THE DISASTER PREVENTION AND RESTORATION PROJECT IN

SERRA DO MAR, CUBATÃO REGION, STATE OF SÃO PAULO

FINAL REPORT

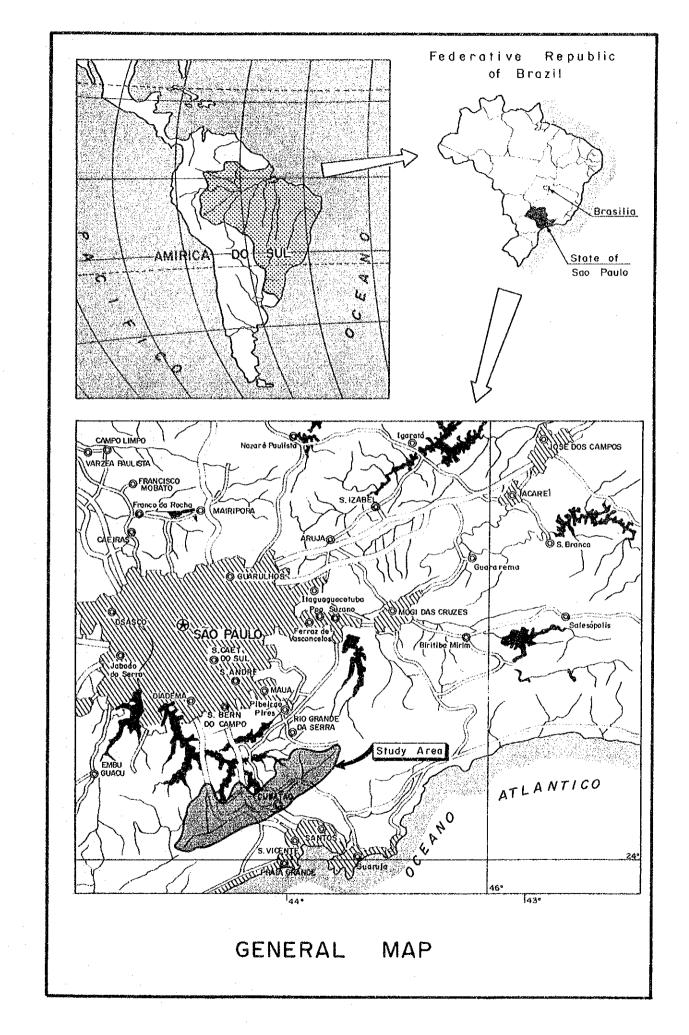

EXECUTIVE SUMMARY

JANUARY 1991

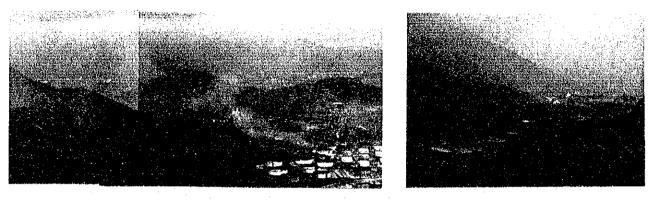

JAPAN INTERNATIONAL COOPERATION AGENCY

国際協力事業団 22065

A general view of CUBATAO industrial complex and CUBATAO City.

Air pollutant gases lanched from industrial establishment; Winds bring gases to the mountain side in daytime. Refinaria(left), Ultrafeltil and Copebras(right).

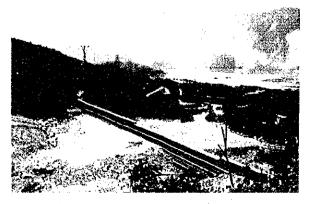

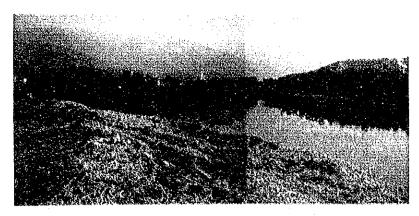

A large number of slope failures occured on the steep slopes upstream of the Moji River on Jan 22-25, 1985. Almost high trees standing on the slopes had already been dead by 1985's disaster(right).

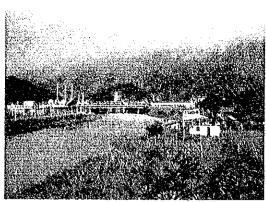

An aerial view of the riprap cross dam with sediment deposit mid-stream of the Moji River.

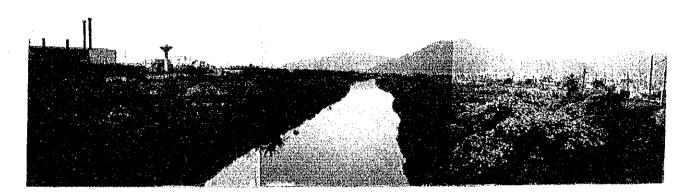

A series of three gabion dams constructed upstream of Ultrafertil.

Confluence of the Cubatão and the Pereque River; Flood dyke was constructed on right bank after the Industrial and residential areas are destructive disaster in 1971.

Lower reaches of the Cubatão River; developed along the both sides.

Lower reaches of the Moji River; where river channel improvement works are proposed in the priority project.

Monitoring on the control area after 3 months of seeding.

Young plant of Miconia sp, 50 cm tall, after 10 months of the aerial seeding.

1. BACKGROUND

The study area, situated in a coastal mountain and plain area 60 km south of São Paulo, is characterized by development of heavy chemical industry and its tropical forest. However, since the mid-1970s, a number of slope failures have occurred which cause sediment run-off disasters to the industrial establishments, infrastructures and residences. These are frequently on the steep slopes of Sera do Mar, in rainy seasons, and mainly due to the degradation of vegetation by air pollution.

The lower reaches of the Moji and Cubatao rivers also suffer flood disasters, especially in the downstream reaches of the Moji river.

With the aim of restoring the damaged slopes of Serra do Mar, the Special Commission has been steadily undertaking various disaster prevention plans consisting of structural and non-structural measures, including a vegetation restoration plan, with the support of the several agencies concerned.

To cope with these disasters, the Goverment of the Federative Republic of Brazil, in October 1988, requested technical assistance in a study on sediment run-off and flood disaster prevention in this region. In response to this request, the Government of Japan(JICA) sent to Brazil a study team between November 1989 and September 1990 to conduct the study.

2. OBJECTIVES

The objectives of the study are: 1) to formulate a master plan to the year 2000 and to select a priority project, 2) to conduct a feasibility study on the priority project by the mid-1990s, and 3) technical transfer to the Brazilian counterpart personnel. 3. PRESENT CONDITIONS

3.1 Socio-Economy

(1) Population and labor force

Brazil's population in 1980 was 119.0 million with a population density of 14.0 persons/km². This population is expected to reach 150.4 million in 1990 with a population density of 17.6 persons/km². The country's labor force was estimated to have increased to 59.5 million by 1987 with an average annual growth rate of 4.682.

The population of the State of São Paulo in 1980 was 25.0 million, which a population density of 100.9 persons/km². This population was estimated at 31.1 million in 1987 with a population density of 125.4 persons/km².

The population in Cubatão municipality in 1980 was recorded as 79,162, with a population density of 345.6 persons/km². This population is estimated to be 105,547 in 1990, with a population density of 713.1 person/km². The labor force in Cubatão was 31,576 in 1980 and is estimated to be approximately 42,100 in 1990. The detailed population growth and labor face are shown in Table 1.

(2) Economic performance

Gross Domestic Product (GDP) in 1988 was Cr\$ 91,952 million (US\$ 279.5 billion) at current prices. GDP at current prices has increased astronomically in the last two decades due to inflation. In real terms, however, Cr\$ 12,402 million in 1980, Cr\$ 13,111 million in 1985 and Cr\$ 14,613 million in 1988 at 1980 constant prices, with an average annual growth of 2.07% for the period of 1980-88. Per capita GDP in 1988 was Cr\$ 636.7 (US\$ 1,935) at current prices. In real terms, however, it was Cr\$ 0.101 at 1980 constant prices, compared with Cr\$ 0.102 in 1980, indicating no real increase in per capita GDP.

Gross Regional Domestic Product (GRDP) in the State of São Paulo was Cr\$ 64 thousand in 1970, Cr\$ 341 thousand in 1975 and Cr\$ 4,605 thousand in 1980 at current prices, respectively. Per capital GRDP in 1980 was Cr\$ 0.184, which was 1.76 times larger than that of GDP. This

- 2 -

ratio has gradually decreased from 1.96 in 1970, and 1.85 in 1975. The detailed data on GDP and GRDP are tabulated in Table 2.

The economic activities in the study area are dominated by the industrial sector, represented by the major industrial establishments in Cubatão municipality. This is one of the nation's largest industrial complexes and has been in operation since the 1950s. Its main products are petroleum, petro-chemical products, iron and steel, chemicals, and mixed fertilizers.

(3) Present land use

The total land in the study area amounting to 252 km^2 is currently used as follows: 1) 5.0 km² or 2.0% of the total land is built-up area, 2) 22.9 km² or 9.1% is industrial area, 3) 18.3 km² or 7.2% is grassland, and 4) 205.8 km² or 81.7% is forest and bush. The present land use (1990) is shown in Fig.1.

(4) Infrastructure

In the study area, there are four(4) arterial highway maintained by the state government, SP-150, Anchieta, SP-160 and Imigrantes.

All the residences in Cubatão municipality were supplied with municipal water in 1988, whereas the sewerage system covers only 1% of all the residences. Approximately 75% of the whole residences were covered by the electricity supply in 1988.

3.2 Sediment Run-off and Flood Damage

(1) Sediment run-off damage

According to records on the past disasters, a large number of small scale landslides on the steep slopes of Serra do Mar have occurred every 5 to 10 years in rainly seasons. Six(6) major sediment run-off have occurred since 1960: in 1962, 1971, 1976, 1980, 1985 and 1988 as shown in Fig.2. Of the above, sediment run-off disaster in 1985 was the largest in scale. The damage included destruction of machines, equipment and installations damage to inventory stocks, and even temporary suspension of production lines. The total direct damages and losses due

- 3 -

to this disaster was reported to amount to approximately Cr\$ 17.2 million.

(2) Flood damage

Past large scale floods occurred in 1968, Feb. 1971, Jan. 1973, Jan. 1976, Nov. 1979, Jan. 1983, Jan. 1985 and Dec. 1988. Of these, the 1971 flood was most serious.

In Feb. 1971, the urban area of Cubatão was inundated by river water which overflowed from the Cubatão and Pereque rivers as shown in Fig. 3. In addition, sea water which intruded in the low lying areas near the marsh enhanced the effect of inundation coupled with local rain water, and aggravated the flood. The flood damage was estimated to have been Cr\$ 18.5 million at 1973 prices, comprising Cr\$ 13.2 million in Cubatão river basin and Cr\$ 5.3 million in Moji river basin, respectively.

3.3 Existing Disaster Prevention Structures

Major structures for sediment run-off control are riprap cross dams and gabion dams in the valley areas to protect specific industrial establishments. While, those for flood control are flood dikes to protect the urban area form flooding as shown in Fig.4.

3.4 Non-structural Measures

Major non-structural measures in the study area have been relocation of residents in danger areas a civil defense plan, air pollution control, experimental planting and so on. The objectives of the civil defense plan are 1) to protect residents from disasters (evacuation plan) and 2) to eliminate situations were accidents in the industrial establishments induced by disasters could cause dangerous harm to the residents (management plan).

3.5 Topography and Geology

The study area is topographically divided into three(3); a plateau area, a mountain slope area and a plain area. The study area is

- 4 -

mainly dominated by migmatites, schists and sporadically intrusive granite of Pre-Cambrian age as illustrated in Figs.5 and 6. The migmatites including gneiss and quartzite are massive, sound and well jointed. They feature steep slopes with gradients of more than 30° , continuous outcrops and large scale waterfalls. The schists are characterized by gentle slopes because of their schistosity and foliation. Generally, the rocks strike NE-SW and dip at 60-80 NW and are faulted in the same direction as the strike. From the confluence of the Cubatao and Moji rivers to the estuary, fine sand and clayey soils with organic matter of Holocene age are found at swamps in the plain area.

3.6 Present River Conditions

(1) River basins and systems

Mainstreams in the study area are the Cubatão river (A= 183 km^2) and Moji river (A= 64 km^2). Main tributaries are the Perequêand Pilões of the Cubatão river, and Piaçaguera, Indio and Onça of the Moji river. The Cubatão river with a total length of 39 km originates near the Billings reservoir on the north west plateau at an altitude of 700 m. While, the Moji river having a total length of 18 km originates on the north east mountain slope at an altitude of 800 m. The longitudinal profiles of the rivers are shown in Fig.7.

(2) Carrying capacities of channels

Carrying capacities of the existing channels were estimated by the non-uniform flow method. The average carrying capacity in the lower and middle reaches of the Cubatão is from 800 to 1000 m³/s (w=1/5 or more) except upstream of the Anchieta bridge, which is less than 500 m³/s. Average capacity in the Perequê is less than 200 m³/s (w=1/2) downstream of RFFSA bridge and 500 m³/s (w=1/25) in the upstream reaches. While, that of the Moji was estimated to be below 300 m³/s (less than w=1/2).

3.7 Meteorology and Hydrology

(1) Climatic conditions

An average annual rainfall is around 3,400mm on the mountain

- 5 -

slopes (EL.500m) and 2,700mm in the plan area. About 75% of the annual rainfall is concentrated in the summer. The mean temperature in Cubatão city is around 25° C in the summer and 20° C in the winter, and the mean relative humidity is around 74%. Present rainfall stations and their record availability are shown in Fig.8.

(2) Rainfall analysis

The average monthly rainfall fluctuates from 400 to 460 mm on the mountain slopes and from 320 to 340 mm on the plan area. Rainfall is mostly concentrated at night. The average duration of rainfall is around 50 hours ranging from 34 to 63 hours and about 90% of the total rainfall depth has been concentrated in 2 days in the eight(8) main floods of recent times.

The probable basin mean rainfall and point rainfall were estimated by the Gumbel method as follows:

Return	Basin Mean Ra:	infall (2-day)	Point Rainfall (2-day)		
Period (yr)	Cubatão Basin	Moji Basin	E3-153R (Cubatao)	E3-038R (Moji)	
2	205.7	182.3	233.1	191.5	
5	281.2	249.9	311.4	262.7	
10	331.2	294.6	363.3	309.9	
25	394.2	351.1	428.9	369.4	
50	441.3	393.0	477.5	413.6	
100	487.8	434.7	525.7	457.5	

Basin Mean Rainfall and Point Rainfall

(3) Run-off and discharge analysis

Probable flood run-off was estimated by using the storage function method and design hyetographs of the Feb. 1971 type in the Cubatao river basin and the Feb. 1985 type in the Moji river basin. The basin was divided into subbasins as shown in Fig.9 and estimated peak

- 6 -

discharges at main points are presented in Table 3. (4) Flooding analysis

Flooding analysis was conducted by constructing a simple hydraulic model in order to estimate inundation depths in the land areas. According to this analysis, it is observed that the inundation occurs with a five (5) year return period or more in the Cubatão river and a flood which possibly occurs every year in the Moji river.

3.8 Sedimentation

Channel sediment transport capacities were estimated for the Cubatão, Perequê and Moji rivers by three(3) kinds of sediment formulae. Of these formulae, the estimated capacities by Brown formula is most applicable to this study. It can be seen that there is wide variety in sediment capacity and therefore some reaches are relatively subject to sudden removal of accumulated sediment.

3.9 Sediment Run-off

Sediment run-off is the combined effect of slope failure and discharge of unstable torrent bed deposit. Slope failures in this study are small scale landslides on the steep mountain slopes. Distribution maps of total slope failures and individual past major failures are illustrated in Fig.10 and 11, and are summarized in Table 4.

The average area, depth to slip surface and volume of typical slope failures are considered to be 2,420 m^2 , 0.7 m and 1,700 m^3 , respectively.

Slope gradient, slope configuration and vegetation conditions can be identified as the main cause, and intensive rainfall as the trigger of slope failures. It is found that the slopes with gradients of less than 20° are free from slope failures, but those of greater than or equal to 30° are susceptible to the slope failures.

Vegetation degradation by air pollution has been recognized as one of the main causes of slope failures since the mid-1970s. In particular the vegetation of around 80 percent of the area had been degraded by pollution by 1977 and more than 95 percent by 1985.

- 7'-

With regard to the trigger of slope failures, the Special Commission has clarified the relationship between slope failures and rainfall such as rainfall intensity and accumulated rainfall. As a result of the analysis, 6-hour rainfall was considered to be the best index to estimate total area of slope failures.

Group Eq		Equation	Correlation Coefficient
A		Y = 0.46(X-63.3)	0.940
В		Y = 0.30(X-80.6)	0.944
C		Y = 0.21(X-80.3)	0.971
D	· . · .	-	a de la construction de la const
Е	:	-	and a second

Relationship between Slope Failures and Rainfall

Note: Y means total area (10^3 m^2) of slope failures per km² X means 6-hour rainfall (mm)

From the viewpoint of the soil mechanism, the reduction of apparent cohesion at the slip surface by the vertical infiltration and the saturated zone enlargement with time are considered to be main cause of the slope failures.

3.10 Vegetation and Soil

The forest, consisting of three(3) strata: upper, middle and lower, is widely covered with coppices (capoeira) including some subhigh trees of Tibouchina SP.

Soil types in the study area are Red Yellow Latosol, Red Yellow Podzolic Soil, Cambisol and Red Yellow Latosol Intergrade Red Yellow Podzolic Soil.

According to the vegetation maps prepared by CETESB shown in Fig.12, it can be seen that vegetation conditions have been remarkably degraded since the last half of the 1970s mainly due to air pollution.

CETESB and IBt have been conducting the forest restoration

- 8 -

activities according to the basic plan as shown in Fig.13.

3.11 Environment

(1) Air quality conditions

The study area has a remarkable agglomeration of air pollution sources emitted from the industrial complex in Cubatão. Facing serious pollution over the entire Cubatão municipality in early 1980's, air pollution control over the main pollution sources has been enforced since 1984 and has attained remarkable results.

The initial emission load of 557 tons per day in 1984 was reduced by 66% to around 187 tons per day in 1989. Annual change of industry products and SO_2/SO_3 concentration is illustrated in Fig.14.

(2) Gases hazardous to vegetation

Among the various kinds of hazardous gases observed in the study area, such gases as Sulfurous oxides (SOx), Fluoride (HF), Ozone, Ammonia and Nitrogen Oxides (NOx) are considered to be the main pollutants causing vegetation degradation. Air pollution intensity area is shown in Fig.15.

4. MASTER PLAN

The outline of the master plan formulated is shown in Fig.16 and its components are as follows:

4.1 Sediment Run-off Disaster Prevention Plan

(1) Basic considerations

The master plan for the sediment run-off disaster prevention was formulated on the assumption that the present vegetation conditions will not be improved in near future because of the difficulty in restoring completely degraded forest to original conditions by the year 2000. Accordingly,

- 9 -

- a protection area having 12 Sabo subbasins was chosen on grounds of probable slope failure, past major sediment run-off records and the properties at risk to be protected as shown in Fig.17.
- a design scale of 100 years was adopted for the following reasons; the importance of the area to be protected, the uncertainty of natural disaster phenomena and Japanese standards.

(2) Disaster prevention plan

Thirty-two(32) Sabo dams and eleven (11) channel improvement works with a total length of 5,740 m were proposed for the master plan as shown in Table 5 and Fig.18. The main dimensions of the proposed structures are shown below.

Onha	Structural Measures						
Sabo Subbasin No.	basin Sabo Dan			Channel Works	(m)		
_	_				<u>.</u>

Main Dimensions of Structures

- 10 -

4.2 Flood Disaster Prevention Plan

(1) Basic considerations

The master plan for flood disaster prevention was formulated on the basis of the following basic considerations.

- the urban area and industrial establishments in the fluvial plain shown in Fig.19 were determined to be the protected areas as follows:

Cubatao river (RFFSA bridge - Sabesp weir)

Perequê river (Road bridge at river mouth - Ultrafertil weir)

Piaçaguera river (Confluence with the Moji river - spillway of Copebras estate)

Indio river (Confluence with the Moji river - RFFSA bridge)

- the design scale of a 50-year return period was adopted for the mainstreams of the Cubatão and Moji rivers, and a 25-year return period for their tributaries by the reason of importance of protected area and the criteria applied in the State of São Paulo.

(2) Disaster prevention plan

Of the conceivable alternative schemes shown in Fig.20, schemes of C-2(2) in the Cubatão river basin and M-2 in the Moji river basin were selected as the optimum plan on the basis of least cost as shown in Fig.21.

Scheme C-2(2) consists of 2 tunnels of 600 m each and river channel improvement of 6.7 km, and scheme M-2 consists of 9.5 km of river channel improvement.

Work i	tems	Quantitie	96
Cubatão River	System		
Construct	ion of diversion tunnel	600 n	n
Channel i	mprovement	6.71	cm
<u>Moji River Sy</u>	stem		* : · · · ·
Channel i	mprovement	· · · ·	* :
	Moji	4.5 1	cm
	Piaçaguera	3.7 k	m
	Indio	1.3 k	A CONTRACT OF

4.3 Forest Restoration Plan

(1) Basic considerations

The present forest restoration plan of the State of São Paulo includes two stages, namely first stage; planting and aeroseeding or pioneer species, and second stage; replantation of the climax species in Capoelra area.

According to the monitoring survey conducted by CETESB on February 1990, first stage's works is judged to have finished with success results satisfactorily. Therefore, the second stage of the present forest restoration plan can be adopted as the master plan project with a target year of 2000.

Twenty(20) areas shown in Fig.22 were selected as the strategic replantation areas with a catchment area of 0.4 ha, respectively.

(2) Forest restoration plan

Replantation of one thousand trees in each wood area was proposed for the master plan. The work items and quantities are as shown next.

Item	Quantities		
Selection of climax species	-	••	
Seedling production	24,000	units	
Service roads restoration	35	km	
Topographic works	80,000	m ²	
Planting works	20,000	units	
Maintenance works	20,000	units	
Support works	<u>د</u>		

4.4 Non-structural Measures

Non-structural measures, in combination with structural measures, are effective and of vital importance in minimizing damage from natural disasters. From experiences Japan, the following points can be suggested.

- Preparation and publication
- Simplification of existing judgment and information transmitting systems
- Prompt and accurate management of existing observation stations

4.5 Implementation Program

(1) Implementation schedule

The implementation schedule of the master plan was prepared by taking into account the construction sequence and conditions. The total project period was assumed to be 10 years, in which the project period was divided into two(2) stages: the first five(5) years (1991-1995) and the second five(5) years (1996-2000). Implementation schedules for sediment run-off and flood disaster prevention works, and forest restoration plan are shown in Fig.23 and 24.

(2) Construction cost

The construction cost of the master plan on a financial basis was estimated for the sediment run-off and flood disaster prevention works as given below. The price level was set at the end of June 1990 and official exchange rates were fixed as US\$1.00 = Cr\$60. The detailed financial cost is tabulated in Table 6.

	· ·	(Unit: U	US\$ million	
Item	Financial	Direct	Indirect	
Sediment Run-off				
Prevention Plan	75.0	45.9	29.1	
Elend Dermanting Outot		05 5		
Flood Prevention - Cubatão Plan	43.2	25.5	17.7	
- Moji	22.7	13.9	8.8	
Forest Restoration Plan	2.0	1.7	0.3	
Total	142.9	87.0	55.9	
	······································	······	1. A. J.	

4.6 Project Justification

(1) Economic cost

The economic cost was estimated as follows:

	(outor oby mailing			
Sediment Run-off	Flood Disaste	r Prevention		
FIEVENCION	Cubatão	Moji		
· · · · · · · · · · · · · · · · · · ·

(Unit: US\$ million)

and the second second

- 14 -

(2) Economic benefit

The economic benefits were estimated as the reduction in damages or losses to damageable properties, which will be brought about by implementation of the designed disaster prevention works. Probable damages and annual damages were estiamted as follows:

		· .	· * · ·	(Unit:	US\$ million)
Sabo		Return Period			
Subbasin	5	25	50	100	Annual Damage
1	-	***	••	••	· · _ . · · .
2	0.4	6.0	7.0	7.7	0.8
3	0.3	4.6	8.1	8.1	0.6

- 15 -

(3) Economic evaluation

Economic evaluation was carried out to assess economic viability by comparing economic costs and benefits. The Economic Internal Rate of Return (EIRR) was used as the criterion as shown in the following table.

Item	Sediment Run-off	Flood Prevention Plan			
	Prevention Plan	Cubatão	Moji		
EIRR (Z)	11.2	5.4	8.3		

(4) Project justification

The master plan for the sediment run-off prevention works could be justified solely by EIRR of 11.2% quoted above. When the unmeasurable social impacts and intangible damages which would be induced from sediment run-off disasters are taken into account, this master plan was judged to be highly viable for implementation.

When regard to the master plan for the flood protection works, major industrial establishments are at high risk of recurrent inundation from the Moji river and its tributaries. In considering the future land use plan envisaged for the Moji river basin, the probable flood damages in future is likely to increase significantly as compared the present projection. If this is combined and with the economic evaluation the flood protection works for the Moji river basin is also highly viable.

The master plan for the forest restoration would be justified from effective erosion control aiming at preventing sediment run-off and flood disaster in the middle and long term.

5. SELECTION OF PRIORITY PROJECT

The priority project targeted on the mid-1990s was selected from the master plan as follows. The outline of the priority project is shown in Fig.25.

- 16 -

5.1 Sediment Run-off Disaster Prevention

Priority project was determined as shown below in accordance with the two selection priorities; the probability of serious disaster and EIRR. As a result, nine(9) Sabo dams, and six(6) channel works in seven(7) subbasins were selected as shown below. These structural measures were designed for the probable sediment run-off discharge of about a 25-year return period.

Subbasin												
Item	1	2	3	4	5	6	7	8	9	10	11	12
1st criteria		· +·	+				+	+		÷		
2nd criteria EIRR (%)	(-)	12.7	14.7	2.4	1.8	2.1	17.0	9.1	3.9	11.8	11.9	12.9
Priority Proj	ect	*	*				*	*		*.	*	*

Note: + means first priority subbasins having possibility of flowing out toxic gases and liquid in sediment run-off disaster * means selected priority project

5.2 Flood Disaster Prevention

About 4.5 km of channel improvement and flood dike construction on the Moji river, including the lower reaches of some tributaries were selected for the priority project because of their higher economic viability and the circumstances of recurrent inundation. These structural measures will be designed for a 10-year return period.

5.3 Forest Restoration Plan

Forest restoration works to be done by 1995 were selected as the priority project in accordance with the implementation program of the master plan.

- 17 -

The quantities of the forest restoration works in the priority project is summarized below:

Item	1. J. J. J.	Quantities		
Selection of climax species				
Seedling production		24,000 units		
Service roads restoration		35 km		
Topographic works		80,000 m ²		
Planting works		20,000 units		
Maintenance works		20,000 units		
Support works		an a		

The project cost for the priority project was estimated on the basis of the restoration plan in the master plan as shown below:

••••	ан сайтанан алар алар алар алар алар алар алар	(Uni	t : US\$ 1,000)
	Item		Project Cost
(1)	Direct Cost		
	. Service road	a garanta a	175
	. Topographic works		70
	. Seeding production		96
	. Planting works		80
	. Maintenance works		20
ъ.,	. Management works	· .	600
•	. Monitoring by aerophotos		60
	Sub-total		1,101
(2)	Contingency (20%)		224
	Total		1,325

6. FEASIBILITY STUDY ON PRIORITY PROJECT

6.1 Preliminary Design and Work Quantities

(1) Sediment run-off disaster prevention works

The preliminary design for the sediment run-off disaster prevention works was carried out based on the design criteria in Japan as shown in Fig.26 and 27. The work quantities of the sabo dams, channel works and groundsills are shown in Table 7 and they are summarized below.

	. 1	Dam	Channel Works	Groundsill		
Dam No.	H (m)	V (m ³)	L (m)	Nos	V (m ³)	
2-1	13	22,000	530	4	1,200	
3-1	14	9,800	490	1	200	
7-1	12	3,600	250	5	1,000	
7-3	14	3,800	-	. .		
7-4	12	2,000	_	-		
8-1	11	3,700	440	4	400	
10-1	9	1,100	-	-		
11-1	14	7,300	410	11	1,100	
12-1	13	4,900	750	9.	900	
Total		58,200	2,870	34	4,800	

Note: H; Dam height V; Volume of structure L; Total length

(2) Flood disaster prevention works

The preliminary design for the flood disaster prevention works was conducted in accordance with the criteria in Japan as shown in Fig.28 and 29. The work quantities of the river improvement works are as shown in Table 8 and they are summarized below.

Type of Structure	Quantity
	265,000 m ³
	334,000 m ³
	141,000 m ³
Wet masonry	9,800 m ²
	1.5m x 1.5m (6 sites)
the second second	2.0m x 2.5m (1 site)
Concrete	
Concrete	
	40.8 m
)	130.5 m
	Wet masonry Concrete

- 19 -

6.2 Construction Plan

The contract system considering the participation of foreign contractors associated with Brazilian contractors are proposed to execute the project works.

The projects will be proposed to be executed with four (4) packages taking into account the project scale, amount of construction costs and secure implementation.

6.3 Cost Estimate

The construction cost for the priority project was estimated based on the preliminary design and construction plan. The basic assumptions and conditions adopted for the cost estimate are basically the same as that of master plan stage. The detailed financial cost is tabulated in Table 9.

The construction costs for the priority projects in the financial basis were estimated as follows:

		· · ·	ъ.	(Unit: U	IS\$ milli	on)	
Item		ent Run ntion W		Flood Disaster Preventic Works Moji River			
· · ·	F/C	L/C	TOTAL	F/C	L/C	TOTAL	
I Preparatory Work (5-15% of II)	1.0	1.2	2.2	0.2	0.1	0.3	
II Construction Cost	7.0	7.8	14.8	4.0	3.1	7.1	
III Compensation Cost		0.1	0.1		0.2	0.2	
IV Administration Cost (5% of I + II)		0.9	0.9		0.4	0.4	
V Engineering Service (10% of I + II)	1.4	0.3	1.7	0.6	0.1	0.7	
VI Physical Contingency (15% of I+II+III+IV+V)	1.4	1.5	2.9	0.7	0.6	1.3	
VII Price Contingency (F/C 3%, L/C 3%)	1.5	1.6	3.1	0.8	0.6	1.4	
Total	12.3	13.4	25.7	6.3	5.1	11.4	

- 20. -

(Unit : million US\$)

		Construction Cost					
	Works	Direct	Indirect	Total			
(1)	Sediment run-off disaster prevention works	17.0	8.7	25.7			
	Basin 2	6.0	3.0	9.0			
	Basin 3	2.7	1.3	4.0			
:	Basin 7	2.7	1.4	4.1			
	Basin 8	1.1	0.8	1.9			
	Basin 10	0.3	0.1	0.4			
	Basin 11	2.2	1.1	3.3			
	Basin 12	2.0	1.0	3.0			
(2)	Flood disaster prevention works	7.4	4.0	11.4			
(3)	Forest restoration works	1.1	0.2	1.3			
	Total	25.5	12.9	38.4			

6.4 Project Economic Evaluation

(1) Economic cost

The constitution and concept of the economic cost for the priority project was assumed to be the same as applied in the master plan. The economic cost for the priority project was estimated as follows:

an a	Economic Cost						
	Direct	Indirect	Total				
(1) Sediment run-off disaster	15.1	4.9	20.0				
prevention works	-						
Basin 2	5.4	1.7	7.1				
Basin 3	2.3	0.8	3.1				
Basin 7	2.4	0.8	3.2				
Basin 8	1.1	0.3	1.4				
Basin 10	0.2	0.1	0.3				
Basin 11	1.9	0.6	2.5				
Basin 12	1.8	0.6	2.4				
(2) Flood disaster	6.8	2.2	9.0				
prevention works		 March 1997 March 1997					
Total	21.9	7.1	29.0				

(2) Economic benefit

The economic benefits were estimated as the reduction in damages or losses to damageable properties, which will be brought about by implementation of the designed disaster prevention works. Probable damages and annual damages were estiamted as follows:

Probable Sediment Run-off Damage and Annual Damage

...

		(Unit:					
	Return	······································	······································				
5	25	50	100	- Annual Damage			
1.0	<i></i>		_ •_	· ·			
	6.0	7.0	7.7	0.7			
0.3	4.6	6.2	8.1	0.4			
1.9	3.6	4.6	6.3	0.6			
0.7	0.8	1.1	1.4	0.2			
0.1	0.6	1.4	1.9	0.1			
1.4	2.2	2.7	3.1	0.4			
1.0	3.0	8.6	11.4	0.4			
	1.2 0.3 1.9 0.7 0.1 1.4	5 25 1.2 6.0 0.3 4.6 1.9 3.6 0.7 0.8 0.1 0.6 1.4 2.2	1.2 6.0 7.0 0.3 4.6 6.2 1.9 3.6 4.6 0.7 0.8 1.1 0.1 0.6 1.4 1.4 2.2 2.7	5 25 50 100 1.2 6.0 7.0 7.7 0.3 4.6 6.2 8.1 1.9 3.6 4.6 6.3 0.7 0.8 1.1 1.4 0.1 0.6 1.4 1.9 1.4 2.2 2.7 3.1

(3) Economic evaluation

e gala de la companya de la company

. .

An economic evaluation was carried out to ascertain the economic viability of the proposed projects by comparing the economic costs and benefits. The Economic Internal Rate of Return (EIRR) was applied as a criterion for economic evaluation.

	na synthesis i an an an an an a' an a'	and the second	÷

	1	21.2	
	12	22.3	
	Total	18.2	
	<u>River Improvement Works</u>	11.1	
		1	

6.5 Environmental Impact Assessment

As a result of environmental impact assessment based on the guide-line of the State of São Paulo, the environmental effects of the priority projects will be generally limited to the construction stage. However, the magnitude are expected to be small, because the impacts are tentative and effective countermeasures will be taken during construction of the projects.

6.6 Project Justification

Overall economic evaluation of the Sabo works, consisting of 7 Sabo sub-basins, shown an EIRR of 18.2%. Of the above, sub-basin No.7, 10, 11 and 12 were analyzed to exhibit quite high economic return of more than 20%. On the other hand, the Moji river improvement works shown an EIRR of 11.1%.

For the above-mentioned reasons, both the sediment run-off and the flood prevention works could be justified. Moreover, taking into account unmeasurable social impacts and intangible damage, these projects were judged to be highly viable for implementation.

7. RECOMMENDATION

1. The proposed priority project for the sediment run-off and flood disaster prevention works is strongly recommended to be implemented at the earliest possible time because of eminent social request from high potential of disaster, as shown that the project is technically feasible and economically viable with high economic return.

2. It is well known that the forest restoration plan is very important to protect industrial establishments and inhabitants from sediment runoff and flood disasters. Therefore, basic study on the relationship between vegetation changes and air pollution, and monitoring on the aeroplantation should be carried out in continuous and effective methods as applied presently.

In considering uncertainty and difficulty in predicting accurate time and location of occurrence for the sediment run-off disasters, the present civil defense plan and forest restoration program are also strongly requested to be continued as effective countermeasures which are complementary to the proposed priority project in order to restore forest in Serra do Mar.

3. Prior to the detailed design and during the construction, it is also recommended that geotechnical investigations for bearing capacity of foundation, cutting slope stability and bank materials should be carried

- 24 -

out because of complex geological conditions in the project area of the priority project.

4. Other projects in the Master plan especially diversion tunnel works including open channel through the marsh area, which were not selected as the priority project, could seem to cause relatively serious impact on mangrove and its neighboring environment. From the above, detailed environmental impact assessment should be undertaken before the project is implemented.
