Results of microscopic mineral identification<br>of ore specimens on polished sections

1) Sample, weathered carbonatite, Mrima-Jombo Area, number A034

Chiefly composed of white diaphanous minerals with sparse disseminations of gains or aggregates of strongly magnetic black and dark brown minerals by unaided eye.
Under the microscope, black minerals are of pyrrhotite-associated chalcopyrite, dark brown minerals ate of iton hydroxide minerals. Primary metallic minerals wholly consist of pyrrhotite properly, associated with secondary minerals. Secondary minerals are of iron hydroxide minerals, such as goethite and lepidochrocite, and chalcocite, hematite. General relative quantitative ratios of those minerals in decreasing order of quantity show diaphanous minerals, chalcocite, iron hydroxide minerals, pyrrhotite and hematite. Pyrrhotite, less than 80 microns long and euhedral- to subhedralgranular, is observed in chatcocite or diaphanous minerals. Chalcocite is generally observed in forms of 50 microns long, 1 millimetre the longest, replacing pyrrhotite or replaced by iron hydroxide minerals or in diaphanous minerals. Hematite is undefinedly granular of less than several microns longs subhedral- to anhedral- lathy, replaced by iron hydroxide minerals or in those minerals by sparse dissemination.
2) Sample, base metallic minexals-quartz vein ore, Mkangombe North, Mkangombe Area, number A035

Observed by unaided eye to show random dissemination and/or indistinct banded texture. Chiefly composed of quartz, limonite, covellite, malachite and etc.. Magnetism is observed in brown textural bands.
Under the microscope, the specimen is chiefly composed of iron hydroxide minerals and quartz. Primary metallic minerals consist of chalcopyrite with minor quantity of pyrite. Secondary minerals consist of iron hydroxide minerals such as goethite and lepidochrocite, maghemite, covellite and hematite. General relative quantitative ratios of those minerals in decreasing order of quantity show fron hydroxide minerals, quaria, chalcopyrite, maghematite, covellite, hematite and pyrite. Primary minerals are replaced by secondary minerals, while minerals of earlier crystallization are replaced by those of later crystallization. Chalcopyrite is observed in iron hydroxide minerals of anhedral granular forms, 300 microns long is the longest, to show a marginal replacement or fine veining/network veining replacement textures entirely by maghematite and covellite or partly by goethite and lepidochrocite. Pyrite, subhedral- or anhedralgranular, less than 30 microns long, is minorly observed sparse-disseminatedly in iron hydroxide minerals. Maghemite, shown in association with covellite, is observed in the form of marginal replacing materials of chalcopyrite or isolated disseminations in iron hydroxide minerals. Hematite, which is shown with similar behaviour to that of chalcopyrite, generally less than 10 microns long, while, 30 microns long is the longest, is generally observed isolatedly in iron hydroxide minerals in the forms of irregular xenomorph. Iron hydroxide minerals chiefly consist of goethite, minorly associated with lepidochrocite.

Under the microscope, general crystallization order of those minerals from early to late stages order is quartz-pyrite, chalcopyrite, hematite-covellite, maghemite and goethite-lepidochrocite.
3) Sample, base metallic minerals-quartz vein ore, Mkangombe North, Mkangombe Area, number A037

Coarse-grained metallic mineral crystals, about 10 millimetres long, are observed in quartz by unaided eye. Minerals with magnotism are not discernible.
Under the microscope, the specimen chiefly consists of quartz and diaphanous minerals. Primary metallic minerals consist of galena and chalcopyrite, associated with minor quantity of pyrite, Secondary minerals consists of iron hydroxide minerals, such as goethite and lepidochrocite, covellite and hematite. General relative quantitative ratios of those minerals in decreasing order of quantity show quartz, galena, chalcopyrite, iron hydroxide minerals, covellite,
hematite and pyrite. Quartz is ethedral to subhedral, about 1 millimetre long in avarage. Galena, matgins of which or cleavages are irregularly replaced by covellite, goethite and etc., is 15 millimetres long the longest. Chalcopyrite, anhedral-gtanular of 0.5 millimetre long the longest, is shown to be replaced by a similar mode to that in gatena, i.e., replaced by covellite, goethite and etc., in crystals margins or along cleavages. Hematite, less than 500 microns long and anhedral-granular, is observed in iron hydroxide minerals in small quantity of disseminations, in banded or concentric manners with iron hydroxide minexals. Pyrite, less than 10 microns long and anhedral-granular, is observed sparsedisseminatedly in iron hydroxide minerals. Covellite with marginal replacement textures is observed to be replacing galena with iron hydroxide minerals.
Under the microscope, general crystallization order of those minerals from early to late stages order is quartz-pyrite, chalcopyrite-galena, hematite-covellite, and goethite-lepidochrocite.

Sample, base metallic minerals-quartz yein ore, Mkangombe North, Mkangombe Area, number A043
Chefly composed of quartz by unaided eye, with strongly magnetic metalic minerais of irregular disseminations and speckled aggregates, in association with fine veinings of limonite.
Under the microscope, quartz grains are disseminated by primary metallic minerals, marginal and/or inner patts of which are replaced by fine veinings of covellite, maghematite and etc.. Those are further wholly intersected by fine veins of iron hydroxide minerals. General relative quantitative xatios of those minerals in deereasing oxder of quantity show quartz, chalcopyrite-magnetite, covellite, maghemite, iron hydroxide minerals and pyrite. Primary metallic minerals consist of chalcopyrite, magnetite and pyxite. Chalcopyrite, less than 1 millimetre long, is observed to be marginally replaced by maghemite and covellite, and further to be outer-surrounded by iron hydroxide minerals. Magnetite is irregularly anhedral, several microns long, and is isolatedly observed in quartz or chalcopyrite crystals. Iron hydroxide minerals, chiefly consist of goethite, are observed in the forms of fine veinings of 50 microns wide the largest, to replace magnetite and chalcopyrite in association with diaphanous minerals or in the forms of granules of less than 50 microns long in quartz crystals.
Under the microscope, general crystallization order of those minerals from early to late stages order is pyrite, chal-copyrite-magnetite, quartz, maghemite-covellite and goethite-lepidochrocite.

## 5) Sample, base metallic minerals-quartz vein ore, Mkangombe North, Mkangombe Area, number A044

A brecciated quartz ore with fragmental limonite, magnetic black minerals and fine veins of malachite and covellite by unaided eye.
Under the microscope, chiefly consists of iron hydroxide minerals and quartz. Primary metalic minerals properly consist of small quantity of pyrite and magnetite. Primary metallic minerals are replaced by secondary iron hydroxide minerals, such as goethite, lepidochrocite and etc., in undefined forms of less than 20 microns long. Hematite shows banded or colloform structures and is granulatly disseminated, several microns long, in iron hydroxide minerals, such as goethite, lepidochrocite and etc.. General relative quantitative ratios of those minerals in decreasing order of quantity show quartz, iron hydroxide minerals, malachite, hematite, magnetite and pyrite. Iron minerals ate observed in fragmental forms in quartz crystals. Diaphanous minerals, presumed to be of malachite, are observed to intersect quartz crystals in the forms of fine veins, 100 microns wide the largest. Those locally form concentrated parts, 0.5 millimetre wide. Covellite is properly observed concentratedly by unaided eye in cavities filled up by malachite.
6) Sample, pyrite-bearing sandstone, Jibana Area, number $B 006$

Composed of quartz and diaphanous minerals with overall parallel bandings, associated with disseminated metallic minerals by unaided eye.

Under the microscope, the sample is chiefly composed of quartz and diaphanous minerals, as similar to an identification by unalded eye, and is disseminated by primary metallic minerals, properly consist of sphaterite and pyrite. General relative quantitative ratios of those minerals in decreasing order of quantity show quartz, diaphanous minerals, pyrite and sphalerite. Pyrite, about 200 microns long, is anhedral and undefinedly granular to replace quartz and sphalerite. Sphalerite, 300 microns long the largest, is irregularly anhedral to subhedral to be replaced by pyrite.

Under the microscope, general crystalization order of those minerals from early to late stages order is quartz-diaphanous minerals, sphalerite and pyrite.
7) Sample, pyrite-beaing petritied wood, Jibana Area, number B006'

Pyrite shows a lenticular form, 100 to 200 microns long and some 50 microns wide, or fine veining, less than 1 micron wide, or anhedral-granular aggregates of vein-form, about 200 microns long and some 0.5 micron wide. Lenticular and fine-veining forms of pyrite assemblage are extended in respective parallel directions to be considered to be of a replacement texture. Pyrite is exclusively identified as the metallic mineral in the specimen.
8) Sample, iron oxide ore, Ganze Area, number $\mathbf{B 0 1 0}$

Chiefly consists of hematite, with very sparse association with yery fine-grained pyrite, less than 1 micron long. Diaphanous minerals, presumed to be of quatz, are observed.
9) Sample, carbonatite, Mrima-Jombo Area, number B038

Chiefly composed of white diaphanous minerals with sparse disseminations of black mineral grains with magnetism by unaided eye.
Under the microscope, black minerals are of chaleocite associated with pyrrhotite. Primary metallic minerals consist of pyrrhotite and small quantity of pyrite, while, pyrite is replaced by chalcocite. Secondary minerals are of chalcocite, hematite and iron hydroxide minerals, such as goethite and lepidochrocite. General relative quantitative ratios of those minerals in decreasing order of quantity show diaphanous minerals, chalcocite, pyrrhotite, hematite, iron hydroxide minerals and pyrite. Pyrshotite, less than 100 microns long and euhedral- to subhedral-granulax, is disseminatedly observed in diaphanous minerals, Chalcocite, about 500 microns long generally and 800 microns long the longest, shows pseudomorphs to replacing pyrite, while, marginal parts of that are replaced by iron hydroxide minerals. Hematite, less than several microns long, undefinedly granular or subhedral- to anhedral-lathy, is replaced by iron hydroxide minerals or disseminated in those.
10) Sample, iron oxide ore, Mrima-Jombo Area, number F009

Hematite and marcasite, which are with colloform-type texture in cavities and lathy, less than 100 microns long, are properly observed.
