Microscopic Observation of Rocks in Thin Section (Sedimentary Rocks) (1)

Sample Number	Rock Name (Geologic Unit)	Macroscopic Features / Microscopic Features	Identified Minerals and Material: Detrital Material	Identified Minerals and Material: Matrix
A007	ALTERED SANDSTONE (Mzm)	• White • Fine-grained • Massive compact ——— • Well-sorted	(90～95%) • Quartz ≒ 85%, < 0.2mm angular ～subangular monocrystalline grain • Alkali feldspar ≒ 10% partly or totally altered to sericite • Plagioclase rare • Rutile • Zircon	• Interstitial sericite • Clay minerals
A008	ALTERED SANDSTONE (Mzm)	• Light brownish gray • Medium-grained • Silicified • Small cavities-bearing • Limonite stained ——— • Poorly-sorted	(≒ 90%) • Quartz > 80%, < 1mm angular to subangular sericite along cracks and grain boundary • Zircon • Opaque (limonite)	• Interstitial sericite • Opaque (limonite) • Quartz
A009	ALTERED SANDSTONE (Mzm)	• Light brownish gray with white quartz veinlets • Medium-grained • Quartz veinlets < 1mm wide, small drooze-bearing • Compact ——— • Poorly-sorted • Partly sheared	(85～90%) • Quartz > 85%, < 2mm angular to subangular monocrystalline grains dusty appearance sericite along cracks and grain boundary • Zircon rare • Monazite (?) rare	• Quartz • Sericite • Opaque • Clay minerals
A031	LIMESTONE (K)	• Light brownish gray • Including oncoids (ϕ=1-10mm) and shell crust ——— • Spherical to ellipsoidal grains, consisting of micrite are oncoids	• Oncoid ≒ 5% < 5mm • Bioclast < 5% • Detrital quartz ≒ 20% < 0.1mm • Detrital plagioclase rare • Muscovite rare • Zircon rare	• Micritic carbonate

Microscopic Observation of Rocks in Thin Section (Sedimentary Rocks) (2)

Sample Number	Rock Name (Geologic Unit)	Macroscopic Features / Microscopic Features	Identified Minerals and Material: Detrital Material	Identified Minerals and Material: Matrix
(CONT.)		• Bioclasts (Brachiopod shell?)		
A041	SILTSTONE (MyCl)	• Brownish gray • Thin clear lamination • Quartz veinlets (w=0.5～5mm) • Host rock of Mkangombe North metalliferous vein --- • Poorly sorted • Parallel alignment of opaque-rich layer • Thin quartz vein (0.1～2mm thick) ≒ 10%	(20～30%) • Quartz ≒ 20%, 0.1mm angular • Plagioclase < 5%, < 0.1mm • Alkali feldspar < 5%, 0.1mm • Muscovite rare • Biotite rare • Opaque rare • Carbonate rare	• Sericite • Clay minerals • Opaque • Carbonate • Limonite
B006'	CARBONATED WOOD (Mzm)	• Dark gray • Compact • Including white carbonate film (W < 1mm) and pyritic concretion (ϕ = 0.5～2mm) --- • Granular dolomite	• No detrital material	• Dolomite > 90%, < 0.1mm irregular shape dusty appearance • Cavity filling calcite < 10%, < 0.2mm clear crystal • Unidentified brown material < 5% parallel alignment • Opaque • Limonite
B012	LIMESTONE (K)	• Light brownish gray • Massive compact • Spheroidal calcite, ϕ=1～8mm --- • Heterogenious rock consisting of ① Bioclasts ② Oncoids ③ Lithoclastic fragments	• Quartz ≒ 5% angular • Plagioclase rare • Oncoids ≒ 50%, < 7mm • Bioclasts totally replaced by sparitic calcite echinoderms ≒ 5%, ϕ=1mm • Lithoclastic	• Micritic carbonate • Partly sparitic calcite

Microscopic Observation of Rocks in Thin Section (Sedimentary Rocks) (3)

Sample Number	Rock Name (Geologic Unit)	Macroscopic Features / Microscopic Features	Identified Minerals and Material	
			Detrital Material	Matrix
(CONT.)			fragment ≒ 10% micritic calcite with detrital quartz	
B014	SANDY LIMESTONE (K)	• Light brown • Black dendritic mineral • Massive compact ——— • Dusty carbonate (sparite) predominant • No oncoid, ooids or bioclast • Clear clacite vein associated with opaque (limonite)	• Quartz ≒ 20%, < 0.2mm angular	• Dusty Carbonate ≒ 70%, < 0.2mm parts of grain boundary are coated by opaque (limonite)
B032	GRAYWACKE (MyCm)	• Light brown • Massive compact • Grit, ϕ < 2mm ——— • Poorly sorted	(70~80%) • Quartz ≒ 30% angular-sub-angular • Plagioclase ≒ 20% angular-subangular • Alkalifeldspar ≒ 30% angular-sub-angular microcline, perthite partly altered to sericite • Calcite rare, well rounded • Limonite • Rock fragments rare granitic rock	• Carbonate • Opaque • Plagioclase • Quartz • Chlorite
B037	SILTSTONE (MyCM)	• Olive green • Massive compact ——— • Well sorted • Rough parallel alignment of muscovite and biotite flakes • Imbrication of quartz and feld-	(≒ 90%) • Quartz ≒ 70%, < 0.05mm rounded~sub-rounded • Carbonate ≒ 10% rounded~subrounded • Muscovite flake ≒ 5%, < 0.05mm	

Microscopic Observation of Rocks in Thin Section (Sedimentary Rocks) (4)

Sample Number	Rock Name (Geologic Unit)	Macroscopic Features / Microscopic Features	Identified Minerals and Material	
			Detrital Material	Matrix
(CONT.)		spar grains	• Biotite flake ≒ 5%, < 0.05mm, chloritized • Plagioclase ≒ 5% • Alkalifeldspar ≒ 5% • Zircon rare • Opaque rare • Monazite rare • Limonite	
B051	SANDSTONE (MKm)	• Light brown • Very fine-grained • Massive compact • No lamination and grading ——— • Well sorted • Weak parallel alignment of muscovite and biotite flakes	(90～95%) • Quartz ≒ 50%, < 0.1mm angular ～subangular • Alkalifeldspar ≒ 30%, < 0.1mm angular～sub-angular, partly altered to sericite • Plagioclase ≒ 10%, < 0.1mm angular～sub-angular • Muscovite • Biotite • Opaque	
C001	SANDY ÖOLITIC LIMESTONE	• Light brownish gray • Massive compact • Fine grains of dark gray detrital quartz • No lamination and stratification ——— • Spherical to ellipsoidal grains with con-centric laminae are öoids. Some öoids make compound grains • Peloids present • Bioclast and oncoids (≒ 3mm) present	• Quartz < 10%, 0.4mm some quartz are nuclei of öoids • Zircon rare • Lithoclasts rare	• Sparitic calcite

Microscopic Observation of Rocks in Thin Section (Sedimentary Rocks) (5)

Sample Number	Rock Name (Geologic Unit)	Macroscopic Features / Microscopic Features	Identified Minerals and Material: Detrital Material	Identified Minerals and Material: Matrix
C005	SANDSTONE (Mzm)	• Light brown (weathering color) • Massive compact • No lamination and grading ——— • Well sorted	(80～90%) • Quartz ≒ 70%, < 1mm, sub-angular～sub-rounded • Plagioclase ≒ 5%, < 1mm • Alkalifeldspar ≒ 10%, < 1mm partly altered to sericite	• Sericite • Chlorite • Clay minerals • Opalque, partly to totally altered to limonite
E002	SANDSTONE (Mzm)	• Light brown with black spots • Very fine-grained • Massive compact • No lamination and grading ——— • Well sorted	(90～95%) • Quartz ≒ 70%, < 0.3mm sub-angular～sub-rounded • Alkalifeldspar ≒ 20%, < 0.3mm • Plagioclase ≒ 10% • Garnet < 5% • Opaque < 5% • Apatite • Biotite • Zircon • Monazite ?	• Opaque ≒ 5% • Muscovite
G013	SILICIFIED SANDSTONE (MyCu)	• Light brown • Very fine-grained • White quartz veinlets with small drooze, w < 1mm • Weakly brecciated ——— • Well sorted • Parallel alignment of muscovite and biotite flakes • Angular sandstone fragments (breccia) ϕ=1mm～2cm	Sandstone fragments (80%) • Quartz ≒ 60%, < 0.1mm angular ～subangular • Plagioclase ≒ 20%, < 0.1mm • Alkalifeldspar ≒ 20%, < 0.1mm • Muscovite • Biotite • Opaque	• Quartz < 0.3mm angular, sutured crystal boundary
G022	SANDSTONE (MyCu)	• Light olive gray • Very fine-grained • Massive compact • Obscure lamination ——— • Well sorted	(60～70%) • Quartz ≒ 80%, < 0.1mm angular • Plagioclase ≒ 10% • Alkalifeldspar	• Chlorite • Clayminerals • Sericite • Carbonate

Results of microscopic mineral identification
of ore specimens on polished sections

1) Sample, weathered carbonatite, Mrima-Jombo Area, number A034

Chiefly composed of white diaphanous minerals with sparse disseminations of gains or aggregates of strongly magnetic black and dark brown minerals by unaided eye.

Under the microscope, black minerals are of pyrrhotite-associated chalcopyrite, dark brown minerals are of iron hydroxide minerals. Primary metallic minerals wholly consist of pyrrhotite properly, associated with secondary minerals. Secondary minerals are of iron hydroxide minerals, such as goethite and lepidochrocite, and chalcocite, hematite. General relative quantitative ratios of those minerals in decreasing order of quantity show diaphanous minerals, chalcocite, iron hydroxide minerals, pyrrhotite and hematite. Pyrrhotite, less than 80 microns long and euhedral- to subhedral-granular, is observed in chalcocite or diaphanous minerals. Chalcocite is generally observed in forms of 50 microns long, 1 millimetre the longest, replacing pyrrhotite or replaced by iron hydroxide minerals or in diaphanous minerals. Hematite is undefinedly granular of less than several microns long, subhedral- to anhedral- lathy, replaced by iron hydroxide minerals or in those minerals by sparse dissemination.

2) Sample, base metallic minerals-quartz vein ore, Mkangombe North, Mkangombe Area, number A035

Observed by unaided eye to show random dissemination and/or indistinct banded texture. Chiefly composed of quartz, limonite, covellite, malachite and etc.. Magnetism is observed in brown textural bands.

Under the microscope, the specimen is chiefly composed of iron hydroxide minerals and quartz. Primary metallic minerals consist of chalcopyrite with minor quantity of pyrite. Secondary minerals consist of iron hydroxide minerals such as goethite and lepidochrocite, maghemite, covellite and hematite. General relative quantitative ratios of those minerals in decreasing order of quantity show iron hydroxide minerals, quartz, chalcopyrite, maghematite, covellite, hematite and pyrite. Primary minerals are replaced by secondary minerals, while minerals of earlier crystallization are replaced by those of later crystallization. Chalcopyrite is observed in iron hydroxide minerals of anhedral granular forms, 300 microns long is the longest, to show a marginal replacement or fine veining/network veining replacement textures entirely by maghematite and covellite or partly by goethite and lepidochrocite. Pyrite, subhedral- or anhedral-granular, less than 30 microns long, is minorly observed sparse-disseminatedly in iron hydroxide minerals. Maghemite, shown in association with covellite, is observed in the form of marginal replacing materials of chalcopyrite or isolated disseminations in iron hydroxide minerals. Hematite, which is shown with similar behaviour to that of chalcopyrite, generally less than 10 microns long, while, 30 microns long is the longest, is generally observed isolatedly in iron hydroxide minerals in the forms of irregular xenomorph. Iron hydroxide minerals chiefly consist of goethite, minorly associated with lepidochrocite.

Under the microscope, general crystallization order of those minerals from early to late stages order is quartz-pyrite, chalcopyrite, hematite-covellite, maghemite and goethite-lepidochrocite.

3) Sample, base metallic minerals-quartz vein ore, Mkangombe North, Mkangombe Area, number A037

Coarse-grained metallic mineral crystals, about 10 millimetres long, are observed in quartz by unaided eye. Minerals with magnetism are not discernible.

Under the microscope, the specimen chiefly consists of quartz and diaphanous minerals. Primary metallic minerals consist of galena and chalcopyrite, associated with minor quantity of pyrite. Secondary minerals consists of iron hydroxide minerals, such as goethite and lepidochrocite, covellite and hematite. General relative quantitative ratios of those minerals in decreasing order of quantity show quartz, galena, chalcopyrite, iron hydroxide minerals, covellite, hematite and pyrite. Quartz is euhedral to subhedral, about 1 millimetre long in average. Galena, margins of which or cleavages are irregularly replaced by covellite, goethite and etc., is 15 millimetres long the longest. Chalcopyrite, anhedral-granular of 0.5 millimetre long the longest, is shown to be replaced by a similar mode to that in galena, i.e., replaced by covellite, goethite and etc., in crystals margins or along cleavages. Hematite, less than 500 microns long and anhedral-granular, is observed in iron hydroxide minerals in small quantity of disseminations, in banded or concentric manners with iron hydroxide minerals. Pyrite, less than 10 microns long and anhedral-granular, is observed sparse-disseminatedly in iron hydroxide minerals. Covellite with marginal replacement textures is observed to be replacing galena with iron hydroxide minerals.

Under the microscope, general crystallization order of those minerals from early to late stages order is quartz-pyrite, chalcopyrite-galena, hematite-covellite, and goethite-lepidochrocite.

4) Sample, base metallic minerals-quartz vein ore, Mkangombe North, Mkangombe Area, number A043

Chiefly composed of quartz by unaided eye, with strongly magnetic metallic minerals of irregular disseminations and speckled aggregates, in association with fine veinings of limonite.

Under the microscope, quartz grains are disseminated by primary metallic minerals, marginal and/or inner parts of which are replaced by fine veinings of covellite, maghematite and etc.. Those are further wholly intersected by fine veins of iron hydroxide minerals. General relative quantitative ratios of those minerals in decreasing order of quantity show quartz, chalcopyrite-magnetite, covellite, maghemite, iron hydroxide minerals and pyrite. Primary metallic minerals consist of chalcopyrite, magnetite and pyrite. Chalcopyrite, less than 1 millimetre long, is observed to be marginally replaced by maghemite and covellite, and further to be outer-surrounded by iron hydroxide minerals. Magnetite is irregularly anhedral, several microns long, and is isolatedly observed in quartz or chalcopyrite crystals. Iron hydroxide minerals, chiefly consist of goethite, are observed in the forms of fine veinings of 50 microns wide the largest, to replace magnetite and chalcopyrite in association with diaphanous minerals or in the forms of granules of less than 50 microns long in quartz crystals.

Under the microscope, general crystallization order of those minerals from early to late stages order is pyrite, chalcopyrite-magnetite, quartz, maghemite-covellite and goethite-lepidochrocite.

5) Sample, base metallic minerals-quartz vein ore, Mkangombe North, Mkangombe Area, number A044

A brecciated quartz ore with fragmental limonite, magnetic black minerals and fine veins of malachite and covellite by unaided eye.

Under the microscope, chiefly consists of iron hydroxide minerals and quartz. Primary metallic minerals properly consist of small quantity of pyrite and magnetite. Primary metallic minerals are replaced by secondary iron hydroxide minerals, such as goethite, lepidochrocite and etc., in undefined forms of less than 20 microns long. Hematite shows banded or colloform structures and is granularly disseminated, several microns long, in iron hydroxide minerals, such as goethite, lepidochrocite and etc.. General relative quantitative ratios of those minerals in decreasing order of quantity show quartz, iron hydroxide minerals, malachite, hematite, magnetite and pyrite. Iron minerals are observed in fragmental forms in quartz crystals. Diaphanous minerals, presumed to be of malachite, are observed to intersect quartz crystals in the forms of fine veins, 100 microns wide the largest. Those locally form concentrated parts, 0.5 millimetre wide. Covellite is properly observed concentratedly by unaided eye in cavities filled up by malachite.

6) Sample, pyrite-bearing sandstone, Jibana Area, number B006

Composed of quartz and diaphanous minerals with overall parallel bandings, associated with disseminated metallic minerals by unaided eye.

Under the microscope, the sample is chiefly composed of quartz and diaphanous minerals, as similar to an identification by unaided eye, and is disseminated by primary metallic minerals, properly consist of sphalerite and pyrite. General relative quantitative ratios of those minerals in decreasing order of quantity show quartz, diaphanous minerals, pyrite and sphalerite. Pyrite, about 200 microns long, is anhedral and undefinedly granular to replace quartz and sphalerite. Sphalerite, 300 microns long the largest, is irregularly anhedral to subhedral to be replaced by pyrite.
Under the microscope, general crystallization order of those minerals from early to late stages order is quartz-diaphanous minerals, sphalerite and pyrite.

7) Sample, pyrite-bearing petrified wood, Jibana Area, number B006'
Pyrite shows a lenticular form, 100 to 200 microns long and some 50 microns wide, or fine veining, less than 1 micron wide, or anhedral-granular aggregates of vein-form, about 200 microns long and some 0.5 micron wide. Lenticular and fine-veining forms of pyrite assemblage are extended in respective parallel directions to be considered to be of a replacement texture. Pyrite is exclusively identified as the metallic mineral in the specimen.

8) Sample, iron oxide ore, Ganze Area, number B010
Chiefly consists of hematite, with very sparse association with very fine-grained pyrite, less than 1 micron long. Diaphanous minerals, presumed to be of quartz, are observed.

9) Sample, carbonatite, Mrima-Jombo Area, number B038
Chiefly composed of white diaphanous minerals with sparse disseminations of black mineral grains with magnetism by unaided eye.
Under the microscope, black minerals are of chalcocite associated with pyrrhotite. Primary metallic minerals consist of pyrrhotite and small quantity of pyrite, while, pyrite is replaced by chalcocite. Secondary minerals are of chalcocite, hematite and iron hydroxide minerals, such as goethite and lepidochrocite. General relative quantitative ratios of those minerals in decreasing order of quantity show diaphanous minerals, chalcocite, pyrrhotite, hematite, iron hydroxide minerals and pyrite. Pyrrhotite, less than 100 microns long and euhedral- to subhedral-granular, is disseminatedly observed in diaphanous minerals. Chalcocite, about 500 microns long generally and 800 microns long the longest, shows pseudomorphs to replacing pyrite, while, marginal parts of that are replaced by iron hydroxide minerals. Hematite, less than several microns long, undefinedly granular or subhedral- to anhedral-lathy, is replaced by iron hydroxide minerals or disseminated in those.

10) Sample, iron oxide ore, Mrima-Jombo Area, number F009
Hematite and marcasite, which are with colloform-type texture in cavities and lathy, less than 100 microns long, are properly observed.
