely observed in the grain boundary of pyrite and in gangue minerals. The grain size is apploximately 0.1mm in diameter. Pyrrhotite also occurs as amoeboidshaped inclusions in pyrite. Marcasite like mineral is rarely observed. The grain size is so small to identify in detail.

Fe bearing rutile occurs as aggregate with mozaic texture. It is common to be associated with monazite like minerals.

0.2csm

Sample No.: S1009 Locality: JMS-10 33.8m Sector : Songwe Rock name : Brownish layered carbonatite Observation Note:

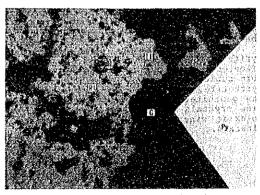

The spacimen shows slightly layered texture, and a

layer is enriched in opaque minerals.

Pyrite occurs as large euhedral grains less than 1.0 mm in diameter, and includes many inclusions of pyrrhotite,

sphalerite, galena and other gangue minerals.

More predominant opaque minerals are aggregate of rutile and ilmenite with mosaic texture, Rutile contains niobium and vanadium (qualitative results from EPMA), hence it might be better to call Nb-rutile. Ilmenite contains neither Nb nor V, but only contains small amount of Ca and Mn. Small amount of magnetite can be observed as relic crystals that is decomposed into hematite in the

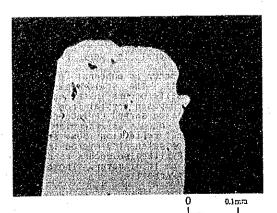

0.10.53 -

Sample No. : S1015 Sector : Songwe Locality: JMS-10 49.8m Rock name : Carbonatite Observation Note:

Small amount of pyrite are scattered widely in the

spacimen.

Pyrite occurs as euhedral or subhedral grain of about 0.3 mm in diameter and small grain of 0.01mm in diameter. The large grain contains small amoeboid-shaped pyrrhotite. The grain size of pyrrhotite is from 0.01mm to 0.05mm. Small pyrite is sometimes observed in the monazite like gangue minerals. The shape is irregular. The other mineral can not be observed.

(13)

Sample No. : S1105

Sector : Songwe Locality : JMS-11 16.4m Rock name : Brownish oxidized carbonatite

Observation Note:

Opaque minerals occur commonly as botryoidal masses

composed mainly of Mn-oxide minerals.

Psilomelane like minerals show bluish grey to greyish white color with strong anisotropy. The forms are aggregates of minute acicular crystals with goethite. According to EPMA analysis, the psilomelene like minerals contains some amount of Ba (result from EPMA). Other Mn-minerals might also be contained in the botryoidal masses. Some geothite shows concentric zonal replacement texture, which might be pseudomorph from pyrite or pyrrhotite.

Magnetite occasionally occurs as euhedral grains, but

almost whole area is decomposed to hematite with lattice-

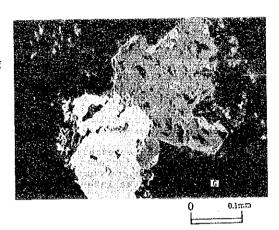

shaped texture.

(14) Sample No. : T0106 Sector: Tundulu Locality: JMT-1 22.6m Rock name: Carbonate silicate rock Observation Note:

Magnetite occurs as euhedral to subhedral grains of about 0.2 mm in diameter. Ilmenite occurs in magnetite grain showing sandwitch or lamellae texture. Hematite occurs as irregular shape in the margin of magnetite grain. Also hematite occurs along the ilmenite lamella in magnetite.

Tabular-shaped rutile occurs associating with magnetite.
Pyrite occurs as euhedral to subhedral grain including small spots of pyrrhotite. Sometimes pyrite is decomposed to geothite which shows concentric zonal texture. Marcasite is associated with pyrite as lath-shaped intergrowth, which

might be decomposed from pyrrhotite.

(15) Sample No. : T0108 26.8m Sector : Tundulu Locality : JMT-1 Rock name : Heterogeneous carbonatite Observation Note:

The specimen is composed of melanocratic, brownish and

leucocratic parts.

Manetite occurs as euhedral grains of 0.3-0.5 mm size in the melanocratic part. The margin is decomposed into hematite. Lattice-shaped replacement texture is not common. Pyrite occurs as euhedral to subhedral grains less than 0.5 mm in diameter, and is associated with lath-shaped marcasite. Rutile occurs as tabular-shaped euhedral grain.
Pyrrhotite is included as spotted or amoeboid-shaped

crystals in pyrite grain. Sphalerite also coexists with

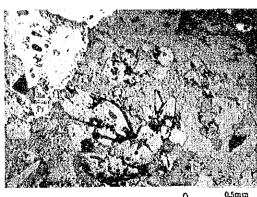

Sample No.: T0113 Sector : Tundulu Locality: JMT-1 42.7m Rock name : Carbonatite

Observation Note:
The spacimen is white colored carbonatite, associated with

biotite and aegirine.

Pyrite is found as anhedral to subhedral grain less than 0.3mm in across and sometimes alter to hematite in the margin of it.

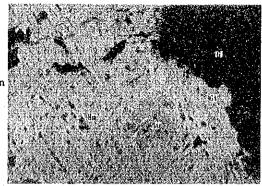

A small amount of goethite is also observed.

Sample No.: T0209 Sector : Tundulu Locality : JMT-2 44.4m Rock name : Carbonatite with botryoidal masses Observation Note:

Opaque minerals occur commonly as botryoidal masses composed mainly of iron oxide minerals.

Magnetite occurs as euhedral to subhedral grains of 0.1 to 0.5 mm in diameter, and is oxidized to hematite with lattice-shaped replacement texture. Occasionally outer margin of these iron oxide is enclosed by goethite. Goethite is also decomposed from pyrite or pyrrhotite, and shows concentric zoning. Rutile forms aggregate of tabular crystals, and also shows myrmekitic intergrowth with gangue minerals.

0.1mm

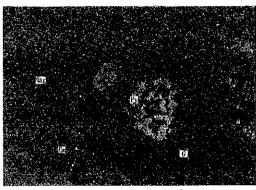

Sample No.: T0210 Sector: Tundulu Locality: JMT-2 45.5m Rock name: Oxidized carbonatite with botryoidal masses. Observation Note:

Primary assemblage of opaque minerals might be

magnetite, rutile and pyrite.

Magnetite is euhedral to subhedral. The grain size is less than 1.0 mm, and the magnetite is decomposed into hematite in the margin with lattice-shaped texture. Rutile occurs as an euhedral grain. The aggregate of rutile, pseudobrookite and hematite might be pseudomorph from ilmenite.

Pyrite occurs as euhedral to subhedral grains of about 0.3 mm size, and often includes small grains of hematite and goethite. Some pyrite are coated by geothite. Marcasite is occasionally observed as lath-shaped texture.

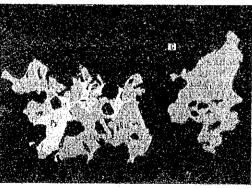

\_\_\_\_

Sample No.: T0602 Sector : Tundulu Locality : JMT-6 6.50 Rock name : Fresh carbonatite with banding structure Observation Note:

The spacimen shows banding structure, and opaque mine-

rals are scattered in the one layer.

Magnetite occurs as euhedral to subhedral grains of about 0.3 mm in diameter. Some magnetites contain the exsolution lamellae (1 micron wide) of spinel like gangue minerals and ilmenite. Ilmenite also occurs as myrmekitic intergrowth with gangue minerals. Hematite occurs in the margin of magnetite and along the ilmenite lamellae. Rutile is also observed, and coexists with pyrite. Pyrite and pyrrhotite coexist together, and the latter is partly decomposed into marcasite.

0.1mm \_

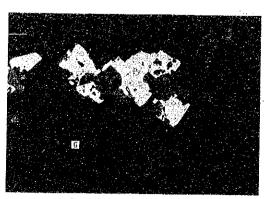

(20)

Sample No. : JMT6 Locality : JMT-6 18.6m Sector : Tundulu

Rock name: Carbonatite with veinlet of opaque minerals
Observation Note:

The opaque mineral assemblage is very simple in
spacimen. Pyrite occurs as euhedral to subhedral grains. simple in large grains contain small spots of pyrrhotite. Marcasite occurs as lath-shaped grains, decomposed from pyrrhotite, and is associated with pyrite.

In the country rock opaque mineral is not observed.

Sample No. : T0608

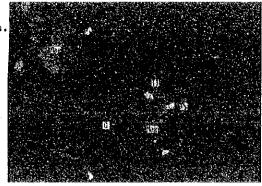

Sector: Tundulu Locality: JMT-6 46.6m Rock name: White carbonatite with a layer of opaque minerals. Observation Note:

Opaque minerals occur in a layer and its assamblage is

rather simple.

Magnetite occurs as euhedral to subhedral grains less than 0.1 mm in diameter, and has remained unchanged to hematite. Ilmenite occurs mainly as tabular-shaped euhedral grains. Also ilmenite occurs as exsolution lamellae in magnetite, and as myrmekitic intergrowth with other ganque minerals.

Pyrite occurs as euhadral to suhedral grain, coexisting with magnetite and ilmenite. Partly pyrite is associated with marcasite.

(22)

Sample No. : T0707

Sector : Tundulu Locality : JMT-7 21.0m

Rock name : Magnetite-carbonatite
Observation Note :

Opaque minerals are a small amount of magnetite, hematite, goethite, Fe-Mn oxide and rutile, with accessory pyrite.

The primary minerals may be magnetite and ilmenite, which are decomposed strongly to oxidized phases.

Magnetite occurs as an euhedral grain less than 0.1mm in diameter and is decomposed to hematite with lattice-shaped replacement texture.

Hematite occurs as anhedral grains concentric zonal texture with goethite,

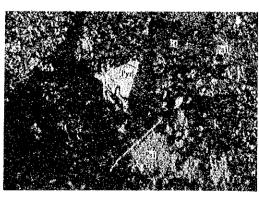

Sample No. : T1004

Locality: JMT-10 27.7m

Sector: Tundulu Locality: JN Rock name: Massive oxidized Mn ore

Observation Note:

There are two kinds of minerals of Mn-O systems. Both minerals occur as euhedral tabular or prismatic crystals. One shows creamy greyish color with strong anisotropy. Twinning is observed, and the cleavage is vertical against to twinning plane. The other shows more yellowish color with anisotropy. The former might be pyrolusite and the latter ramsdellite. These minerals are often enclosed in the aggregate of the small grains of goethite and psilomelane like mineral. The psilomelane like mineral forms finely crystalline aggregates, and often shows the myrmekitic like intergrowth with goethite (result from EPMA).

Sample No.: T1204

Locality: JMT-12 13.9m Sector : Tundulu

Rock name : Layered carbonatite

Observation Note:

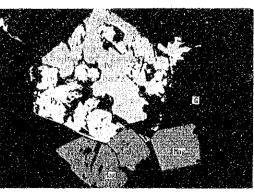

The spacimen shows layered structure composed of leucocratic and melanocratic parts. Opaque minerals sactter

mainly in the melanocratic part.

Magnetite occurs as ewhedral to subhedral grains of about 0.1 mm in diameter. Ilmenite occurs also as tabular euhedral grains, and occasionally shows eutectic intergrowth with gangue minerals. The exsolution lamella of ilmenite is rarely observed in magnetite. Rutile occurs as euhedral

grains of 0.05 mm size, but is not common.

Pyrrhotite occurs as euhedral grains less than 0.1 mm in diameter, and is associated with pyrite. Pyrrhotite is partly decomposed to marcasite, and also partly decomposed to unknown minerals. This mineral is situated between fresh pyrrhotite and marcasite, the sulfur content is same with that of pyrrhotite, but the iron content is similar to that of pyrite. The qualitative data shows the existence of oxygen. Hence this is thought to be metastable oxidized pyrrhotite.

(25)

Sample No.: T1216 Sector : Tundulu Locality : JMT-12 47.9m Rock name : Carbonatite Observation Note:

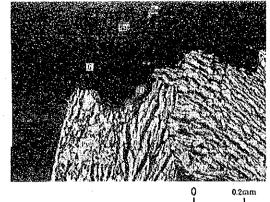

Small amount of opaque minerals are scattered widely in

the melanocratic part of spacimen.

Magnetite is euhedral of about 0.1 mm size. Hematite coexists closely with magnetite. In spite of the lack of coexists closely with magnetite. In spite of the lack of lattice-shaped replacement texture, hematite looks oxidation product from magnetite. Occasionally rutile occurs as euhedral grains of about 0.05 mm in diameter.

Pyrite occurs as subhedral grains of 0.2 mm, and anhedral grains if it is associated with marcasite. Marcasite shows lath-shaped texture. Pyrrhotite occurs as a machoid-shaped inclusions in purite.

amoeboid-shaped inclusions in pyrite.

Sample No. : T1610 Sector : Tundulu Locality : JMT-16 45.2m

Rock name: Carbonatite
Observation Note:
The spacimen includes a small amount of pyrochlore, rutile

The spacemen includes a small amount of pyrochiote, futile and goethite, with accessory pyrite.

Pyrochlore is found as an euhedral grain less than 0.2mm in across and is scattered in carbonate mass.

Goethite shows network texture and forms a cubic pseudomorph

after pyrite. Rutile occurs as an euhedral grain less than 0.1mm in across and is scattered widely.

Sample No.: T1611
Sector: Tundulu Locality: JMT-16 50.0m
Rock name: Sulfide bearing carbonatite
Observation Note:

Rock name: Sulfide Dearing Carbonatite

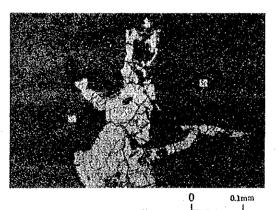

Observation Note:

The spacimen includes a small sulfide mass.

It is composed mainly of sphalerite and pyrite, with subordinate amounts of goethite, chalcopyrite and covellite. Sphalerite shows coarse-grained, euhedral crystals and includes many tiny blebs of chalcopyrite.

Dearite occurs enhedral to subhedral grains, sometimes veinlets

Pyrite occurs euhedral to subhedral grains, sometimes veinlets in the cracks. A small amount of covellite is found in the margin of spharelite.

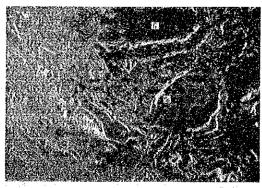

(28)

Sample No.: T2201 Sector : Tundulu Locality : JMT-22 11.3m Rock name : Fe-Mn ore Observation Note : Opaque minerals

Opaque minerals are only Fe-Mn oxide occurs as fine-grained, subhedral to anhedral grains and is scattered widely.

It shows sometimes a kind of concentric zonal texture.

0.1mm

Sample No.: T2211 Sector : Tundulu Rock name : Fe ore

Locality: JMT-22 46.9m

Observation Note:
The spacimen includes many kinds of iron minerals and rutile as opaque minerals.

Iron minerals are pyrite, goethite, magnetite, marcasite and pyrrhotite.

Pyrite occurs as euhedral to subhedral less than 2.0mm in across and is partly decomposed to goethite with graphic repalcement texture.

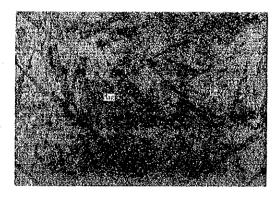

Magnetite, less than 0.05mm in across, and rutile, less than 1.0mm in across, are scattered widely in gangue minerals and small in amount.

(30)

Sample No. : Nata 1 Sector : Tundulu Locality : Surface Rock name : Fe ore

Rock name: Fe ore
Observation Note:
The spacimen is a massive hematite-magnetite ore.
It consists essentially of hematite and magnetite, with accessory ilmenite and goethite.
Magnetite is decomposed strongly to hematite with lattice-shaped replacement texture.
Hematite replaces magnetite and forms exsolution intergrowths with ilmenite and/or goethite. with ilmenite and/or goethite.

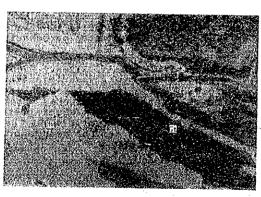

0.04mm

(31)

Sample No.: Nata 2
Locality: Surface

Observation Note : The spacimen is very similar to sample no. Nata 1, but consists mainly of hematite and goethite, with a subordinate amount of Fe-Mn oxide. amount of re-Mn oxide. Hematite and goethite make an aggregate with cell-shaped network and concentric zonal structure. Hematite consists of the margin of the cell-wall and goethite is observed in some of the inside of cell. The other inside of cell are vacant, suggesting that goethite has been discolved. has been dissolved.

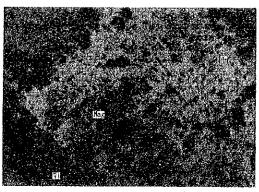

(32)

Sample No.: 7YR2 Sector : Songwe Locality : Surface Rock name : Fe ore Observation Note:

The spacimen is compact magnetite ore. Magnetite occurs as euhedral or subhedral grains, and is decomposed strongly to lattice-shaped hematite. The pseudomorph from tabular-The pseudomorph from tabularshaped ilmenite occurs in the magnetite or its bouundary.
The pseudomorph consist of the mosaic or irregular intergrowth of rutile, hematite and pseudobrookite. The color of
hematite is slightly darker than that in magnetite, then it
is possible to be ilmeno-hematite or hemo-ilmenite.

Geothite is also observed in the grain boundary of
magnetite with concentric zonal pseudomorph, which is decomposed from parite or parrhotite.

posed from pyrite or pyrrhotite.

0.04mm

(33)

Sample No.: 7YR14

Sector : Songwe Locality : Surface

Rock name : Strongly oxidized Fe-Ti vein in carbonatite

Observation Note:

Fe-Ti oxide vein of 5 mm in wide and narrow veinlet of 0.1 mm are observed in the spacimen. The vein is compoused of massive part and cell-shaped networks. The principal minerals may be magnetite and ilmenite which decomposed strongly to oxidized phases.

Magnetite occurs as euhedral grain in the massive part,

and is decomposed to hematite with lattice-shaped replacement texture. Magnetite remains as a relic mineral. The tabular-shaped pseudomorph from ilmenite is observed in the massive part, and is aggregate of hematite, pseudobrookite and rutile. The primary ilmenite is not observed even as a relic mineral.

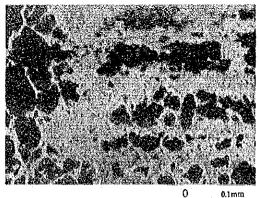

The cell-shaped network part consists of rutile and hematite and goethite. Rutile occupies mainly the central zone of the cell-wall like network. Hematite consists of the margin of the cell-wall. Goethite is observed in some of the inside of cell. The other inside of cell are vacant, that suggest the dissolution of goethite.

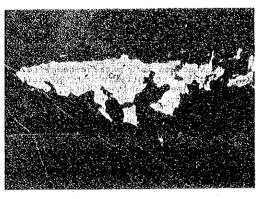

Sample No.: 7Y030 Sector : Songwe Locality : Surface Rock name : K-feldspar rock Observation Note:

Opaque mineral is rare in the carbonate mineral, and

Opaque mineral is rare in the carbonate mineral, and fills only the cracks of carbonate mineral.

Cryptomelane like mineral is cementing the clacks of carbonates. The mineral shows white to bluish greyish color, and distinct anisotropy. The mineral forms aggregate of minute acicular crystals, and contains K, Ca, Ba, Fe, and Zn other than Mn. Pyrolusite like mineral occurs also in the crack. The optical properties are similar to those of cryptomelene like mineral, but the mineral forms narrow veinlet (2 - 5 micron in wide), or aggregate of small mosaic crystals, and contains less K and Ba.

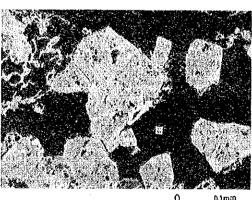

0.1553

Sample No.: 7Y167 Sector : Tundulu Locality : Surface Rock name : Iron concentrated carbonatite

Observation Note: This specimen is predominant in magnetite, pyrite (?) and their oxidized phases. Primary magnetite occurs as euhedral grains of 0.1 to 0.2 mm in diameter. Hematite occurs in the margin of magnetite grains with lattice-shaped texture. Only one relic grain of pyrite is observed in the geothite, and many pseudomorphs composed of goethite show concentric zonal texture. The pseudomorph shows the latter crystallization than magnetite, and the pseudomorph can be thought to be drived from pyrite.

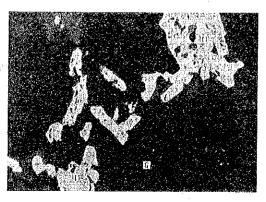

Sample No.: 7Y174

Sector : Tundulu Locality : Surface Rock name : Fresh equigranular Carbonatite Observation Note:

Predominant opaque minerals is only ilmenite which

occurs as tabular euhedral grains of about 0.05 x 0.2 mm

Rutile and pyrite are rare minerals. Very fine grains (about 10 micron in diameter) of rutile occur in the ilmenite and other gangue minerals. Pyrite also occurs as very fine euhedral grains (about 5 micron size) in gangue minerals.

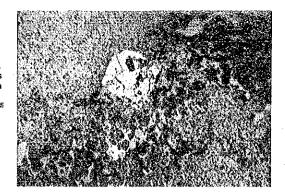

(37)

Sample No.: 7Y179 Sector : Tundulu Locality : Surface Rock name : Carbonatite

Observation Note:
The spacimen is goethite-rich carbonatite with lamination. Opaque minerals, except goethite, are rare. Goethite occurs as subhedral to anhedral grains and forms an aggregate with

A small amount of pyrochlore is found as anhedral grain less than 0.3mm in diameter, closely associated with synchisite, rare metal-rich mineral and spatite.

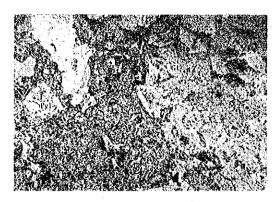

0.5mm

(38)

Sample No.: 7Y181 Sector : Tundulu Locality : Surface Rock name : Carbonatite Observation Note:

The spacimen is very similar to sample no.7Y179 in their mineral assemblages.

Goethite is predominant and forms usually an agregate like a pseudomorph after ankerite with calcite. Pyrochlore is found as an euhedral grain less than 0.3mm in diameter and coexists commonly with synchisite and Ti-minerals in the apatite-quartz-rich mass.

0.5mm

(39)

Sample No.: 7Y211 Sector : Tundulu Locality : Surface Rock name : Brownish oxidized carbonatite Observation Note:

The spacimen strongly oxidized and opaque minerals are primary Fe-Mn minerals and secondary ones.

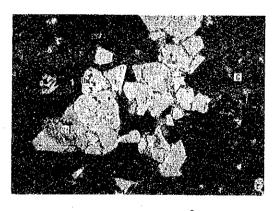

Magnetite occurs as ewhedral to subhedral grains less than 0.3 mm in diameter, and is strongly decomposed to lattice-shaped hematite in the margin. Ilmenite is completely decomposed to rutile, pseudobrookite and hematite.

Two kinds of Mn-O minerals occur as tabular or prismatic crystals. One shows creamy greyish color with strong anisotropy. Twinning and well-developed cleavage are observed. The other shows more yellowish with distinct anisotropy. These might be pyrolusite and ramsdellite. These minerals are decomposed to the aggregate of small psilomelene like minerals (according to the data from EPMA, small amount of Ba, Al, Fe, and Si are ditected).

Psilomelane like minerals shows color of bluish grey to around the strong product of the strong product

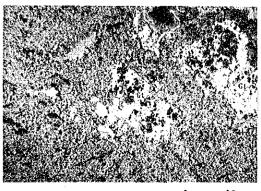

greyish white, and strong anisotropy. The mineral often shows the myrmekitic like intergrowth within the gangue

minerals.

Sample No. : 7Y226 Sector : Kangankunde Rock name : Carbonatite
Observation Note:

Rock name: Carbonatite
Observation Note:
The spacimen is greenish, monazite-rich carbonatite.
Monazite is mostly fine tabular mineral, occuring as an aggregate in the carbonate-quartz mass.
Opaque minerals ar only goethite. Goethite is found as subhedral to anhedral grains, closely associated with carbonate and apatite.
