# The Khoua Khao storage pond

Storage volume (Compound section) 32,000 m<sup>3</sup>
Revetment works (Concrete block) 2,500 m
Nos. of bridge 10

The lateral canal (Saya Settathirath)

3 km

### 6.9 Construction Plan and Cost Estimate

## 6.9.1 Construction work of the Hong Ke system

The civil works to be constructed under the Project are broadly divided into two categories; the drainage facilities. and the retarding basin. The drainage facilities are further divided into two categories; the main drainages canal and the lateral canals. Main works for each category are listed as follows;

# (1) Main Drainage canal

- Khoua Khao Drainage canal
- Hong Thong Drainage canal
- Hong Ke Drainage canal

### (2) Lateral Canal

- Canal system along Say Setthathirath road

## (3) Retarding Basin

- Nong Chanh Retarding basin

## 6.9.2 Construction Schedule of the Hong Ke system

## (1) Project schedule

The target date for completion of the Project is assumed to be the end of 36th month. Approximately, 3 years would be required for the project work from the commencement of Engineering basic design to the

completion of construction work. The necessary periods are summarized as follows;

a) Engineering design including preparation

of tender documents for construction : 5.5 months

b) Prequalification and Tendering : 5.5 months

c) Main construction works : 24 months

Note: Civil works would constitute the critical path work of the Project; mobilization, site preparatory works and the improvement of the Hong Ke and Hong Thong. The lateral canal box culvert and the Hong Ke retarding basin are constructed in the first one (1) year and remaining construction works in the latter one (1) year.

### (2) Construction work schedule

Fig 6.10 shows the construction time schedule of the Project. Major works scheduled in each year are described below.

#### First year

- a) Award of main construction work contract
- b) Construction of temporary facilities for contractor use
- c) Construction of access road and haul road
- d) Care of water and dewatering
- e) Fascine hurdle with Sand bags (coffering)
- f) Excavation, embankment and slope protection works of the Hong Ke main drainage canal
- g) Excavation and concrete works of the Morning Market box culvert
- h) Excavation and concrete work of lateral canal

### Second Year

- a) Care of water and dewatering
- b) Fascine hurdle with sandbags (coffering)
- c) Excavation, embankment and slope protection works of the Khoua Khao and Hong Thong main drainage canal
- d) Excavation, embankment and slope protection works and related structure of the Nong Chanh retarding basin
- e) Finishing works

# 6.9.3 Construction Method

# (1) Main drainage facilities

The construction of the main drainage facilities will be mainly executed during the dry season when water level of the existing drainage canal is low. Care of water and dewatering will be carried out firstly and this will be immediately followed by a temporary fascine hurdle with sandbags (coffering) construction. Then excavation, embankment, slope trimming and slope protection works will follow thereafter.

Earth works for main drainage canals will be carried out mainly by a back hoe and bulldozers. Excavation of high water canal will be conducted by combination of swamp type bulldozers and Amphibious excavators. The trimming of canal side slopes will be made by back hoes or manual labors. The compaction for canal embankment will be carried out by vibration rollers after conditioning the fill materials to have a moisture content in the required range. The embankment materials will be obtained from suitable excavated materials in drainage canals, and/or the extracted from borrow-pits.

Revetment and sod facing works are also carried out by manual power mainly.

Bank protection work and structures with wet masonry will be carried out using a portable type concrete mixer as the supporting equipment to the manual construction.

### (2) Box Culvert

A combination works by manual power and a back hoe will be applied for this works. A portable type concrete mixer will be used for the concrete.

#### (3) Lateral Canal

The construction of lateral canal improvement will be carried out divided into several stages of the construction section in order to secure the drainage system during construction.

Based on the run-off discharge to the drainage canal and economical point of view, it is planned that the lateral canal improvement works should be carried out by the stepwise construction taking account of the site conditions. The works will be executed by two to three crews in a parallel way.

Excavation will be carried out by a back hoe and dump trucks for hauling works.

A portable type of concrete mixer will be provided for the small quantity of concrete of the lateral canal improvement works.

## (4) Nong Chanh Retarding Basin

The retarding basin construction works will be carried out by the stepwise construction in accordance with the site condition providing the partial coffering method using fascine hurdle with sand bags. The works will be executed by two to three crew in a parallel way.

The coffering material will be shifted to the next step construction

The construction works will be concentrated to the retarding basin in the dry season.

Excavation of high water portion will be conducted by the combination of a swamp type bulldozer, an amphibious excavators and dump trucks under the dry condition to be secured by partial coffering.

Fascine hurdle with sand bags for coffering will be provided mainly by manual power.

Excavated soil will be disposed to the spoil bank by dump trucks.

The trimming of side slopes will be made by back hoe or manual labor. The compaction for embankment will be carried out by a vibration roller after conditioning the fill materials to have a moisture content in the required range. The embankment materials will be obtained from the suitable excavated materials in canals, and/or the extracted from borrow-pits.

Stone or concrete block masonry works will be conducted by manual power mainly.

Revetment and sod facing works are also carried out by manual power mainly.

### (5) Metal Works

The installation of gate, screen and it's accessories will be conducted in later stage of construction works.

Installation will be conducted mainly by manual power. Truck crane will be utilized as the supporting equipment to manual work for installation of gates, screens and accessories.

### (6) Crossing Facilities

There are crossing utilities in the Vientiane city Intercepter such as power lines, water supply pipes and telephone lines.

Those facilities are planned to be replaced following to drainage canal works.

Required works for renewal will be conducted by the nominated contractors of each agencies.

#### 6.9.4 Cost Estimate

The main works of the Hong Ke system are excavation and embankment of earth, concrete block or the revetment works, concrete works for culvert and weir, sod facing for the bank protection, dry stone masonry for the bank protection, metal works for gates and the constructions of bridges. Meanwhile the main construction works for the improvement of the lateral canals are excavation of earth and concrete works. The work volumes thereof are estimated as summarized below:

# (1) Main Canal and Retarding Basin

Excavation	427,700	$m^3$
Embankment	32,900	$m^3$
Concrete block	22,210	$m^2$
Concrete works	8,550	$\dot{m}^3$
Metal works	82	ton
Sod facing	49,000	$m^2$
Stone masonry	1,700	$m^2$
Concrete pile	5,900	m
Reinforcement bar	541	ton
Asphalt pavement	25,950	$m^2$
Laterite pavement	10,100	$m^2$
Bridge (Concrete slab)	17	nos
Bridge (Metal girder)	4	nos

### (2) Lateral Canal

Excavation	44,100	$m^3$
Concrete	8,200	$m^3$

The estimated unit prices as described in Part 1 is applied to the work volumes estimated and the direct cost is thus estimated.

In addition to this, indirect costs are estimated. Indirect costs comprise the land acquisition cost, engineering service cost and government's administration cost including the operation, maintenance and repair costs. The land acquisition cost or the compensation costs were estimated on the basis of the area for the right-of-way and the unit price of land. The engineering service cost and the government's administration cost are estimated on manmonth basis to cover the costs of supervisions and management of the Project.

The financial costs thus estimated are summarized as follows;

	Item	Foreign (J. Yen) (1,000)	<u>Local</u> (US\$) (1,000)	<u>Total</u> (Equivalent) (US\$1,000)
(1)	Direct Cost			
	a) Hong Thong	128,802	694	1,607
	b) Khoua Khao	171,336	973	2,188
e. Te	c) Hong Ke	192,140	919	2,281
	d) Nong Chanh	150,736	907	1,976
	e) Box culvert	61,261	405	839
٠.	(Main works sub total)	704,275	3,898	8,891
	f) Lateral canal-1	77,849	436	987
	g) Lateral canal-2	137,881	919	1,898
. *	(Direct cost total)	920,005	5,253	11,778
(2)	Indirect Cost			
	a) Land acquisition	-	122	122
	b) Government's administration	-	271	271
	c) Engineering service	177,745	184	1,445
	d) O&M equipment	135,241		959
	(Indirect cost total)	312,986	577	2,797
(3)	Physical contingency	92,001	525	1,178
(4)	Grand total	1,324,992	6,355	15,753

(Current price as of October 1989)

## 6.10 Economic Evaluation

## 6.10.1 Conditions Adopted in the Evaluation

Several conditions are employed in this economic evaluation. The time basis for the estimations of benefit and cost are set at October 1989. The foreign exchange rates adopted are as follows;

Japanese Yen 100 = Kip 418 = US\$ 0.709

In other words, US\$1.0 is equivalent to Kip 590 or Yen 141.

The project life is assumed to be 50 year. The OMR cost after 2020 is assumed to be the same with that at present. The benefit after 2020 is assumed to increase in accordance with the growth of GRDP.

The improvement of the lateral and main drainage eventually entail an increase in the peak discharge to That Luang marsh with a water surface area of 1,000 ha. The increase is, however, minimized through providing the maximum storages in Nong Chanh retarding basin and the channel storages in the Hong Thong and the Khoua Khao. The flood might be further regulated by spilling out from the Hong Ke to the paddy field located along the right bank thereof. In this consequence, the adverse effect of the proposed plan to That Luang marsh is assumed to be insignificant.

# 6.10.2 Economic Benefit of the Drainage Improvement

The study on the inundation damage in the study area yielded the following proportions of damage in relation to the magnitudes of storms. Where the estimated damage to be incurred by 10-year storm is assumed 100;

2-year	storm	21
5-year	storm	86
10-year	storm	106
20-year	storm	114
50-year	storm	133

Since the main drainage is to be improved with the design discharge by 10-year storm and lateral drainage by 2-year storm, the damage reduction thereby is not always 100%. The analysis of the field survey yielded the following rates of damage reduction;

2-year	storm	100%
5-year	storm	72%
10-year	storm	48%
20-year	storm	38%
50-year	storm	25%

The figure indicates that if a 5-year storm occurs, 72% of potential damage is reduced but 28% of damage may remain.

According to the results of the damage analysis, a small storm, smaller than 2-year storm but brings about inundation damage to the area occurs 4 times a year on an average. The average damage incurred thereby is estimated to be 5% of one by 10-year storm.

The possible benefit of the drainage improvement is obtained as the expectation of the total damage reduction, the estimated average annual benefits by area and by year are presented in Table 2.14 upto the year 2040. The benefit of the Hong Ke system is obtained by the benefit of the sub areas, C, E, F, G and H.

The project is assumed to yield benefit after the completion of the main works. The damage reductions in the areas lower than El 168.0 m should be smaller than that in the areas above El. 168.0 m. The damage reduction thereof is assumed to be 20% of that in the area above El. 168.0 m.

# 6.10.3 Economic Cost of Drainage Improvement

The economic cost is estimated on the basis of the estimated financial cost. The methods adopted to the conversion are described below;

- (1) Foreign currency portion: The import tax of 5% is deducted.
- (2) Tradable goods: A conversion factor of 0.9 is applied.

- (3) Labour cost: A shadow wage rate of 0.37 and a conversion factor of 0.9 are applied.
- (4) Land acquisition cost for farm land: Production foregone estimated is applied.
- (5) Building: A conversion factor of 0.9 is applied.
- (6) Cost for the excavation at Nong Chanh marsh: The soils are utilized to the embankment. The respective conversion factors of 50% and 70% are applied.
- (7) The direct cost for the improvement of lateral canals are estimated by applying the unit cost of US\$24,000/ha to the urbanized area. The indirect cost is assumed to be 30% of the obtained direct cost.
- (8) The OMR cost is estimated to be 1% of the construction cost.

The cost for the main works are presented in Table 6.3. The costs for the improvement of lateral are summarized in Table 6.4.

# 6.10.4 Economic Internal Rate of Return (EIRR)

A cash flow for the Hong Ke system is prepared as shown in Table 6.5. The obtained EIRR is 7.3%,

## CHAPTER 7. SYSTEM FOR SUB-AREA L (NAM PASAK)

#### 7.1 Constraint

The improvement of the System for Sub-area I (Nam Pasak) comprises the channel improvement. The potential flood discharge for the 10-year storm rainfall is estimated assuming the projected land use in the year 2020. The estimated peak discharge is 23.3 m<sup>3</sup>/s in the lowest reach at the confluence with the Hong Xeng.

According to the hearing survey to the local people, the highest water level at the Dong Deng bridge on the Upstream Nam Pasak left branch in the recent 5 years is El. 167.5 m on the basis of the hydraulic analysis. level at the time at the confluence with the Nam Pasak is estimated to be El. The figure was confirmed referring to the water level recorded at the Consequently the design water level of the down-most reach of the gate site. Nam Pasak right branch is designated to be El. 167.2 m. The topographic survey and the damage survey carried out by the Study proved that the harmless water levels are El. 167.6 m at the confluence with the and El. 168.0 m at the upper-most reach of the Nam Pasak right branch. The river crosses some national highways and the main roads of the municipality. The surface elevations thereof are mostly around El. 169.0 m. The Nam Pasak should pass under these road with certain clearances. Fig. 7.1 shows the present condition of the System.

## 7.2 Alternative Drainage Plans

### (1) Alternative cases

The Nam Pasak meanders heavily. This might have been caused by the lack of riverbed slope. The recent flow direction which is reverse of the original one made the alignment further complicated. The meandering decreases its flow capacity to some extent. In view of this, short-cut was contemplated as one of the channel improvement. The short-cut stretches were selected with river morphologic tendencies, referring to the topographic map prepared in 1954. There are some portions where

short-cuts are recommended from the river morphologic viewpoint but cannot be provided in order to avoid possible social problems. Finally, five short-cuts were envisaged through the discussion with the Government. In the light of this, 2 (two) cases were adopted for the comparative study. One is the case to improve the existing channel and the other is the case with short-cuts. The proposed locations of short-cuts are shown in Fig. 7.2. The total canal length can be shortened by 30 per cent through the provision of the shortcuts.

Comparative study was carried out in terms of the cost which consists of the construction, maintenance and land acquisition.

## (2) Water level and bed elevation

In reference to the conditions mentioned above, the design flood water levels are designated. A uniform slope is contemplated for the drainage channel in view of the existing flat riverbed slope. And the elevations of channel beds at the strategic points were determined through interpolation of the existing river bed elevation of the upper-most reach and the lowest reach (Hong Xeng). Thereby a smooth profile is secured for the designed channel. The elevations determined are given as follows:

Car chair (n	nage Location	Design Max. Water Level (m)	Design Bed Elevation (m)	Observed Max. Water Level (m)	Present Bed Elevation (m)
Hong Xens	Į.				
HX/443	Sluice Gate	EL. 166.4	EL. 164.1	EL. 165.9	EL. 164.1
HX/736	Bridge of Route 13	EL. 166.7	EL. 164.2	EL. 166.0	
HX/3344	Confluence with Nam Pasak	EL. 167.2	EL. 164.4	EL. 166.5	EL. 164.4
Nam Pasal	<u>k</u>			•	
NP/0	Confluence with Hong Xeng	EL. 167.2	EL. 164.4	EL. 166.5	EL. 164.2
NP/3200	Confluence with Hong Thong	EL. 167.6	EL. 165.4	EL. 166.9	EL. 166.5
NP/4700	Close to Mekong	EL. 168.0	EL. 165.8	EL. 166.9	EL. 165.8

# 7.3 Design Flood Discharge for Alternative Drainage Plans

The following table summarizes the design flood discharges of the Nam Pasak-R at different stretches:

Peak discharge for Nam Pasak-R

Case/ stretch	5 7 4 0	
Original		·
0 - 1800	110	18.5
1800 - 3600	60	11.4
3600 - 4750	44	4.8
Case 1		
0 - 1920	152	23.3
1920 - 3220	62	6.8
Case 2		
0 - 1920	138	23.3
1920 - 4750	82	8.9

## 7.4 Flood Routing

Flood routing was carried out for the Nam Pasak with the assumptions given below:

- (1) Examination is carried out for the design discharge of 10-year discharge.
- (2) At the confluence of the Nam Pasak and Hong Xeng, the water level of El. 167.2 m in the Hong Xeng is adopted.
- (3) There are many bend portions in the river stretch of Nam Pasak. In case of the existing channel improvement, therefore, the bend loss as well as the friction loss is taken into consideration.
- (4) A revetment works of concrete block is assumed in the section of short cut. The coefficient of roughness of channel is assumed to be 0.025.

  Meanwhile sod facing is applied to the improvement of the existing channel. The side slope of 1 to 0.6 is adopted to the concrete block revetment works and 1 to 2.5 to the sod facing.

- (5) Because of the flat topography, a unique bed slope of 1 to 2,500 is assumed for the improved channel as shown in the figure.
- (6) Two different discharges are applied for the upstream reach and the downstream reach respectively.

The results of the routing are presented below:

		Alte	ernatives
Item	٠.	Case 1 (short-cut plan)	Case 2 (existing route plan)
Design discharge (m <sup>3</sup> /s)			
Upstream reach		6.8	8.9
Downstream reach		23.3	23.3
Water surface EL.(EL.m) at the upstream end of channel		168.0	168.0
Channel bottom width (m)		,	
Upstream reach		3.0	5.0
Downstream reach	-	7.0	8.0
River course length (m)			
Upstream reach		1,300	1,920
Downstream reach		1,920	2,830

## 7.5 Comparative Study

The comparative study was carried out in terms of the implementation cost for the 2 (two) alternatives for the Nam Pasak. In this cost estimation the following assumptions were employed.

- (1) The cost for principal works are estimated.
- (2) The excavation volume was estimated using the longitudinal profile and several cross-sections.
- (3) Maintenance road is necessary. The width thereof is 4.0 m.

- (4) The cost of bridge is estimated by applying a unit cost per square meter.

  All the existing bridges will be reconstructed. And the existing 5 (five) culverts crossing the main roads are replaced by new bridges.
- (5) The compensation cost for the relocated houses was estimated by counting the number of relevant houses. The price of house was estimated to be \$6,000/house. The land cost was estimated by the unit price of \$2.5/m<sup>2</sup> for residential area and \$1.0/m<sup>2</sup> for paddy field.
- (6) Maintenance cost is small and is neglected.

The estimated costs were tabulated as follows.

Unit: US\$1,000

Case	Low Channel	Čut	Maintenance Road	Bridge/ Culvert	Slope Facing	Land/House Compensation	Total
1 (Short cut)	966	409	234	919	804	226	3,558
2 (Existing)	1,425	693	387	940	162	0	3,607

As shown in the above table, the short-cut plan (Case 1) is more economical as compared with the improvement of the existing channel plan (Case 2). The cost of revetment work for the low flow channel can be reduced by the short-ning the total length. Judging from the economical point of view, the short-cut plan (Case 1) may be proposed to be the selected alternative.

# 7.6 Selection of the Conceptual Plans

The comparative study indicated that the improvement with short cut works is advantageous in view of economics and hydraulics.

The area of the proposed system is zoned from the environmental view points. The area along the upstream reach is identified to be the zone which should be reconstructed but the green area should be conserved as much as possible. Meanwhile the downstream reach is identified to be the zone which should be reconstructed to enhance the land use therein.

The plan with shortcut works will conform to the environmental zoning mentioned above. Green areas are to be conserved in the wide crescent channels in the upstream reach area which is identified to be green zone. On the other hand, the narrow channels of shortcut in the lower reach area save the space to develop for the reconstruction in the urban reconstruction zone.

In the light of this, the conceptual plan with shortcut is selected for the drainage improvement of the Nam Pasak.

# 7.7 Alternative Facility Plan

# 7.7.1 Conceivable Alternative Structure

The proposed plans comprise the existing channel and short cut. the structures related to the canal are section, revetment works and crossing structure. The proposed conceptual plan specify the hydrologic and hydraulic figures such as the design water level and design discharge at the strategic points of the proposed drainage structures.

Several conceivable types were compared for each structure. And subsequently the most suitable ones were adopted in the plan. In this connection, several conditions of the project sites were considered and referred to as follows;

- I) The topography is flat and the depth of channel is limited mostly to less than 3 meters and slope is less than 1 to some thousands.
- 11) Soils are mostly sandy clay and silt.
- III) The Study area is located in the center of the town.

  Accordingly the available land area is limited and yet the plan should produce good views.
- IV) The construction methods being adopted in the prevailing construction works in and around the Study area may be suitable method and materials to the local condition.
- V) The complicated operation and maintenance should be avoided.

In the light of the considerations mentioned above, the following types were adopted as the alternatives of each structure;

Channel ; Single section and compound section.

Revetment works; Sod facing, concrete block (2D), concrete block

(3D), concrete block 3D with finishing and Stone

masonry.

Crossing structure; Box culvert, pipe culvert, rigid frame bridge, RC

slab bridge and steel I-girder bridge.

In addition to the types given in the list, RC T-girder bridge is considered. However the girder, thereof is relatively deep and may not afford the sufficient clearance for the drainage channel. Consequently this type is discarded. A wood bridge is provided for private use if the existing one is to be demolished.

The technical features of each type are summarized as follows;

Single section : - Construction is simple.

- Work volume is comparatively small.

- The discharge of low flow is not smooth.

- Stage wise construction is not suitable.

Compound section: - The discharge of low flow is smooth.

- Multipurpose utilization of the high water

channel is possible.

- Suitable for stage wise construction.

- Work volume is large.

- Construction is slightly complicated.

Sod facing: - Domestic supply of material is possible.

- The coefficient of roughness is large (0.030 or

more).

- A gentle slope is required (1 to 3 or more).

Concrete block(2D): - The stability of slope can be controlled (1 to

0.3).

- Required concrete volume is small as compared

with the 3D-type.

- A wider channel is required as compared with the 3D-type.
- The coefficient of roughness is moderate (0.025).

Concrete block(3D): - The stability of slope can be controlled (1: 0.3).

- A width of channel can be the most narrow.
- The coefficient of roughness is small (0.020).
- Maintenance is easy.
- A considerable concrete volume is necessary.

## Concrete block(3D) With finishing

: Same as the type of concrete block (3D). The coefficient of roughness is small (0.015).

## Stone masonry

- : Domestic supply of material is possible.
  - Manual construction is necessary.
- Required slope is moderate (1 to 2).
- The coefficient of roughness is large (0.035).

### Box culvert and Rigid frame bridge

- : Girder is not necessary
  - Special foundation treatment is not necessary.
  - The required concrete volume is larger as compared with a concrete slab bridge.
  - The increase in the flow area is proportional to the increase in the water Level.

### Pipe culvert

- : Mostly be precast concrete made. The placing of concrete at site is difficult.
  - Accordingly a pipe culvert is suitable for only a small scale works.

# RC Slab bridge

- : Girder is not necessary.
  - Foundation works may be necessary.
  - The required concrete volume is small.

- The original river section therein can be secured.
- The span length should not exceed 10 meters.

Steel I-girder bridge

- : -A girder with a depth of less than 500 mm is available if the span length is less than 10 meters
- Foundation works may be necessary.
- The original river section therein can be secured.
- The construction cost is high.

# 7.7.2 Proposed Improvement of the System

The proposed improvement of the system comprised the existing Nam Pasak channel and the short cut channel proposed at the heavily meandering stretches. The design discharges thereof varies from the upstream reach to the downstream reach. The maximum discharge of 23.3 m<sup>3</sup>/s is for the lowest reach of the river. Meanwhile that in the upstream reach is 6.8 m<sup>3</sup>/s. Since the meandering is heavy, the width of the existing river varies from section to section. Some section have the width of more than 30 m. A corrugate pipe with a diameter of 900 mm is provided as a road crossing.

In accordance with the future land use plan, the river stretch is divided into the following two portions;

Stretch 1: From the origin to the crossing with Sam Sen Thai road (900 m)

Stretch 2: From the crossing with Sam Sen Thai road to the confluence with the Hong Xeng.

Since the area of the Nam Pasak is one of the most densely populated zone, the land acquisition is difficult. However the low flow must be discharged without any stagnation. In this accord, the compound section is considered throughout the channel. And in respect of the revetment works, the following three alternatives were examined;

Stretch	Channel	Case 1	Cases 2	Case 3
0				<del></del>
Stretch 1	Existing canal			
	HW channel	CB2D	SOD	SOD
	LW channel	CB3D	CB3D	CB3D
	Short cut portion			
	HW channel	CB3D	CB3D	CB3D
	LW channel	CB2D	CB2D	CB2D
Stretch 2	Existing canal		·	
	HW channel	CB2D	SOD	CB2D
	LW channel	CB3D	CB3D	CB3D
	Short cut portion			
	HW channel	CB3D	CB3D	CB3D
	LW channel	CB2D	CB2D	CB2D
		:		10.00

Where CB2D means a revetment work by concrete blocks for 2 dimensions. CB3D means a revetment work by concrete blocks for 3 dimensions. SOD means a revetment work by sod facing. The width of a shortcut portion is minimized by applying 3 dimensional revetment works in the high water channel.

All the cases are featured as follows;

- Case 1: The width of canal is small as compared with the alternative having sod facing portions.
  - The requisite concrete volume is large.
- Case 2: The requisite concrete volume is small.
  - The side slope is gentle and the right-of-way become large
  - Amenity spaces are provided.
  - The existing purification function of the river may be maintained.

Case 3: - The construction cost may be the medium of the case 1 and 2.

Applying the tentative unit prices, the construction costs for three cases are estimated. The results of the estimation is shown below;

Case 1 : US \$4.3 x  $10^6$  Case 2 : US \$3.3 x  $10^6$  Case 3 : US \$4.2 x  $10^6$ 

Case 2 yielded the least cost of US \$ 3.3 x.106

The green areas can be secured in the area along the stretch 1. However it might be difficult in the area along the stretch 2 in the shortcut portion. Sod facing is preferable to conserve a natural environment. Along this line, case 2 was adopted as the feasibility plan for the Nam Pasak.

The width of the channel is 6 to 9 meters at each crossing with road. Accordingly concrete slab bridge is proposed at all the crossings. The river crosses 7 roads in total.

The proposed cross section facility plan are illustrated in Fig. 6.7 and Fig. 6.8 together with the Hong Ke system. The proposed profile and cross sections are presented in Fig. 7.3.

# 7.7.3 Preliminary Features of Feasibility Plans

The comparative study for the Nam Pasak proved that the case 2 is the least costly alternative. The case improves the existing river channel with several shortcuts. In this case the high water channel of a shortcut is lined with sod facing to conserve the green area and to maintain the natural water purification function. The case is preferable from environmental point of view. The required land acquisition is mostly within the existing channel. Case 2 is the best alternative from both economical and environmental view points. Along this line, the case 2 is adopted for the feasibility plan.

The principal features of each feasibility plan are provisionally envisioned as presented below.

The Nam Pasak system

Design water level (Hong Xeng)

El. 167.2

Design discharge (max.)

23.3 m<sup>3</sup>/s

Design discharge (min.)

6.8 m<sup>3</sup>/s

Length of channel (compound)	3,220 m
Nos. of shortcut channel	5
Total length of shortcut channel	1,140 m
Width of shortcut (max)	10.4 m
Revetment works (concrete block)	6,440 m
Nos. of bridge	7

## 7.8 Construction Plan and Cost Estimate

## 7.8.1 Construction Schedule

The civil works to be constructed under the Project is the drainage facilities and the retarding basin. The drainage facilities are further divided into two categories; the main drainages canal and the lateral canals. Main works for each category are listed as follows;

(1)	Nam Pasak Main Drainage Canal	3,300 m
(2)	Lateral canal	1,800 m

The schedule for the works are considered as follows;

## (1) Project Schedule

The target date for completion of the System for Sub-area L is assumed to be the 36th month. Approximately, 3 years would be required for the improvement of the System from the commencement of engineering design to the completion of construction work. The necessary periods are summarized as follows;

a )	Engineering design including preparation of		
	tender documents, and prequalification :	6	months
b)	Tendering :	6	months
<b>c</b> )	Main construction works :	24	months

## (2) Construction Work Schedule

Fig. 7.4 shows the proposed construction schedule of the Nam Pasak System. Major work scheduled in each year are described below.

## The First Year

- a) Signing of Exchange Notes
- b) Selection and contract of consultant
- c) Detailed design and preparation of tender document
- d) Advertising
- e) Prequalification
- f) Tendering and evaluation of civil works

### The Second Year

- a) Award of main construction work contract and mobilization
- b) Construction of temporary facilities for contractor use
- c) Construction of access road and haul road
- d) Care of water and dewatering
- e) Fascine hurdle with sand bags (coffering)
- f) Excavation, embankment and slope protection work of the Nam Pasak main drainage canal
- g) Excavation and concrete work of lateral canal

## The Third Year

- a) Care of water and dewatering
- b) Fascine hurdle with sand bags (coffering)
- c) Excavation, embankment and slope protection work of the Nam Pasak main drainage canal
- d) Excavation and concrete work of lateral canal
- e) Finishing works

#### 7.8.2 Construction Method

## (1) Main Drainage Facilities

The construction of the Nam Pasak main drainage canal will be started at after completion of access road. Excavated soil will be conveyed by dump trucks and partly by utilized for embankment. the rest of them will be deposited into the old channel (short cut portion), which has an enough capacity to receive the soil from excavation.

The construction of the main drainage facilities will be mainly executed during the dry season when water level of the existing drainage canal is low. Care of water and dewatering will be carried out firstly and this will be immediately followed by a temporary fascine hurdle with sand bags (coffering) construction, then excavation, embankment, slope trimming and slope protection works will follow thereafter.

Earth works for main drainage canals will be carried out mainly by a back hoe and bulldozers. Excavation of high water canal will be conducted by combination of swamp type bulldozers and/or Amphibious excavators. The trimming of canal side slopes will be made by back hoes or manual labors. The compaction for canal embankment will be carried out by vibration rollers after conditioning the fill materials to have a moisture content in the required range. The embankment materials will be obtained from suitable excavated materials in drainage canals, and/or the extracted from borrow-pits.

Stone or concrete block masonry works will be conducted by manual power mainly.

Revetment and sod facing works are also carried out by manual power mainly.

Bank protection work and structures with wet masonry will be carried out using a portable type concrete mixer as the supporting equipment to the manual construction.

#### (2) Lateral Canal

The construction of lateral canal improvement will be carried out divided into several stages of the construction section in order to secure the drainage system during construction.

Based on the run-off discharge to the drainage canal and economical point of view, it is planned that the lateral canal improvement works should be carried out by the stepwise construction taking account of the site conditions. The works will be executed by two to three crews in a parallel way.

Excavation will be carried out by a back hoe and dump trucks for hauling works.

A portable type of concrete mixer will be provided for the small quantity of concrete of the lateral canal improvement works.

## (3) Crossing Facilities

There are crossing utilities in the Vientiane city Intercepter such as power lines, water supply pipes and telephone lines.

Those facilities are planned to be replaced following to drainage canal works.

Required works for renewal will be conducted by the nominated contractors of each agencies.

#### 7.8.3 Cost Estimate

The main works of the System for Sub-area L are excavation and embankment of earth, concrete block for the revetment works, concrete works for culvert, sod facing for the bank protection and the constructions of bridges. Meanwhile the main construction works for the improvement of the lateral canals are excavation of earth and concrete works. The work volumes thereof are estimated as summarized below;

# (1) Main Canal and Retarding Basin

$122,850 \text{ m}^3$
$10,770 \text{ m}^3$
$31,300 \text{ m}^2$
$3,020 \text{ m}^3$
126 ton
3,530 m
53,000 m <sup>2</sup>
14,900 m <sup>2</sup>

Laterite	e pavemei	it 💮	٠	٠.	6,500	$m^2$
Bridge	(Concrete	slab)			7	nos

### (2) Lateral Canal

Excavation  $14,200 \text{ m}^3$  Concrete  $2,640 \text{ m}^3$ 

The estimated unit prices as described in Part 1 is applied to the work volume estimated and the direct cost is estimated.

In addition to this, indirect costs are estimated. Indirect costs comprise the land acquisition cost, engineering service cost and government's administration cost including the operation, maintenance and repair costs. The land acquisition cost or the compensation costs were estimated on the basis of the area for the right-of-way and the unit price of land. The engineering service cost and the government's administration cost are estimated on manmonth basis to cover the costs of supervisions and management of the Project.

The financial costs thus estimated are summarized as follows:

·	Titem	Foreign (¥1,000)	Local (US\$1,000)	Total Equivalent) (US\$1,000)
(1)	Direct Cost			
	a) Nam Pasak	313,903	2,440	4,666
	(Main works sub total)	313,903	2,440	4,666
	b) Lateral canal	51,183	321	684
	(Direct cost total)	365,086	2,761	5,350
(2)	Indirect Cost			
	a) Land acquisition	-	226	226
	b) Government's administration		124	124
	c) Engineering service	69,897	96	592
	d) O&M equipment	98,559	•	699
	(Indirect cost total)	168,456	446	1,641
(3)	Physical contingency	36,500	276	535
(4)	Grand total	570,042	3,483	7,526

(Current price as of October 1989)

# 7.9 Economic Evaluation

## 7.9.1 Conditions Adopted in the Evaluation

Several conditions are employed in this economic evaluation. the time basis for the estimations of benefit and cost are set at October 1989. The foreign exchange rate adopted are as follows;

Japanese Yen 100 = Kip 418 = US\$ 0.709

In other word, US\$1.0 is equivalent to Kip 590 or Yen 141.

The project life is assumed to be 50 year. The OMR cost after 2020 is assumed to be the same with that at present. The benefit after 2020 is assumed to increase in accordance with the growth of GRDP. The peak discharge of the Nam Pasak increases as the consequence of the improvement. The paddy field

of 400 ha may absorb the increased inflow to the Hong Xeng. Accordingly the adverse effects of the improvement to the Hong Xeng and the Makhiao supposed to be insignificant.

# 7.9.2 Economic Benefit of the Drainage Improvement

The study on the inundation damage in the study area yielded the following proportions of damage by the magnitudes of storms. Where the estimated damage to be incurred by 10-year storm is assumed 100;

2-year	storm		21
5-year	storm		86
10-year	storm		106
20-year	storm	**	114
50-year	storm		133

Since the main drainage is to be improved with the design discharge by 10-year storm and lateral drainage by 2-year storm, the damage reduction thereby is not always 100%. The analysis of the field survey yielded the following rates of damage reduction;

2-year	storm	100%
5-year	storm	72%
10-year	storm	48%
20-year	storm	38%
50-year	storm	25%

The figure indicates that if a 5-year storm occurs, 72% of potential damage is reduced but 28% of damage may remain.

According to the results of the damage analysis, a small storm, smaller than 2-year storm which bring about inundation damage to the area occurs 4 times a year on an average. The average damage incurred thereby is estimated to be 5% of one by 10-year storm.

The possible benefit of the drainage improvement is obtained as the expectation of the total damage reduction, the estimated average annual

benefits by area and by year are presented in Table 2.14 upto the year 2040. The benefit of the Nam Pasak system is obtained by the benefit of the sub area L.

The project is assumed to yield benefit after the completion of the main works. The damage reductions in the areas lower than El. 168.0 m should be smaller than that in the areas above El. 168.0 m. The damage reduction thereof is assumed to be 20% of that in the area above El. 168.0 m.

# 7.9.3 Economic Cost of Drainage Improvement

The economic cost is estimated on the basis of the estimated financial cost. The methods adopted to the conversion are described below;

- (1) Foreign currency portion: The import tax of 5% is deducted.
- (2) Tradable goods: A conversion factor of 0.9 is applied.
- (3) Labour cost: A shadow wage rate of 0.37 and a conversion factor of 0.9 are applied.
- (4) Land acquisition cost for farm land: Production foregone is applied.
- (5) Building: A conversion factor of 0.9 is applied.
- (6) Cost for the excavation in the shortcut of the Nam Pasak: The soils are utilized to the embankment. The respective conversion factors of 50% and 70% are applied.
- (7) The direct cost for the improvement of lateral canals are estimated by applying the unit cost of US\$24,000/ha to the urbanized area. The indirect cost is assumed to be 30% of the obtained direct cost.
- (8) The OMR cost is estimated to be 1% of the construction cost.

The cost for the main works are presented in Table 7.1. The costs for the improvement of lateral canals are summarized in Table 6.4.

## 7.9.4 Economic Internal Rate of Return (EIRR)

A cash flow for the System for Sub-area L is prepared as shown in Table 7.2. The obtained EIRR is 4.2%.

# CHAPTER 8. SYSTEM FOR SUB-AREA I (HONG KAI KEO)

# 8.1 Conditions and Design Drainage

The Hong Kai Keo drains the subarea I. The catchment area thereof is 2.76 km<sup>2</sup>. The length of the river channel is 1,300 m with the average widths of 6 to 9 m. The slope of the existing channel is estimated to be 1 to 900. The river emanate from a marsh area named Nong Bon. The water area of Nong Bon is about 9 ha. According to the urban plan of the municipality, an area of 4 ha thereof is to be reclaimed for residential use. The remaining 5 ha is to be conserved as water area. This conserved area is proposed to utilize for the retarding basin.

The Hong Xeng has marked the flood water level of El. 166.7 m at the bridge of the No. 13 highway. the water level of El. 166.9 m is obtained at the confluence of the Hong Xeng and the Hong Kai Keo on the basis of the water level at the bridge. The elevations of the lands located along the Hong Kai Keo are mostly El. 166.0 to El. 167.0 and presently utilized for paddy cultivation. The area is susceptible to inundation. According to the urban plan of the municipality, the area is to be urbanized by the year 2000. In this drainage plan it is assumed that the land is elevated to El. 168.0 when it is reclaimed for the urbanization like other reclaimed lands along the national highway No. 13. Accordingly it is assumed that the harmless water level of Nong Bon is El. 167.5 m with head of about 60 cm from the confluence.

Another assumption was employed with regard to the urbanization. The land reclamation provides lateral drainage canals in the area. Consequently the runoff from the area is estimated by means of the rational method.

The operational depth of 1.0 m is assumed for the proposed Nong Bon regarding basin. The effective space of the basin for the retarding in thus assumed to be 50,000 m<sup>3</sup>.

Along this line, the design discharges were proposed for both Nong Bon retarding basin and the Hong Kai Keo. The proposed are summarized as presented below;

Design Flood Discharge of Hong Kai Keo

Canal, pond chainage	Catchment (ha)	Design discharge (m <sup>3</sup> /s)
Nong Bon Pond		
Outlet	160.8	16.8
Hong Kai Keo		
НКК 840 - 1,340 НКК 0 - 840	32.8 31.2	20.2 23.5

# 8.2 Drainage System

The flood water level of Nong Bon is set at El. 167.5 m as the elevation of the circumference land is El. 168.0. The low water level of the retarding basin is designated to be El. 166.5 m so that a flood control space of 50,000 m<sup>3</sup> is secured. At the outlet of the retarding basin a concrete weir is provided. The weir is free over flow type with sand flush gates. The crest elevation of the weir is set at El. 167.0 m with stoplog. The sill of the stoplog is set at El. 166.5 m so that the water surface could keep the elevation of El. 166.5 m in the ordinary case. If the water level of the Hong Xeng is anticipated to rise upto more than El. 166.5 m, the stoplog is closed to prevent the intrusion of the backwater. Thereby the flood control space of 50,000 m<sup>3</sup> is secured. The case may occur once in a few years. The basin impounds water permanently and allows multipurpose use to the local people.

The bed elevation of the Hong Kai Keo is El. 164.5 m at the lowest reach of the channel. The elevation coincides with the bed elevation of the Hong Xeng at the confluence. Meanwhile the channel bed slope of 1:1,300 is adopted on the basis of the existing channel profile. The bed elevation is set at El. 165.5 m at the uppermost section.

The compound section is contemplated for the Hong Kai Keo. The low flow section has the dimensions of 2 m wide and 0.5 m deep. The side slope of the low flow channel is 1 to 0.3 and a concrete block revetment works is provided. The bed width of the high water channel is 6 m. The side slope

thereof is 1 to 2.5 and is protected by sod facing. The typical section and the profile of the Hong Kai Keo is presented in Fig. 8.1.

On the left bank of the Hong Kai Keo, a maintenance road is provided. The width of the road is 5 m and is paved with asphalt. The road crosses several lateral canals. The largest on is located at about 1,000 m upstream from the confluence. A box culvert with a section of 1 m wide and 1 m deep is provided to cross he inspection road. Other lateral canals are connected to the Hong Kai Keo though concrete pipe culverts with a diameter of 600 mm embedded under the inspection road. The numbers of pipe culvert tally 10.

The Hong Kai Keo crosses Nong Soan Tho road and Phong Sa Ath road. A box culvert is provided at the former crossing and a wooden bridge is provided at the latter. Both crossing structures are to be demolished. A concrete slab bridge is to be constructed for the bridges. The width of Nong Soan Tho bridge is 4 m and designed for TL-14. The new bridge of Phong Sa Ath has the width of 2 m. The bridge is good for pedestrian and motor cycle.

# 8.3 The Principal Features of the System for Sub-area I

The System for Sub-area I comprises a channel improvement, a retarding basin and an inspection road. The woks incidental to the drainage improvement are two bridges and culvert to cross the inspection road. The principal features of the system are presented below;

## Design water level:

The Hong Xeng	·	El. 166.9 m
Nong Bon retarding l	basin (FWL)	El. 167.5 m
Nong Bon retarding t	basin (LWL)	El. 166.5 m

# The Hong Kai Keo canal:

Design discharge (Downstream)	$20.2 \text{ m}^3/\text{s}$
Design discharge (Upstream)	$23.5 \text{ m}^3/\text{s}$
Length	1,300 m
Bed slope	1:1,300
Width (channel bed)	6 m

Bank slope		1:2.5
Low flow channel (W >	: H m <sup>2</sup> )	$2.0 \times 0.5 \text{ m}^2$

Nong Bon retarding basin

Water surface area 50,000 m<sup>2</sup>
Flood control space 50,000 m<sup>3</sup>
Concrete weir crest el. El. 167.0
Concrete weir length 20 m

Flush gate Sluice 1 m x 1.5 m x 1 leaf

Stoplog width 4 m

Maintenance road

Width 5 m
Pavement Asphalt

Road crossing culvert 1 m x 1 m

Road crossing concrete pipe Dia. 600 mm

Bridge

Nong Soan Tha road type Concrete slab width 4 m load TL-14

Phong Sa Ath road type Concrete slab

width 2 m

# 8.4 Construction Plan and Cost Estimate for the System for Sub-area I

### 8.4.1 Construction Schedule

The civil works to be constructed under the Project are broadly divided into two categories; the drainage facilities and the retarding basin. The drainage facilities are further divided into two categories; the main drainages canal and the lateral canals. Main works for each category are Hong Kai Keo Main Drainage Canal of 1,270 m and Nong Bon Retarding Basin of 5 ha.

The schedule for the works are considered as follows;

## (1) Project Schedule

The target data for completion of the System for Sub-area I is assumed to be the 24th month. Approximately, 2 years respectively would be required for the Hong Kai Keo system work from the commencement of Engineering detailed design to the completion of construction work. The necessary periods are summarized as follows;

a) Engineering design including preparation of tender documents, and prequalification

6 months

b) Tendering

6 months

c) Main construction works

24 months

### (2) Construction Work Schedule

Fig. 8.2 shows the proposed construction schedule of the System for Subarea I. Major works scheduled in each year are described below.

# The First Year

- a) Signing of Exchange Notes
- b) Selection and contract of consultant
  - c) Detailed design and preparation of tender document
  - d) Advertising
  - e) Prequalification
  - f) Tendering and evaluation of civil works

### The Second Year

- a) Award of main construction work contract and mobilization
- b) Construction of temporary facilities for contractor use
- c) Construction of access road and haul road
- d) Care of water and dewatering
- e) Fascine hurdle with sand bags (coffering)
- f) Excavation, embankment and slope protection work of the Hong Kai Keo main drainage canal
- g) Excavation and concrete work of lateral canal for area I

### The Third Year

- a) Care of water and dewatering
- b) Fascine hurdle with sand bags (coffering)
- c) Excavation and concrete work of lateral canal
- d) Excavation, embankment and slope protection work of the Nong Bon retarding basin
- e) Finishing works

### 8.4.2 Construction Method

### (1) Main Drainage Facilities

The construction of the Hong Kai Keo main drainage canal will be started at after completion of access road. Excavated soil will be conveyed by dump trucks and partly by utilized for embankment. the rest of them will be deposited into the old channel (short cut portion), which has an enough capacity to receive the soil from excavation.

The construction of the main drainage facilities will be mainly executed during the dry season when water level of the existing drainage canal is low. Care of water and dewatering will be carried out firstly and this will be immediately followed by a temporary fascine hurdle with sand bags (coffering) construction, then excavation, embankment, slope trimming and slope protection works will follow thereafter.

Earth works for main drainage canals will be carried out mainly by a back hoe and bulldozers. Excavation of high water canal will be conducted by combination of swamp type bulldozers and/or Amphibious excavators. The trimming of canal side slopes will be made by back hoes or manual labors. The compaction for canal embankment will be carried out by vibration rollers after conditioning the fill materials to have a moisture content in the required range. The embankment materials will be obtained from suitable excavated materials in drainage canals, and/or the extracted from borrow-pits.

Stone or concrete block masonry works will be conducted by manual power mainly.

Revetment and sod facing works are also carried out by manual power mainly.

Bank protection work and structures with wet masonry will be carried out using a portable type concrete mixer as the supporting equipment to the manual construction.

### (2) Lateral Canal

The construction of lateral canal improvement will be carried out divided into several stages of the construction section in order to secure the drainage system during construction.

Based on the run-off discharge to the drainage canal and economical point of view, it is planned that the lateral canal improvement works should be carried out by the stepwise construction taking account of the site conditions. The works will be executed by two to three crews in a parallel way.

Excavation will be carried out by a back hoe and dump trucks for hauling works.

A portable type of concrete mixer will be provided for the small quantity of concrete of the lateral canal improvement works.

### (3) Nong Bon Retarding Basin

The regarding basin construction works will be carried out by the stepwise construction in accordance with the site condition providing the partial coffering method using fascine hurdle with sand bags. The works will be executed by two to three crew in a parallel way.

The coffering material will be shifted to the next step construction.

The construction woks will be concentrated to the retarding basin in the dry season.

Excavation of high water portion will be conducted by the combination of a swamp type bulldozer, an amphibious excavators and dump trucks under the dry condition to be secured by partial coffering.

Fascine hurdle with sand bags for coffering will be provided mainly by manual power.

Excavated material will be disposed to the spoil bank by dump trucks.

The trimming of side slopes will be made by back hoe or manual labor. The compaction for embankment will be carried out by a vibration roller after conditioning the fill materials to have a moisture content in the required range. The embankment materials will be obtained from the suitable excavated materials in canals, and/or the extracted from borrow-pits.

Stone or concrete block masonry works will be conducted by manual power mainly.

Revetment and sod facing works are also carried out by manual power mainly.

### (4) Metal Works

The installation of gate, screen and its accessories will be conducted in later stage of civil construction works.

Installation will be conducted mainly by manual power. Truck crane will be utilized as the supporting equipment to manual work for installation of gates, screens and accessories.

### (5) Crossing Facilities

There are crossing utilities in the Vientiane city Intercepter such as power lines, water supply pipes and telephone lines.

Those facilities are planned to be replaced following to drainage canal works.

Required works for renewal will be conducted by the nominated contractors of each agencies.

### 8.4.3 Cost Estimate

The main works of the Hong Kai Keo system are excavation and embankment of earth, concrete block for the revetment works, concrete works for culvert and weir, sod facing for the bank protection and the constructions of bridges. Meanwhile the main construction works for the improvement of the lateral canals are excavation of earth and concrete works. The work volumes thereof are estimated as summarized below;

### (1) Main Canal and Retarding Basin

1,700	$m^3$
3,600	$m^3$
5,800	$m^2$
1,210	$m^3$
1	set
000,0	$m^2$
,220	$m^3$
2	nos
570	m
46	ton
,340	$m^2$
2,600	$m^2$
	3,600 5,800 1,210 1 0,000 1,220 2 570 46 5,340

### (2) Lateral Canal

Excavation	43,120	$m^3$
Concrete	8,000	$m^3$

The estimated unit prices as described in Part 1 is applied to the work volume estimated and the direct cost is estimated.

In addition to this, indirect costs are estimated. Indirect costs comprise the land acquisition cost, engineering service cost and government's

administration cost including the operation, maintenance and repair costs. The land acquisition cost or the compensation costs were estimated on the basis of the area for the right-of-way and the unit price of land. The engineering service cost and the government's administration cost are estimated on manmonth basis to cover the costs of supervisions and management of the Project.

The financial costs thus estimated are summarized as follows;

<u>.</u>		Item	Foreign (¥1,000)	Foreign (US\$1,000)	Total (Equivalent) (US\$1,000)
(1)	Dire	ect Cost			
	a )	Hong Kai Keo canal	70,675	621	1,122
	b)	Nong Bon retarding basin	71,903	390	899
		(Main works sub total)	142,578	1,011	2,021
	b)	Lateral canal	158,343	996	2,119
		(Direct cost total)	300,921	2,007	4,140
2)	Indi	rect Cost			
	a )	Land acquisition	•	-	_
	b)	Government's administration		96	96
	c)	Engineering service	57,163	70	475
	d)	O&M equipment	· · · · · · · · · · · · · · · · · · ·	334	334
		(Indirect cost total)	57,163	500	905
3)	Phys	sical contingency	30,092	200	413
1)	Gran	d total	388,176	2,707	5,458

(Current price as of October 1989)

### 8.5 Economic Evaluation

### 8.5.1 Conditions Adopted in the Evaluation

Several conditions are employed in this economic evaluation. the time basis for the estimations of benefit and cost are set at October 1989. The foreign exchange rate adopted are as follows;

Japanese Yen 100 = Kip 418 = US \$ 0.709

In other word, US\$1.0 is equivalent to Kip 590 or Yen 141.

The project life is assumed to be 50 year. The OMR cost after 2020 is assumed to be the same with that at present. The benefit after 2020 is assumed to increase in accordance with the growth of GRDP. The peak outflow from the Hong Kai Keo to the Hong Xeng may increase as a consequence of the improvement. However the increase is minimized through the provision of Nong Bon retarding basin with a regulating space of 50,000 m<sup>3</sup>. Further the paddy fields with an area of 400 ha located along the Hong Xeng and the Hong Kai Keo have regulating functions. In this consequence, the adverse effect of the improvement to the Hong Xeng is considered to be insignificant.

### 8.5.2 Economic Benefit of the Drainage Improvement

The study on the inundation damage in the study area yielded the following proportions of damage by the magnitudes of storms. Where the estimated damage to be incurred by 10-year storm is assumed 100;

2-year	storm	21
5-year	storm	86
10-year	storm	 106
20-year	storm	114
50-year	storm	133

Since the main drainage is to be improved with the design discharge by 10-year storm and lateral drainage by 2-year storm, the damage reduction

thereby is not always 100%. The analysis of the field survey yielded the following rates of damage reduction;

2-year	storm	100%
5-year	storm	72%
10-year	storm	48%
20-year	storm	38%
50-year	storm	25%

The figure indicates that if a 5-year storm occurs, 72% of potential damage is reduced but 28% of damage may remain.

According to the results of the damage analysis, a small storm, smaller than 2-year storm which bring about inundation damage to the area occurs 4 times a year on an average. The average damage incurred thereby is estimated to be 5% of one by 10-year storm.

The possible benefit of the drainage improvement is obtained as the expectation of the total damage reduction, the estimated average annual benefits by area and by year are presented in Table 2.14 up to the year 2040. The benefit of the Hong Kai Keo system is obtained by the benefit of the Subarea I.

The project is assumed to yield benefit after the completion of the main works. The damage reductions in the areas lower than El. 168.0 m should be smaller than that in the areas above El. 168.0 m. The damage reduction thereof is assumed to be 20% of that in the area above El. 168.0 m.

### 8.5.3 Economic Cost of Drainage Improvement

The economic cost is estimated on the basis of the estimated financial cost. The methods adopted to the conversion are described below;

- (1) Foreign currency portion: The import tax of 5% is deducted.
- (2) Tradable goods: A conversion factor of 0.9 is applied.
- (3) Labour cost: A shadow wage rate of 0.37 and a conversion factor of 0.9 are applied.

- (4) Land acquisition cost for farm land: Production foregone is applied.
- (5) Building: A conversion factor of 0.9 is applied.
- (6) The direct cost for the improvement of lateral canals are estimated by applying the unit cost of US\$24,000/ha to the urbanized area. The indirect cost is assumed to be 30% of the obtained direct cost.
- (7) The OMR cost is estimated to be 1% of the construction cost.

The cost for the main works are presented in Table 8.1. The costs for the improvement of lateral are summarized in Table 6.4.

### 8.5.4 Economic Internal Rate of Return (EIRR)

A cash flow for the System for Sub-area I is prepared as shown in Table 8.2. The obtained EIRR is 3.5%.

### CHAPTER 9. SYSTEM FOR SUB-AREA K

### 9.1 Drainage Plan

The area may be divided into three zones. The first is the hilly area located in the south of the Hong Xeng. This area is already urbanized and has rather steep slope. The storm water in the area is drained to the Hong Xeng. Since the area is fairly sloped, no water stagnates in the area and inundation has not occurred. No significant increase in the flood discharge is foreseeable because the area is already urbanized. Along this line no special drainage improvement is considered for the area.

The second is the other hilly area located in the northern part of the Sub-area. The area has a certain slope and no water stagnation occurs. The storm water in the area is drained into the irrigation drainage canal which runs through the sub-area from north-east to south-west and joins the Hong Xeng at near Phon Kheng village. The flood from the hilly area has been accommodated in the irrigation canal without causing any difficulty. Since the area is already urbanized, no significant increase in the flood discharge from the area is foreseeable. Consequently no special drainage improvement is considered for the area.

The other is the area enclosed by the Hong Xeng, the irrigation drainage canal and the national highway route No. 13. The topography of this area is low and flat. Paddy cultivation is the main land use so far. The area is susceptible to inundation. The area of 30 ha is planned to be urbanized along the national highway route No. 13 by the year 2020. The improvement of lateral canals in this 30 ha is necessary.

The southern part of 30 ha may be drained by the canal along route 13 and finally discharged to the Hong Xeng at the just upstream from the bridge on route No. 13. Meanwhile the water from the northern part of the area is conveyed to the culvert which cross the route No. 13. The culverts are connected to the canals which joint to the Houei Makhiao.

The canals and culverts to be improved are 6 and 3 respectively. The locations of canals and culverts are shown in Fig. 9.1.

### 9.2 The Principal Features of the System for Sub-area K

The improvements of 6 canals and 3 culverts are proposed for the drainage system in the Sub-area K. the main features are summarized as follows;

### Lateral No. 1

Design discharge	0.51 m <sup>3</sup> /s
Length	310 m
Width	0.6 m
Slope	1 to 370

### Lateral No. 2

Design discharge	$0.68  \mathrm{m}^3$
Length	390 m
Width	0.8 m
Slope	1 to 670

### Lateral No. 3

Design discharge	$1.05 \text{ m}^3/\text{s}$
Length	270 m
Width	1.0 m
Slope	1 to 670

### Lateral No. 4

Design discharge	$0.39 \text{ m}^3/\text{s}$
Length	230 m
Width	0.7 m
Slope	1 to 670

### Lateral No. 5

Design	discharge	$2.26 \text{ m}^{3}/\text{s}$
Length		230 m
Width		1.3 m
Slope	* .	1 to 670

### Lateral No. 6

Design discharge 0.26 m<sup>3</sup>/s

Length 310 m

Width 0.6 m

Slope 1 to 670

### Culvert No. 1

Design discharge 1.42 m<sup>3</sup>/s
Length 20 m
Width 1.25 m
Height 1.25 m

### Culvert No. 2

Design discharge  $2.26 \text{ m}^3/\text{s}$ Length 20 mWidth 1.5 mHeight 1.5 m

### Culvert No. 3

Design discharge  $0.26 \text{ m}^3/\text{s}$ Length 20 mWidth 1.0 mHeight 1.0 m

### 9.3 Construction Plan and Cost Estimate

### 9.3.1 Construction Schedule

Main works for the drainage improvement in the Sub-area K is the improvement of the lateral canal for 1,800 m.

The construction schedule for the Sub-area K is 24 month as described below;

### (1) Project Schedule

The target date for completion of the Sub-area K is assumed to be the 24th month. Approximately, 2 years respectively would be required for the System for Sub-area K from the commencement of engineering detailed design to the completion of construction work. The necessary periods are summarized as follows;

a) Engineering design including preparation of tender documents, and prequalification

6 months

b) Tendering

6 months

c) Main construction works

24 months

### The First Year

- a) Signing of Exchange Notes
- b) Selection and contract of consultant
- c) Detailed design and preparation of tender documents
- d) Advertising
- e) Prequalification
- f) Tendering and evaluation of civil works

### The Second Year

- a) Care of water and dewatering
- b) Fascine hurdle with sand bags (coffering)
- c) Excavation and concrete work of lateral canal
- d) Excavation and concrete work of box culvert

### The Third Year

- a) Care of water and dewatering
- b) Fascine hurdle with sand bags (coffering)
- c) Excavation and concrete work of lateral canal and street inlet structure
- d) Finishing works

The construction schedule is presented in Fig. 9.2.

### 9.3.2 Construction Method for Lateral Canal

The construction of lateral canal improvement will be carried out divided into several stages of the construction section in order to secure the drainage system during construction.

Based on the run-off discharge to the drainage canal and economical point of view, it is planned that the lateral canal improvement works should be carried out by the stepwise construction taking account of the site conditions. The works will be executed by two to three crews in a parallel way.

Excavation will be carried out by a back hoe and dump trucks for hauling works.

A portable type of concrete mixer will be provided for the small quantity of concrete of the lateral canal improvement works.

There are crossing utilities in the Vientiane city Intercepter such as power lines, water supply pipes and telephone lines.

Those facilities are planned to be replaced following to drainage canal works.

Required works for renewal will be conducted by the nominated contractors of each agencies.

### 9.3.3 Cost Estimate

The main construction works for the improvement of the drainage system in the area are the improvement of the lateral canals. The works are the excavation of earth and concrete works for canal lining and culvert. The installation of the pipe culverts the other substantial works. The work volumes thereof are estimated as summarized below;

Reinforcement bar 105 ton
Manhole cover 180 nos.

The estimated unit prices as described in Part I is applied to the work volume estimated and the direct cost is estimated.

In addition to this, indirect costs are estimated. Indirect costs comprise the land acquisition cost, engineering service cost and government's administration cost including the operation, maintenance and repair costs. The land acquisition cost or the compensation costs were estimated on the basis of the area for the right-of-way and the unit price of land. The engineering service cost and the government's administration cost are estimated on manmonth basis to cover the costs of supervisions and management of the Project.

The financial costs thus estimated are summarized as follows;

	Item	Foreign (¥1,000)	Foreign (US\$1,000)	Total (Equivalent) (US\$1,000)
(1)	Direct Cost			
	Lateral canal-1	37,797	207	475
	Lateral canal-2	184,851	1,012	2,323
	(Direct cost total)	222,648	1,219	2,798
(2)	Indirect Cost			
	a) Land acquisition	· · · · · · · · · · · · · · · · · · ·	· · · · · · · · · · · · · · · · · · ·	-
	b) Government's administration	, <del>.</del>	65	65
	c) Engineering service	42,624	41	343
	d) O&M equipment	. : <u> </u>	224	224
	(Indirect cost total)	42,624	330	632
(3)	Physical contingency	22,265	122	280
4)	Grand total	287,537	1,671	3,710

(Current price as of October 1989)

### 9.4 Economic Evaluation

### 9.4.1 Conditions Adopted in the Evaluation

Several conditions are employed in this economic evaluation. the time basis for the estimations of benefit and cost are set at October 1989. The foreign exchange rate adopted are as follows;

Japanese Yen 100 = Kip 418 = US \$ 0.709

In other words, US\$1.0 is equivalent to Kip 590 or Yen 141.

The project life is assumed to be 50 year. The OMR cost after 2020 is assumed to be the same with that at present. The benefit after 2020 is assumed to increase in accordance with the growth of GRDP. The improvements of the lateral canals may increase the peak outflow. However the discharge from this 30 ha is assumed to be absorbed in the surrounding paddy fields. Consequently the adverse effect due to the proposed improvement is supposed to be insignificant.

### 9.4.2 Economic Benefit of the Drainage Improvement

The study on the inundation damage in the study area yielded the following proportions of damage by the magnitudes of storms. Where the estimated damage to be incurred by 10-year storm is assumed 100;

2-year	storm	21
5-year	storm	86
10-year	storm	106
20-year	storm	114
50-year	storm	133

Since the main drainage is to be improved with the design discharge by 10-year storm and lateral drainage by 2-year storm, the damage reduction thereby is not always 100%. The analysis of the field survey yielded the following rates of damage reduction;

2-year	storm	100%
5-year	storm	72%
10-year	storm	48%
20-year	storm	38%
50-year	storm	25%

The figure indicates that if a 5-year storm occurs, 72% of potential damage is reduced but 28% of damage may remain.

According to the results of the damage analysis, a small storm, smaller than 2-year storm which bring about inundation damage to the area occurs 4 times a year on an average. The average damage incurred thereby is estimated to be 5% of one by 10-year storm.

The possible benefit of the drainage improvement is obtained as the expectation of the total damage reduction. The estimated average annual benefits by area and by year are presented in Table 9.1 up to the year 2040. The benefit of the Hong Ke system is obtained by the benefit of the Sub-area K.

The project is assumed to yield benefit after the completion of the main works. The damage reductions in the areas lower than El. 168.0 m should be smaller than that in the areas above El. 168.0 m. The damage reduction thereof is assumed to be 20% of that in the area above El. 168.0 m.

### 9.4.3 Economic Cost of Drainage Improvement

The economic cost is estimated on the basis of the estimated financial cost. The methods adopted to the conversion are described below;

- (1) Foreign currency portion: The import tax of 5% is deducted.
- (2) Tradable goods: A conversion factor of 0.9 is applied.
- (3) Labour cost: A shadow wage rate of 0.37 and a conversion factor of 0.9 are applied.
- (4) Land acquisition cost for farm land: Production foregone is applied.
- (5) Building: A conversion factor of 0.9 is applied.

- (6) The direct cost for the improvement of lateral canals are estimated by applying the unit cost of US\$24,000/ha to the urbanized area. The indirect cost is assumed to be 30% of the obtained direct cost.
  - (7) The OMR cost is estimated to be 1% of the construction cost.

The costs for the main works are presented in Table 9.2. The costs for the improvement of lateral canal are summarized in Table 9.3.

### 9.4.4 Economic Internal Rate of Return (EIRR)

A cash flow for the drainage improvement in the Sub-area K system is prepared as shown in Table 9.4. The obtained EIRR is 3.5%.

## PART IV.

# IMPLEMENTATION PROGRAM AND RECOMMENDATIONS

# PART IV. IMPLEMENTATION PROGRAM AND RECOMMENDATIONS

### CHAPTER 10. IMPLEMENTATION PROGRAM

### 10.1 Priority of Whole Project

The economic internal rate of returns are estimated as follows;

Hong Ke system	: 7.3%
System for Sub-area L (Nam Pasak)	: 4.2%
System for Sub-area I (Hong Kai Keo)	: 3.5%
System for Sub-area K	: 3.5%

In view of other aspects such as environment, the highest priority of the Hong Ke system cannot be denied. The Nam Pasak system may follow the Hong Ke system. The economic priorities of Sub-area I and K are equivalent. The urbanization in the area along the national highway route No. 13 in the Sub-area K may precede to the urbanization of Sub-area I. In view of this, the improvement in Sub-area K is scheduled next to the System for Sub-area L. consequently the improvement of the Hong Kai Keo system come to the fourth adjacent to the improvement of Sub-area K.

As discussed in the Basic Plan in Part 2 of this report, the priority of Subareas J, O, M and N follow the four systems mentioned above. The improvements therein should be implemented in the fifth stage. The priority of Sub-areas A and B is the lowest. And the drainage systems therein may be improved in the last stage as sixth project.

### 10.2 Implementation Schedule

All the projects are assumed to be constructed under contract base. And the implementation comprises preconstruction works and construction works. Preconstruction work period comprises the engineering design of 6 months and tendering of 6 months. The actual construction is mainly carried out during the dry season. The period necessary for the construction depend on

the work volume. The constructions of the Hong Ke system, System for Sub-area L (Nam Pasak), Systems for Sub-areas J, O, M and L and Systems for Sub-areas A and B have rather large volume of earth works which are liable to be affected by rainfall and the periods for the constructions thereof are estimated to be 24 months. Meanwhile the constructions of the System for Sub-area I (Hong Kai Keo) and Sub-area K may be completed within 12 months.

The preconstruction works of the Hong Ke system may be commenced in the first year of the Master Plan period of 30 years. The actual constructions thereof are commenced in the second year and completed at the end of the third year. The detailed design for the System for Sub-area L may be carried out thereafter. The proposed implement program is scheduled as shown in Fig. 10.1. The whole project is completed by the end of 23 years.

### 10.3 Organization and Budgetary Allotment

The construction of the drainage system has been carried out by municipality of Vientiane. The works have been usually entrusted to a state owned construction company. However the projects might be constructed by contractor under contract base because the projects have considerable work The state companies may join to the volumes and are technically complicated. works forming joint venture with the contractors. As the implementing agency, the department should employ more staff to reinforce its administrative and technical abilities. An independent department may be established if it is necessary for the construction, operation, maintenance and The required staff exclusive for construction, operation, maintenance and repair tentatively estimated as shown in Table 10.1.

The constructions of the identified six projects are allotted in 23 years as mentioned in the previous subsection. The investment thereto are disbursed in the period. In addition to the investment for the constructions of the projects, the investment is necessary for the lateral improvement in accordance with the improvement schedule. The budgetary arrangement is necessary for the OMR cost as the annual expenditure. The investment costs including O&M equipment cost except cost for O&M material, stuff and labour is estimated and summarized in Table 10.2 in line with the proposed implementation schedule. The investment costs at the time basis of October 1989 are summed up as follows;

Project implementation US\$51,964 x 10<sup>3</sup> Improvement of lateral US\$23,488 x 10<sup>3</sup> Total investment US\$75,452 x 10<sup>3</sup>

The overall EIRR of the Basic Plan is estimated to be 6.0% as shown in Table 10.3.

### CHAPTER 11. RECOMMENDATIONS

- (1) The Hong Ke system attested to be economically viable and technically sound. With urbanization and intensification of the land use in the area, the inundation damage will increase remarkably. In view of this, implementation of the proposed Hong Ke system should be undertaken urgently.
- (2) In order to make improvement of the main drainage system effective, the improvement of lateral canals is one of the most important works to be carried out by the Government of Lao P.D.R. The Municipality should accelerate the progress of this improvement work.
- (3) Other related urban plans should be consistent with the proposed drainage improvement plans so that safety against inundation and enhancement of amenity contemplated in this Study can be secured.
- (4) In order to realize the drainage master plan smoothly and effectively, the reinforcement of the executive agency and budgetary arrangement will be indispensable. The channels of communication with concerned agencies should be enhanced to achieve better coordination with other related plans.
- (5) The water quality of the drainage water is poor due to the influx of domestic sewerage. The pollutant loads may increase with the growth in population and economic activities in the Study area. In order to secure the amenity for the local residents and to improve the sanitary condition, the water quality should be improved. In this connection, the introduction of sewerage systems and garbage collection and treatment system should be considered. Amongst these, garbage treatment is considered to be of the most urgent need.
- (6) The continuous maintenance and cleaning of the proposed drainage canals will contribute to the improvement of the water quality. The siltings of the suspended solid should be trapped and removed periodically. The dilution of polluted water by introducing fresh water

from the Mekong and/or groundwater will be effective during the dry season. The artificial agitation of water by means of pumping will increase DO and be effective in improving water quality. These measures should be adopted as soon as convenient. In this connection the periodic monitoring of water quality is recommended, as well as the continuous data collection on storm rainfall and water levels by the instruments installed by the Study team.

- (7) The drainage plan should be consistent with the development plan of the Houei Makhiao river basin, since the plan proposes the discharge of storm water to the Houei Makhiao. This river has large retarding spaces enough to accommodate the water without causing any significant adverse effect thereto. In this connection, data collection and recording should be commenced as soon as possible for hydrology, topography and socio-economy including water quality and environment.
- (8) At present, the management of rivers is not integrated and no regulation have been enacted on the water right with regard to quality and quantity. The situation may cause institutional difficulty in the drainage management. It is recommended that the Government establishes an integrated institution and regulations for the improvement and OMR of drainage systems.

Table 3.1 Development Concept by Stretch

Stretch	Zoning for Drainage	Zoning for Environment	Development concept
Hong Ke (1)	Improvement	Urban green	Improvement of safety and development of green areas corresponding to the urbanization
Khoua Khao (II)	Retarding	Urban scenery	Generation of water space andn development of green areas and amenity water front
Hong Thong (III)	Retarding	Urban scenery	Generation of water space and development of green areas and amenity water front
Nam Pasak (IV)	Improvement	Reconstruction	Regional reconstruction and improvement of sanitary condition.
Nam Pasak (V)	Improvement	Reconstruction Urban green	Regional reconstruction and development
Nam Pasak (VI)	Retention	Rural green	Development of rural green areas coincide with rural area.
Hong Xeng (VII)	Improvement	Rural green	Development of rural green and fishery spots.  Conservation of drainage and irrigation function
Wat Tai (VIII)	Retention	Rural green Urban green	Development of green areas coincide with rural area and development of scenery.
Souan Moan (IX)	Retention	Rural green	Development of green areas coincide with rural area.
Souan Moan (X)	Retention	Rural green	Development of green areas coincide with rural area.
Nong Chanh (XI)	Retarding	Urban scenery Water front recreation	Development of multipurpose retarding basin. Development recreation spot.
Nong Duang (XII)	Retarding	Urban green	Development of multipurpose retarding basin and of urban green area.
Nong Bong (XIII)	Retarding	Urban scenery	Creation of amenity water front.

<sup>\*1</sup> In 1991, the following cost is disbursed for construction of 3 km of the model lateral canal in Hong Ke area.

 $US$1,174 \times 10^3$ Financial cost  $US$1,025 \times 10^3$ Economic cost

After 1993, the construction cost of remaining area are disbursed as shown in above table.
