ANNEX-I WATER BALANCE

I.1 INTRODUCTION

This ANNEX presents the results of the water balance study, which was made based on the results of hydrological study in ANNEX-B, and study on irrigation water demand in ANNEX-F and on hydropower in ANNEX-G, to formulate an overall agricultural development plan in the NWDZ and NCRB areas.

The aims of the water balance study are to determine irrigation areas, required capacities of conveyance system and reservoirs within an allowable water deficit. As studied in ANNEX-H, there are several alternative plans for transbasin conveyance system from the Mahaweli Ganga to the NCRB area, including possibility to increase the diversion water at Polgolla to the Sudu Ganga. All these alternative plans were simulated by using the water balance simulation model, and all the results were incorporated into formulation of an overall development plan in the study area.

1.2 CONDITION OF WATER BALANCE

1.2.1 Division of Basins

The Mahaweli river basin and other river basins in the study area were divided into 72 sub-basins, considering the existing and potential dams and intake sites, as well as existing and potential irrigation areas. The basin model for the water balance is schematically presented on Figs. I.2-4 to I.2-7 depending on the conveyance system to be selected. Though there are numerous tanks in the study area, only major existing tanks with an active capacity of more than 5 MCM and the proposed tanks are considered in this division of basins.

Catchment area and average monthly runoffs of the respective sub-basins are presented in Tables I.2.1 and I.2.2. The details are discussed in ANNEX-B.

I.2.2 Transbasin Conveyance Systems

There are several transbasin diversion plans from the Mahaweli Ganga to the NWDZ and NCRB areas studied by UNDP/FAO, subsequently in the ISS and in the TDS. The details are discussed in ANNEX-H.

The following these alternatives to convey irrigation water to the NCRB area were selected:

Case A: New Alternative Plan (See Fig. I.2-1) Minipe - New LB canal - Minneriya tank (Pumping station) - NCP canal

Case B : Elecrowatt (TDS) Solution Modified (See Fig. I.2-2) Minipe - Hettipola Oya (Pumping Station) - Kalu Ganga dam - Elahera - NCP canal (NEDECO route)

Case C: UNDP/FAO (ISS) Solution revised by NEDECO (See Fig. I.2-3) Minipe LB canal - Angamedilla (Pumping Station) - NCP canal

The schematic system diagrams mentioned above are shown on Figs. I.2-4 to 1.2-6.

As discussed in ANNEX-H, Bowatenna - Kalawewa - Mahakatunoruwa - Galgamuwa tanks route was adopted as the NWDZ conveyance system. The schematic flow diagram is shown on Fig. I.2-7.

I.2.3 Natural River Flow

The most important factor for the water balance study is to correct the reliable flow data, which will affect the quality of the study. Flow data for the Mahaweli Ganga and Amban Ganga were scrutinized in the HCP and prepared the data-base system on the weekly basis at each of the major structures and ganging stations.

In the MWRMP, the weekly flow data were recompiled into monthly basis for 31 years (1949-81), considering the existence of series of large storage reservoirs. The monthly natural river flow data complied in the MWRMP for the period of 1949-81 were adopted in the present study. Moreover, additional flow data for the period of 1981-86 could be utilized for the study. However, series of multipurpose dams on the Mahaweli Ganga and Amban Ganga, as well as the irrigation development projects have been performed since the late 1970s. In order to keep the continuity of the data base, all the measured river flows were converted to the natural river flow for the local catchment area.

As discussed in ANNEX-B, local inflows to the respective irrigation tanks were calculated by using available measured flows, or in case of missing data, by sorting rainfall-runoff correlation method to estimate the runoff coefficient in the catchment area.

The average natural river flow (1949-86) at the major control points such as reservoirs, tanks and diversion point are summarized in Tables I.2.1 and I.2.2. The monthly inflow data at the existing and proposed dam sites and major structures are given in ANNEX-B.

1.2.4 Irrigation Water Demand

The irrigation water demand for respective existing, on-going and committed projects under the AMDP as well as potential irrigable areas was calculated on monthly basis for 37 years from October 1949 to September 1986, using Penman formula. The present overall irrigation efficiency was evaluated to be 50% for Systems E and C, and 56% for other systems. The irrigation demand at the matured stage in the year 2020 was calculated by adopting an improved overall irrigation efficiency of 60%, since the GOSL puts enforce the rehabilitation of existing projects to improve farming practices and to save water through proper water management.

The average monthly irrigation demand for respective projects and schemes is presented in Tables I.2.3 and I.2.4, and the details are described in ANNEX-F.

I.2.5 Return Flow

Return flow from irrigation schemes located in the upper stream is considered as usable water resources for the downstream areas. Ratio of return flow to diversion irrigation water is generally considered in a rage of 0.20-0.30. In this study, there is no actual measurement and assessment of the return flow, it is assumed to be 0.25 of the diversion water requirement. Reusable return flows are schematically shown on Fig. I.2-8.

I.2.6 River Maintenance Flow

As discussed in ANNEX-B, the river maintenance flow is the indicator of the allowable limit of water withdrawal from the river, to be considered in allocating and developing water resources. Increased water withdrawal should not be allowed, if it is expected to impair the river maintenance flow frequently.

As seen in Table I.2.5, the minimum river flow at Manampitiya has been substantially decreased with the progress of land and water resources development since 1976. The requirement for the river maintenance flow should be determined for each river, based on the conditions particular to the river. The river maintenance flow at Manampitiya was decreased for last 12 years, however it seems that there was no serious problem. The results of the flow duration analysis show that the average river flows during the low flow period (flow kept more than 275 days of the year) and the extremely low flow period (355 days) were estimated at 31 m³/sec and 14 m³/sec for the period of 1976-87, respectively.

Usually the river maintenance flow ranges between the above two figures. Therefore, since there is no such available data and studies, the maintenance flow at the estuary was preliminarily assumed to be 15 m^3 /sec for the water balance study, referring to the results of the flow duration analysis at Manampitiya, and irrigation demand for the existing Allai scheme of 7,000 ha of which the intake is located at Manampitiya downstream.

I.2.7 Reservoir and Tank Parameters

In the Mahaweli river basin, there are six (6) existing multipurpose dams, i.e. Kotmale, Polgolla, Victoria, Randenigalla, Bowatenna, Maduru Oya. The Rantembe dam is under construction and will be completed in 1990. Moreover, the GOSL has decided to implement the Moragahakanda dam. These eight multipurpose dams are considered as the existing dams in this master plan.

There are nine (9) candidate dam and hydropower schemes and 15 candidate irrigation tanks. Tables I.2.6 to I.2.8 present the principal features of existing and candidate dams and tanks. Tables I.2.9 and I.2.10 show parameters adopted in the water balance simulation.

I.3 SIMULATION MODEL

I.3.1 Simulation Model

A simulation model was developed to represent a water resource system by adopting modes, with or without storage, which are connected by channels having flow limits, based on the schematic flow diagramme shown on Figs. 1.2-4 to I.2-7.

Since there are numerous irrigation tanks in the existing and potential irrigation areas, in the model a certain simplification for irrigation system was introduced in representing irrigation systems. Reservoirs or tanks with an active storage of more than 5 MCM were basically incorporated into the model.

In representation of the reservoir system, active reservoir storage was divided into 9 zones for the reservoir operation as illustrated on Fig. I.3-1. Each storage zone has a purpose in storing and releasing water according to system water demand such as flood control, flow conservation and augmentation, etc. Each zone has a upper and lower boundary, and is specified within a space between the high water level (HWL) and the low water level (LWL) of a reservoir.

The upper zone (zone-1) is used for the flood surcharge storage space, the lowest zone (zone-8) for dead water storage, and the zone-7 only for a firm energy generation. The upper and lower rule curves were fixed on the basis of a try and error method, referring to the study results of the MWRMP for the existing dams, to maximize power generation as well as to minimize water deficit in irrigation areas and spillout from respective reservoirs and tanks.

With regard to multipurpose dams, the following operation rule is given:

- In case that reservoir water level at a certain time is higher than the lower rule curve (above the 6th zone), water is released to meet downstream irrigation water demand or to maintain a firm power generation, which is greater.
 - In case that reservoir water level is lower than the lowest rule curve (within the 7th zone), water is released to maintain only a firm power generation.
 - As a first trial, water balance from the upper to lower reservoirs is carried out to maintain a firm generation at each hydropower station. In case of irrigation water demand being higher than demand for a firm generation, water release is first made from a reservoir or tank with the highest zone among all multipurpose dams and irrigation tanks, and if not to meet the irrigation demand, a downstream reservoir with the 2nd highest zone releases water to meet irrigation demand.

Conceptional flow chart of the simulation model are illustrated on Fig. I.3-2.

1.3.2 Reservoir and Tank Operation

(1) Operation Rule for Main System Reservoirs

For the water balance study, the operation methods of the existing and proposed dams were set at the variable draft operation considering the characteristics of the multipurpose dams, except the proposed Talawakele, Watawela, Uma Oya Scheme-500 hydropower stations which are the river run-off type. Even though existing dam series in the Mahaweli river basin including several steps of transbasin diversion are so complicatedly connected, all the multipurpose reservoirs were set at the variable draft operation to release water to downstream, according to the downstream water demand keeping the present water rights for water users.

The Polgolla diversion policy is the most important key factor for the formulation of a future development policy and plan. Comprehensive economic and social benefit as a whole should be taken in consideration. At Polgolla, water demand for the Amban Ganga will be released through the power channel with maximum discharge of 148 MCM per month.

The principal concept of the rule curve for the main system reservoirs would be to maximize the overall hydroelectric energy, keeping the firm hydroelectric energy production for each system and/or as a whole system, and irrigation demand for the downstream areas.

Simulation was made in order to evaluate the rule curve for each reservoir, referring to the results of the MWRMP for the present condition. For the future development cases, simulation runs were carried out to maximize the overall hydroelectric energy generation, at the same time to meet the irrigation water demand within an allowable deficit by adopting a try and error method. The rule curves for the major reservoirs are illustrated on Fig. 1.3-3.

(2) Operation Rule for Irrigation Tanks

The simulation runs were performed to evaluate the rule curve to minimize diversion demands from the main system reservoirs and to make maximum use of local inflows, i.e. to minimize spillout from respective tanks, while at the same time, maintaining allowable irrigation reliability.

Every irrigation tanks have respective characteristics such as commanding area, its own catchment area, storage capacity, etc. As seen in Tables I.2.6 and I.2.8, almost all of the tanks have very limited tank capacity to irrigate its commanding area for about one-two months. High irrigation demand will be usually occur in May to August and November to February. Therefore, reservoir water level at end April and end October be kept at a certain level for the next irrigation water issues. Considering these fact and referring to the results of the MWRMP (Ref. 18), simulation runs were performed to fix the rule curve so as to minimize spillouts at respective tanks. The rule curves for major tanks are presented on Fig. I.3-3. b) Diversion Rule at Key Points

:

:

:

- Polgolla

The first priority is to release the river flow for firm energy demand for Ukuwela Power Plant and the second priority is given to the supply of additional released flows for downstream hydropower energy demands of the Mahaweli Ganga and downstream irrigation demands of each system.

Minipe

Elahera

_

••

Priority is given to the supply of diversion requirements for each system.

Kandukadu : The first priority is given to the supply of diversion requirements for System A and the second priority is to maintain the downstream river flow.

Priority is given to the supply of diversion requirements for each system.

(3)

1.4 WATER BALANCE STUDY

1.4.1 General

Assessment of available water resources under the present condition is essential for a future development plan. Moreover, the Polgolla diversion policy is of paramount importance and a key factor for the future development plan. As discussed in Section I.2.2 and ANNEX-H, there are three alternative transbasin conveyance systems, and two potential irrigation areas (NCRB and NWDZ). Taking into account these possible alternatives and future development plan, the water balance simulations were performed for the following cases:

| | Polgolla Diver | | | | sion | | |
|---------------------|----------------|---------|------|------|-----------|------|------|
| | | 875 MCM | | | 1,280 MCM | | |
| Conveyance System | A | В | C | D | | A | A |
| Simulation Run case | A145 | B151 | C145 | D109 | A118 | A209 | A242 |
| Irrigation Area | AMDP | AMDP | AMDP | AMDP | AMDP | AMDP | AMDP |
| | NCRB | NCRB | NCRB | · | NCRB | NCRB | NCRB |
| | NWDZ | NWDZ | NWDZ | _ | - | - | NWDZ |

The maximum possible irrigable areas were delineated by using the water balance simulation model and allowable deficit criteria for irrigation project, i.e. 80% probability in occurrence and 90% probability in quantity as adopted by the ID. The results are summarized in Tables I.4.1 and I.4.2, and illustrated on Figs. I.4-1 to I.4-8. The results of simulations are briefly described in succeeding Sections.

1.4.2 Procedure of Water Balance Simulation

Water balance simulation was carried out in the following procedures in order to provide the basic information for the alternative transbasin conveyance system study for the NCRB and NWDZ areas.

(1) Case D (Present case including the existing irrigation areas)

In order to grasp the availability of water resources for a future plan and the present reliability of irrigation water supply demands, the study was made on the present condition including the existing, under-construction and committed irrigation areas under the AMDP.

(2) Cases A, B and C with the combination of NWDZ+ NCRB for the screening of a transbasin conveyance system

In order to select a transbasin conveyance system for the NCRB area, the study for potential irrigation areas with the combination of NWDZ + NCRB was made by

taking into due consideration the economic comparison study. The comprehensive economic comparison study is described in detail in ANNEX-H.

(3) Based on the transbasin conveyance system selected in the above process (2) for NCRB area, the study was undertaken to select an appropriate combined case through the screening of development plans.

1.4.3 Water Balance Simulation under the Present Condition

Water balance simulation under the present condition including the existing, the under-construction and committed irrigation areas under the AMDP was carried out to grasp the availability of water resources for a future plan and the present reliability of irrigation water supply. The results of the simulation are summarized in Table I.4.1 and system flow diagrams for the present case are illustrated in Fig. I.4-4. As seen in the results, about 1,440 MCM at Minipe and about 4,850 MCM at the proposed Kandakadu intake site on the main stream of the Mahaweli Ganga, and about 720 MCM at Angamedilla on the Amban Ganga are wasted to the downstream or sea.

Keeping the river maintenance flow at the estuary, such surplus water will be utilized for the irrigation purposes. This surplus water is wasted mainly during the Maha season, because hydropower stations are generating electricity throughout the year by discharging water for a firm energy generation even in the Maha season. However, the irrigation demand in the Maha season is less; especially in March and April. It is possible to utilize this surplus water for irrigation purpose by providing regulating dams and tanks, and modifying the rule curve of a certain multipurpose dam.

In order to utilize the surplus water in the Maha season, there is a possibility to release water according to the irrigation demand, i.e. to relax the reservoir operation policy of the Randenigala power station to some extent.

Under the fixed Polgolla diversion policy, i.e. long term average of 875 MCM fixed by NEDECO, almost all of diverted water should be released to Systems H, IH and MH areas through the existing Bowatenna irrigation tunnel. Unless modification of the diversion policy at Polgolla and option to reduce a firm generation were permitted, there is no possibility to increase diversion water to Systems H and the NWDZ.

1.4.4 Water Balance Simulation for Future Case

(1)

) Water Balance Study for Future Case (Polgolla Diversion: 875 MCM)

Water balance simulations for a future case were performed to select an appropriate transbasin conveyance system among Case A, Case B and Case C. The results of the simulation are summarized in Tables I.4.1, and I.4.2 and illustrated on Figs. I.4-1 to I.4-8. The results of each case are summarized hereunder:

Case - A (New Alternative Plan):

Under a certain limitation of the Polgolla diversion to the Amban Ganga, a new conveyance canal parallel to the existing Minipe LB canal was planned to divert water from the existing the Minipe anicut (crest El. 114) to the Minneriya tank (FSWL: 93.7 m) crossing the Wasgamuwa National Park with minimum disturbance to the park. This diverted water to the Minneriya tank will be utilized for the existing System D1 and its expansion areas of the on-going Moragahakanda Project (about 740 MCM per annum) which would be originally irrigated by using water supplied from the Moragahakanda reservoir. About 760 MCM per annum at the Minneriya tank depending on the conveyance system selected will be pumped up to the NCP canal with a static head of 45-53 m.

The results of the simulation show that about 760 MCM out of about 1,480 MCM to be diverted to the Minneriya tank will be boosted up to the NCRB areas, and about 730 MCM of irrigation water originally supplied to System D1 from the ongoing Moragahakanda dam and about 250 MCM from the proposed Kalu Ganga dam will be supplied through a new NCP canal to the NCRB area.

The results indicate that increased diversion water to the NWDZ under the present Polgolla diversion policy (875 MCM) will be so difficult to keep the firm generation at the Bowatenna hydropower station (2 hrs peak operation) and the on-going Moragahakanda multipurpose project.

According to results of water balance study, possible diversion water through the Minipe RB canal was estimated at about 1,420 MCM per annum on an average (1949-1986). There is a certain possibility to divert about 240 MCM from the Maduru Oya reservoir to the Gallodai Aru basin, by using the existing Minipe RB canal and providing additional irrigation tunnel between Ulbitiya and Maduru Oya reservoirs. This diversion is subject to the future study.

Case - B (TDB Solution):

As discussed in Case A, about 1,510 MCM of surplus water at Minipe will be diverted to the NCRB areas. Possible irrigation area in the NCRB is the same as Case A. However since the Kalu Ganga dam is proposed and pumped water should be regulated. In this case, all diversion water should be pumped and static pumping head is about 85 m, and annual O&M costs for the pump station will be very high compared with Cases A and C.

As far as the water balance concerned, possible irrigable area in the study area will be similar to Case A with acceptable reliability of irrigation water supply.

Case - C (UNDP/FAO Solution):

Diversion water at Minipe will be led to Angamedilla then to the Kaudulla tank by gravity through the enlarged and extended existing Minipe LB canal. The results of simulation show that about 900 MCM out of 1,430 MCM diverted at Minipe will

be boosted up to the NCP canal, and about 530 MCM of irrigation water originally supplied to a part of System D1 from the on-going Moragahakanda dam and about 250 MCM from the proposed Kalu Ganga dam will be supplied to the NCRB area through the NCP canal within the allowable deficit.

Water Balance Study for Future Case (II) (Polgolla Diversion: 1,280 MCM)

(2)

Based on the economic comparison, Case-A was selected for the further detailed study to formulate an overall development plan stated in ANNEX-H. There is a certain possibility to irrigate the NWDZ and NCRB areas, by increasing the Polgolla diversion to the Amban Ganga, the NWDZ and NCRB, and by decreasing pumping water from the pump stations proposed in the respective alternative cases. Water balance simulation runs for the selected conveyance system of Case A under increased Polgolla diversion of 1,280 MCM per annum are carried out by the simulation model. The results of the study are summarized in Table 1.4.2 and the schematic flow diagramme are presented on Figs. I.4-6 and I.4-8.

As seen in Table I.4.2, increase of diversion water at Polgolla results in decrease of an average annual energy output especially on the existing hydropower stations on the Mahaweli main stream. Moreover, the irrigation deficit ratio is a little higher than that of the allowable deficit criteria.
