section will provide the basic information in determining the priority areas of protection from floods dealing in Annex VIII, Study on Flood Mitigation Plan.

Fig. V.4.2 depicts seven districts of Kota Bharu, Tumpat, Pasir Mas, Bachok, Machang, Tanah Merah and Kuala Krai in the study area. These seven districts include 48 sub-districts, which are the minimum unit to estimate flood damages.

4.3 Identification of Assets in the Probable Inundation Area

Assets vulnerable to floods are classified into two in the probable inundation area; agricultural and non-agricultural assets. Table V.4.1 shows the land use of the Kelantan State by district as of 1988. Judging from this, major crops planted are paddy, oil palm, rubber and tobacco, sharing more than 80% of total agricultural area, followed by coffee, maize, fruit and so forth.

Table V.4.2 shows the results of prediction by year 2010 for the land use in the whole of the Kelantan State (refer to Section 3.4 of Annex IV, Socio-economy). Four major crops of paddy, oil palm, rubber and tobacco are dominant by sharing 85% of total agricultural area in year 2010. The crops to share remaining 15% are vegetable, maize, fruit and so forth. Damages for the four major crops of paddy, tobacco, oil palm and rubber are estimated by counting acreage of them in the probable inundation area. On the other hand, damages for other crops such as vegetable, maize, fruit and so forth are estimated by multiplying the damage rate of these crops to paddy, which is referred to past studies, by the damage of paddy. The damage to livestocks is also estimated by multiplying the damage rate of livestocks to crops, which is referred to past studies. Thus, a total damage in the agricultural assets is computed by adding all the damages estimated above.

On the other hand, items to be raised as non-agricultural assets are residential houses including household effects, industrial, commercial and service establishments including building, equipment, inventory stocks, and public institutions such as hospitals, schools, mosques and government offices including building and equipment. Furthermore, infrastructures such as roads, bridges, irrigation facilities and so on are also estimated as the assets vulnerable to floods. The acreage of four major agricultural crops as well as the number of houses and establishment in the probable inundation area is summarized in Table V.4.3.

4.4 Establishment of Asset Distribution

The acreage and number of assets given in Table V.4.3 were first of all measured and counted by one metre in elevation using 1 to 25,000 scale topographic maps with a two-metre contour interval newly contoured in this study. The aim of this work is to grasp the relationship between the area-depth-duration and

distribution of assets. It is noted that elevation reading of assets by one metre was made by interpolating a two-metre contour interval of the topographic maps.

Following are assumed for measuring and counting the distribution of assets:

- Since 1 to 25,000 scale topographic maps with a 15-metre contour interval are not contoured with a two-metre interval in the areas for the 28 km long river stretches between Temangan and Kuala Krai (refer to Chapter 3 of Annex 1, Topographic Survey), the distribution of assets in these areas is basically measured and counted by evenly dividing the contour interval of 15-metre. However, some adjustments are given based on site survey.
- The topographic maps with a scale of 1 to 25,000 show the acreage of paddy and rubber. Since these maps were prepared before 1967, the acreage of paddy and rubber by each contour in the present condition is estimated by multiplying the increase rate of total acreage in a sub-district from 1967 to present by the acreage given by each contour in 1967.
- A sub-district (refer to Fig. V.4.2) is a minimum unit to summarize the acreage of assets.
- The planted areas of oil palm and tobacco are not shown on the 1 to 25,000 scale topographic maps, since those were rarely planted when the maps were prepared. Since tobacco is mainly cultivated together with paddy in the flat land and the plantation of oil palm spreads on the areas with undulation like rubber, the distribution of tobacco and oil palm by ground height is assumed to proportion to that of paddy and rubber by elevation in a sub-district, respectively.
- The distribution of industrial, commercial and service establishment and public institutions by ground height is assumed to proportion to population or the number of residential houses measured from the maps by elevation in a sub-district.

4.5 Preliminary Study on Socio-economic Condition in the Probable Inundation Area

The socio-economic activities in the probable inundation area are in prosperity along the Kelantan River with four major towns of Kota Bharu, Pasir Mas, Tanah Merah and Kuala Krai as a centre of activities, resulting in the concentration of population in these four towns including surrounding areas. Economic activities in these urban areas include the industrial, commercial and service sectors. The number of building and establishment in these sectors was already given by sub-district or by river stretch in Table V.4.3.

On the other hand, the rural areas in the probable

inundation area are sparsely populated, and people in these rural areas are engaged in agriculture. Main crops cultivated are represented by paddy, tobacco, rubber and oil palm. Paddy field spreads over almost all the districts, but the coastal regions of Kota Bharu, Tumpat, Pasir Mas and Bachok districts overwhelm other districts in planting area. On the other hand, rubber and oil palm are extensively planted in Pasir Mas district as well as Machang, Tanah Merah and Kuala Krai districts in the upstream areas of the Kelantan River.

4.5.1 Basic socio-economic conditions

Population in the probable inundation area was projected by sub-district for the period from present to year 2010 with an interval of 5 years as given in Table V.4.4, while Tables V.4.5 and V.4.6 show the results of projection for the population density and number of houses in the probable inundation area.

The number of industrial, and commercial and service establishments is forecasted as summarized in Tables V.4.7 and V.4.8 respectively, while social amenities such as medical, educational, religious and administrative institutions are estimated to increase as given in Table V.4.9 to V.4.12, respectively. Further details are discussed in Annex IV, Socioeconomy.

4.5.2 Agro-economic conditions

The increase of cultivating and planting areas for four major crops of paddy, tobacco, rubber and oil palm was projected in the probable inundation area by sub-district for the period from present to year 2010 with an interval of 5 years as given in Tables V.4.13 to V.4.16.

4.6 Estimate of Present and Future Unit Value of Assets and Damage Rate

The unit value of assets and their damage rate are estimated for assessing the flood damage of assets counted and measured in the probable inundation area in a monetary term. The unit price of assets is expressed in the price level of year 1988. The flood damage rate is obtained from the relationship between water depth and duration in flooding.

4.6.1 Unit value of assets

(1) Unit value for agricultural assets

Agricultural damages are classified into two losses; one is the loss of yield of crops and the other is loss of production due to mortalities of crops by flood. The unit values for the yield of paddy, tobacco, rubber and oil palm are given in Tables V.4.17 to V.4.20, respectively. The conversion rates of 3.2 and

8.5 ton/ha are applied to estimate the farm-gate prices of rice and tobacco per hectare, respectively, while the unit yield of rubber and oil palm varies by age of trees.

The production cost of paddy is estimated at M\$1,317 (=1,322.85 x 0.85 + 1,234.85 x 0.1 + 1,338.5 x 0.05) by taking the weighted average of production costs varied by varieties and planting methods as given in Table V.4.21. The production cost of tobacco is given in Table V.4.22. The accumulative production costs of rubber and oil palm, which are perennial trees, consist of initial and maintenance costs, which are estimated as given in Tables V.4.23 and V.4.24 respectively by assuming the economic life of 25 years for those trees.

(2) Unit value for non-agricultural assets

The unit value of residential houses, and industrial, commercial and service establishments, which are non-agricultural assets, is estimated in Table V.4.25 by referring to the results of interview at the Department of Public Works (JKR), Kelantan. Table V.4.26 shows the increase of unit value for the nonagricultural assets by year 2010.

4.6.2 Damage rate of assets

The damage rate for agricultural and non-agricultural damages was estimated by referring to the past studies in Malaysia. Tables V.4.27 and V.4.28 show the damage rate of paddy and tobacco, while the damage rates for rubber and oil palm include not only the ones for production losses, but also for yield losses. Tables V.4.29 and V.4.30 show the damage rates for the yield and production of rubber and oil palm including unit values. It is noted that the damage rates for rubber and oil palm are referred to the monitoring survey of damages for 1982-83 and February/March 1984-floods occurred in the Batu Pahat River basin of the Johor State under Western Johor Agricultural Development Project.

The damage rate of non-agricultural assets is estimated as given in Table V.4.31 by referring to National Water Resources Study, Malaysia and Regional Water Resources Study of South Johor.

5. PROBABLE FLOOD DAMAGE

5.1 Inundation Area - Flood Water Level - Flooding Duration Relationship

The inundation area, flood water level and flooding duration of 1967, 1983 and 1986-pattern flood were confirmed based on site interview by referring to the respective flood reports for estimating probable flood damages. The inundated area of 1986pattern flood with a 3-year return period extended to 510 km² as delineated in Fig.V.5.1, whilst 870 km² for the 1983-pattern flood with a 13-year return period as given in Fig.V.5.2 and 1,050 km² for the 1967-pattern flood with a 50-year return period as given in Fig.V.5.3.

Table V.5.1 summarizes the estimate for the flood water level and flooding duration of three selected floods. Flood water level was estimated by adding the ground level read from the 1 to 6,360 scale topographic maps to the flood water depth obtained from site interview and respective flood reports.

The flooding duration was also determined based on the flooding duration obtained from site interview and respective flood reports.

5.2 Probable Flood Damage

5.2.1 Items to evaluate the damage

Probable flood damage of 1967, 1983 and 1986-flood was evaluated on the following three items; that is,

(i) Agricultural damage

In the State of Kelantan, the areas of crops planted with the seasonal variation are for paddy and tobacco. Shown in Fig.V.5.4 are the cropping calendar of paddy and tobacco and the frequency of flood peak discharges beyond 5,000 m³/sec at Guillemard Bridge. Since the relatively high flood frequency of 72% was recorded on December, the damages of paddy and tobacco are assumed on the basis of the area planted on December. As for the planted areas of rubber and oil palm, they are constant throughout the year.

The damages for other crops except above major crops were evaluated multiplying the rate of damages of other crops to the damages of paddy. The rate of damages of other crops was estimated at 20% on an arithmetric average from the records in the flood reports as enumerated below:

(Unit:thousand M\$)

Gron		Flood Report	
Crop	1967-flood	1982-flood	1986-flood
Paddy	13,762	182	631
Tobacco	-	-	40
Rubber	7.5	3.6	5
Oil Palm			7
Others	574	65	118
Others/Paddy	48	36%	198

Remarks : A price level is set at recorded year.

Whilst the damages of livestocks were evaluated based on those magnitudes recorded in the flood reports taking the probability of flood into considerations as given in Table V.5.3.

(ii) Non-agricultural damage

The damage of infrastructures such as roads, bridges, irrigation facilities, electric power facilities, water supply facilities and other public facilities was evaluated at the ratio of 30% to the damages of houses and buildings considering the following condition:

Shown in Table V.2.6 are the recorded damages of infrastructures in the flood reports. These values, however, do not correspond to the magnitudes of recorded floods. Furthermore, the recorded damage does not cover the full range of flood damage. Whilst the in-depth survey of flood damage carried out in past in and around the Kelantan River basin as given in Table V.5.4 shows the ratio of damage to the infrastructures ranging from 30% to 50%. In this Study, the ratio of 30% in minimum was adopted.

(iii) Indirect damage

As well as the evaluation of non-agricultural damage, the indirect damage such as the suspension of production, trade, transportation and communications, and costs for rescue and relief activities was evaluated on the basis of the in-depth survey of flood damage as given in Table V.5.4. The ratio of 30% on an average to the direct damage was regarded as the indirect damage.

5.2.2 Probable flood damage

Submerged assets and flood damages at a price level of 1988 for the magnitude of selected floods were estimated as given in Tables V.5.5 and V.5.6 under the aforementioned assumptions respectively. The probable flood damages for various return periods of 5, 10, 15 and 20 years were interpolated on the basis

of the relationship between the damages of selected floods and thier return periods. Since none of damage is caused by the flood with the probability of once in two years, the annual mean flood damage exceeding the level of 2-year probability was estimated under the socio-economic conditions in 1988 as given in Table V.5.7. The probable flood damage was estimated to be 243 million M\$ for a scale of 50-year return period.

Table V.4.29 Unit Value and Flood Damage Rate for Mortality of Rubber and Oil Palm

Source: National Water Resources Study, Malaysia, Regional Water Resources Study of South Johor, Dec. 1985 Farm Budget, Kelantan SEPU Nov.1987

Note: The average value of loss by flood is assumed to be the sum of the total loss per hectare at each year of crop age divided by the total number of the years considered. It also assumes to be a mean distribution of crops of all ages in the crop field.

VI. REVIEW AND UPDATING OF WATER RESOURCES DEVELOPMENT PLAN

1. INTRODUCTION

The study objectives are mainly divided into following two aspects:

- (1) To review and update the previous plans for water use of the Kelantan River so as to determine the optimum reservoir scale for water resources development, and
- (2) To identify the potential damsites in the Kelantan River basin and carry out the engineering studies for dam structures.

The water resources development plan aims at searching water supply sources to cope with the incremental water demand in the target year of 2010, and also developing the hydropower potential to meet the growing electric power demand. In this connection, following were discussed in this Annex VI; (1) the present and future water demand of the Kelantan River, (2) the water demand and supply balance assuming subject to "without and with dam development scheme", and (3) the hydropower potential at the proposed three dam sites, Lebir, Dabong and Nenggiri.

Based on the above discussion, the study formed a conclusion on the optimum dam development scheme which is available to meet the water demand in 2010 and can provide the greatest benefit for hydropower generation. The results of study are finally incorporated into the overall plan of multi-purpose dam projects which include the functions of flood mitigation as well as water supply and hydropower generation.

VI - 1

2. EXISTING WATER USE OF THE KELANTAN RIVER

2.1 Irrigation Water Use

Water of the Kelantan River is at present used for four major irrigation schemes, i.e. Kemubu, Salor, Lemal and Pasir Mas, all of which stretch out in the lower reaches of the Kelantan River as shown in Fig. VI.2.1. These major irrigation schemes were developed by DID from 1951 to 1973 to increase the yield by double paddy cropping. Operation and maintenance were transferred to KADA after completion. The present irrigable areas for these schemes sum up to about 31,800 ha which requires about 72 m³/sec in maximum water use to realize the entire double cropping as shown in Table VI.2.1.

The water abstraction fully depends on the existing four pumping stations, all of which are located along the reaches downstream from Guillemard Bridge as illustrated in Fig.VI.2.1. The maximum capacity of the pumping stations was originally designed to be 52.9 m³/sec in total as shown in Table VI.2.2. However, due to the over-age pumping facilities, the pumping capacity has considerably decreased. According to the recent pump tests carried out by KADA, the present available capacity is estimated at about 35 m³/sec as referred to Table VI.2.2.

At present, the main season crop is usually planted in October/November and harvested by the end of March, while the off season crop is planted in April/May and harvested by September. Peak water demand required for the Kelantan River as a source occurs in May/June. Since the maximum irrigation demand is much larger than the existing available pumping capacity, the actual irrigated area has been limited within 60 to 70% of the total irrigable area both for main and off seasons as given in Table VI.2.3. Thereby, KADA implements the renovation of the existing pumping facilities as well as other irrigation facilities so as to realise the double cropping irrigation for the whole irrigable area by the end of 1990.

2.2 Domestic and Industrial Water Use

2.2.1 Maximum supply capacity

Groundwater was a sole water source for public supply system in the State of Kelantan by 1982. Thereafter, the Kelantan River and other surface flows were sought as water sources to solve the quantitative and qualitative restriction of the groundwater use and to cope with the rapid increment of domestic and industrial water demand.

The present maximum demand sums up to about 134 Mld in the lower reaches of the Kelantan River covering the districts of Kota Bharu, Tumpat, Pasir Mas, Machang, Bachok, Pasir Puteh and Kuala Krai. The said maximum demand is met by the groundwater (72 Mld), the Kelantan River (43 Mld) and other surface flows (19 Mld) as shown in Table VI.2.4. Water from the Kelantan River is abstracted from two existing pumping stations; one located at Kg. Kelar in Pasir Mas district with its pumping capacity of 22.70 Mld and the other at Sg. Kelantan in Tanah Merah district with its capacity of 20.43 Mld. These pumping stations are located along the Kelantan River downstream from Guillemard Bridge as illustrated in Fig. VI.2.1.

2.2.2 Daily average use of domestic water

The enlargement of maximum supply capacity starting from 1982 could increase the daily average domestic water supply from 39 Mld in 1980 to 76 Mld in 1985 as shown in Table VI.2.5. Daily average domestic water supply in 1985 corresponds to about 57% of maximum supply capacity. It is herein noted that the share of supply from the Kelantan River was nil in 1980 but increased to 24 Mld equivalent to 32% of total average supply in 1985.

With the increment of daily average water supply, the population covered by the public water supply system has expanded from 147,000 (coverage rate of 19.5% to total population) in 1980 to 230,000 (coverage rate of 25.6%) in 1985. In this connection, the per capita consumption rate is estimated at 137 l/day.person in 1980. The values in recent years would be higher, but could not be assessed due to lack of available data (refer to Table VI.2.5).

The estimated per capita consumption in 1980 is deemed to be rather low compared with the usual consumption rate of some 200 l/day.person. This low consumption rate will be attributed to the high supply loss as estimated at 48.7% in Table VI.2.5 and the inadequately small supply capacity before 1982. It is however anticipated that the supply loss is gradually reduced and that the per capita consumption rate increases from 1982 onward due to the recent high supply capacity system.

2.2.3 Potential use of industrial water

The potential use of industrial water in 1985 was estimated on the basis of following available information:

- The state gross industrial output as of 1985 expressed in monetary value, and
- Water use rate required to unit industrial output which was cited from the results of sampling survey carried out in the National Water Resources Study, 1982.

As shown in Table VI.2.6, the actual industrial output amounted to about M\$300 million in 1985. The corresponding potential water use in 1985 is estimated at 16 Mld.

Judging from the water supply system enlarged after 1982, most of present and future industrial water will be taken from the Kelantan River. In fact, as shown in Table VI.2.7, there are five major industrial estates in the State of Kelantan and the considerable part of their water use is projected to rely on the Kelantan River water.

2.2.4 Total amount of present domestic and industrial water use

Domestic and industrial water use is computed at about 92 Mld on an average in 1985; 76 Mld for domestic water use and 16 Mld for industrial water use. The said daily average water use corresponds to about 70% of the maximum supply capacity.

Water sources for the daily average use are classified as follows:

- The Kelantan River: 24 Mld for domestic water use and 16 Mld for industrial water use, and
- Other sources; 52 Mld.

As estimated above, the present water use taken from the Kelantan River is to be about 40 Mld which corresponds to about 90% of the maximum supply capacity abstracted from the Kelantan River.

VI - 4

3. FUTURE WATER DEMAND OF THE KELANTAN RIVER

3.1 Irrigation Water Demand

The future irrigation water demand for the source of Kelantan River is estimated in accordance with phasing development programmes of irrigation schemes. Thereby, the phasing development programmes are preliminarily assumed on the basis of the interview with the agencies concerned such as KADA and Kemasin-Semerak Project office, DID as well as the review on the previous study reports such as "KADA II Improvement Project, 1982" and "Kemasin-Semerak Integrated Rural Development Project, 1979". It is estimated as shown in Table VI.3.1 that the irrigation demand will increase from the present maximum use of 35 m³/sec to the peak demand of 85 m³/sec in 2010. It is herein noted that the future peak demand is assumed to occur on April from the result of the various study reports. The double cropping area of about 50,000 ha will be irrigated with maximum supply of 85 m³/sec in 2010 as referred in Table VI.3.1.

The development programmes herein assumed are enumerated as below:

(1) Improvement of existing KADA irrigation areas

The existing irrigable area of 31,800 ha will be entirely used for double paddy cropping by the end of 1990 by improving existing irrigation facilities. In this connection, KADA is executing the plan to either replace or rehabilitate the existing pumping facilities so as to increase the total pumping capacity from the present 35 m³/sec to about 43 m³/sec as referred to Table VI.2.2. Furthermore, a new pumping station with its capacity of about 37 m³/sec is to be constructed by DID in 1990 near the existing Kemubu pumping station. Accordingly, the total pumping capacity will reach about 80 m³/sec by 1990.

The peak water demand for the entire double cropping will be 72 m³/sec which comes out on April by assuming that a 40-day presaturation period starts on March 11th (refer to "KADA II Improvement Project").

(2) Kemasin irrigation scheme

The Kemasin irrigation scheme is currently being implemented under "Kemasin-Semerak Integrated Rural Development Project" and to be completed by 1990. The area of 3,775 ha in the scheme is irrigated by taking the Kelantan River water from the new Kemubu pumping station during the off season. The peak water demand is to be 5.4 m³/sec which comes out on May (refer to "Kemasin-Semerak Integrated Rural Development Project").

(3) Semerak irrigation scheme

Succeeding to the Kemasin irrigation scheme, the Semerak
