

5.4 Cropping Intensity of Paddy

Cropping area of each scheme is estimated from topographical map surveyed during the Study. Ratio of paddy fields both wet and dry season is calculated in the table II-8. Mean cropping ratio between wet and dry season at North Sumatra is 84 %, and 72 % for South Sulawesi and 50 % for NTB respectively.

As to the NTB province, the lowest ratio is shown due to little rainfall in dry season in Sumbawa island especially. As the results of calculation, cropping intensities of paddy field are as below;

North Sumatra	;	184 %
South Sulawesi	;	172 %
NTB	;	150 %

Above value shows comparatively large intensity but these intensity own to their river discharge itself. On the other hand the inventory data on the ratio of planting area was gained as bellow;

North Sumatra	;	LD	;	75.3 % of wet paddy area
		VI	;	61.2 %
South Sulawesi	;	LD	;	29.3 %
		VI	;	62.4 %
NTB	;	LD	;	0 %
		VI	;	6.6 %

From the above both data, planning cropping ratio between wet and dry season is assumed considering hydrological analysis.

5.5 Other Basic Dimension for Irrigation Plan

(1) Intake Discharge and Canal Discharge

Discharge of Intake and distribution canal are shown in Table discharge and canal discharge of Table II-9.

(2) Work Quantity for 30 Representative Schemes

Work quantity for 30 representative schemes by item and classification are shown in Table II-10.

(3) Planning Area of Land Development

Planning area of land development in the three provinces is described in Table II-11.

(4) Land Use of Representative Schemes

Land use area of present condition and planing condition in each representative scheme are calculated by topographical maps surveyed actually (map scale 1:2,000) and land use maps. Refer to the Table II-12.

APPENDIX-III

METEOROLOGY AND HYDROLOGY

APPENDIX III METEOROLOGY AND HYDROLOGY

1. METEOROLOGY

The meteorological data in the Study area are arranged at many observation stations of the Bureau of Weather, Provincial Services for Public Works and Agriculture (DPU and DIPERTA), and other agencies. It is difficult to collect all of the data during a short period because of the enormous amount. Thus the data especially for rainfall in the limited areas are collected. Table III-1 to III-3 show the number of observation stations by province for reference data.

1.1 Rainfall

(1) Collected Data

The data at a rural extension center (BPP) located in the neighborhood of each scheme for the latest five (5) years are used as the data for the scheme. Usually, ten day data arranged by BPP using daily data are sent to the Provincial Agricultural Services (PRAS) and PRAS has the custody of monthly data compiled from ten day data.

(2) Rainfall in Dry and Wet Seasons

The ratio between average monthly rainfall data in the dry season and those in the wet season is arranged as follows:

RATIO OF AVERAGE RAINFALL IN DRY SEASON /AVERAGE RAINFALL IN WET SEASON									
NORTH SUMATRA			SOUTH SULAWESI			WEST NUSA TENGGARA			
WET SEASON RAINFALL mm	DRY SEASON RAINFALL mm	RATIO DRY/WET	WET SEASON RAINFALL mm	DRY SEASON RAINFALL mm	RATIO DRY/WET	WET SEASON RAINFALL mm	DRY SEASON RAINFALL mm	RATIO DRY/WET

The table shows that rainfall in the dry season is not expected in West Nusa Tenggara because the dry and wet seasons are clearly specified. North Sumatra province has rainfall more than 100 mm even in the dry season and the region with monthly rainfall more than 200 mm in the dry season. In North Sumatra province, the rainfall in the dry season is not so different from those in the wet season. In South Sulawesi province, the monthly rainfall in the wet season is comparatively big and reaches to more than 300 mm.

The ratio between the rainfall in the wet season and those in the dry season may suggest the ratio between the paddy cultivation areas in both seasons in the schemes taking water from rivers with small discharge.

1.2 Air Temperature and Relative Humidity

There are almost no annual difference in each province with reference to the average yearly air temperature and relative humidity as shown in Table III-4 and Table III-5. The air temperature ranges from 23°C to 31°C and the relative humidity is at the level of 80%.

2. HYDROLOGY

2.1 Result of Inventory Survey

The following tables show the results arranged and analyzed using available data by inventory item on the schemes with their water source facilities on river. (Refer to Table III-6 ~ Table III-11)

2.2 Specific Discharge

The analysis of discharge is carried out referring to the hydrological data arranged by BTA 155, DGWRD using the report on Regional Physical Planning Program for Transmigration (RePPPProT) of the Ministry of Transmigration.

Specific discharge in the wet and dry season are estimated dividing areas into certain regions from hydrological view points by each province. The specific discharges in the dry season are obtained by averaging the minimum discharge data on monthly average basis by region. Those in the wet season are gotten by averaging the annual mean discharge by region. However, the specific discharge in Sumbawa island are estimated at the average of four or five months' data in the wet season because the discharge in the dry season is extremely small.

In the above, the hydrological regions are taken as two (2) regions in north and south areas of North Sumatra, three (3) in north, central and south areas of South Sulawesi and two (2) of Lombok and Sumbawa Islands of West Nusa Tenggara.

2.3 Evaluation of Water Availability

It is necessary to estimate river discharge for each scheme because the water availability is the decisive factor to decide the irrigable area in each scheme. Although the observed data are the best data for the estimation, almost no observed data during the long period is found in almost all the schemes. Besides, it is difficult to estimate catchment areas and thus it is almost impossible to estimate river discharge by specific discharge and catchment area.

Consequently, the evaluation of water availability is carried out by the following method.

(1) Annual conditions

- River discharge data, if any, in the inventory survey result is used.
- If no data is found in the inventory survey result, river discharge is estimated by the assumed discharge per unit width of river.
- Intake discharge is assumed to be 80% at maximum of river discharge.
- Unit water requirement data, if any, in the inventory survey result is used. In the case that no data is found, or the data is not reliable, the following values are used.

Province	Water Requirement in wet Season	Water Requirement in Dry Season
North Sumatra	1.2 ℓ /sec/ha	1.5 ℓ /sec/ha
South Sulawesi	1.2	1.5
West Nusa Tenggara	1.3	1.5

- Cultivated area in the dry season is taken as the average data in the inventory survey result.

Province	LD	VI
North Sumatra	75%	61%
South Sulawesi	30%	62%
NTB Lombok	60%	60%
Sumbawa	5%	5%

(2) Estimation of discharge per unit width of river

The discharge per unit width (m) of river is obtained using the river discharge data and river width considered to be reliable in the inventory survey result.

In Sumbawa, however, the unit discharge is inferred by the estimated discharge for Lombok and the ratio of the specific discharge because no available data is found.

The result of the estimation is as follows:

Province	Wet Season	Dry Season
North Sumatra	340 ℓ/m	160 ℓ/m
South Sulawesi	260	90
NTB Lombok	60	20
Sumbawa	55	5

(3) Point for evaluation

The ratios by season between the irrigated area and the irrigable area estimated by the possible intake discharge are obtained respectively and the water availability is evaluated by the points obtained using the following division. The full point is 15.

Wet season	Ratio ≥ 1.0 10 points
	Ratio < 1.0 Ratio \times 10 points
Dry season	Ratio ≥ 1.0 5 points
	Ratio < 1.0 Ratio \times 5 points

The results are shown in Table III-18 to Table III-20.

APPENDIX-IV

IRRIGATION AND DRAINAGE

APPENDIX IV. IRRIGATION AND DRAINAGE

1. FIELD SURVEY

Land development schemes and village irrigation schemes in North Sumatra Province (9 districts), South Sulawesi Province (18 districts), and West Nusa Tenggara (6 districts) were surveyed. Duration of the survey was one (1) month for preliminary field survey, two (2) months for selecting representative schemes, and two and half months (2.5) for detailed survey of the representative schemes.

At the starting time of entrusting survey for representative schemes, the schemes to be entrusted were divided into thirty(30), and the surveys were carried out under the instruction of other specialists.

In Phase I, a field survey was conducted for about 80 schemes in the objective inventory survey schemes, about 980. Further, a field survey for the representative schemes which were grouped in about 30 was made in Phase II. The survey was accentuated in intake facilities, conveyance facilities, and possibility of land reclamation. The results of study and analysis were reflected in the whole schemes.

Through the field survey and inventory survey, the principle findings are as follows:

- (1) Village irrigation scheme has the possibility of considerable extension of paddy field as well as rehabilitation works.
- (2) There still exist some schemes which are not identified to be village irrigation scheme in inventory survey.
- (3) It was found that the decisive reason to delay the land development was due to the shortage of irrigation water in many cases. In the case where the swamp or forest are selected for development area, the development cost becomes high, which causes the suspension of land development. However, it may account for small ratio.

- (4) In village irrigation scheme, the life year of irrigation facilities is very short, perhaps five(5) years. It may result from insufficient survey, investigation, design, and small investment.

2. CONSIDERATIONS OF PLANNING

2.1 Evaluation of Potential Scheme

Concerning the potentiality of land development, it can not be expected very much by such reasons as water shortage, change in the category of land, damage of principal facilities, etc.

In village irrigation scheme, there is no potential new scheme to be developed largely because of scheme size.

Accordingly, it is necessary to expand paddy formation area in proportion to water source discharge, to raise the facility level by rehabilitation of the existing facilities, and to carry out the additional work following the extension of paddy formation area.

2.2 Problems on Planning

- (1) Since no topographical map is available in village irrigation scheme, survey is required for planning of individual scheme in advance.
- (2) In village irrigation, water is derived from river through plural intake facilities in accordance with customary practice. Therefore, a scheme area should be decided after full negotiation with villages in development planning.
- (3) Durable duration of present intake facilities is considered to be five(5) years at most, but one(1) year if the worst happens. Therefore, to fulfil their function over long period, the facilities should be improved.
- (4) The acreage based on inventory survey appears to be rather larger comparing those of detailed survey result. Thus, they should be re-evaluated in as much as 70%.

2.3 Potential Acreage of Paddy Field Development

Through survey results of 30 representative schemes, the potential acreage of paddy field is decreased to 70% which is used for inventory survey data and planning as in the following table:

Item	Schemes	Present		Plan		Potential Schemes.	
		Paddy field	Rainfed	Paddy field	Rainfed	Area	No.
	nos	ha	ha	ha	ha	ha	nos
Inventory Listed	795	70,600	44,000	108,300	21,400	15,000	240
Potential evaluated	795	49,400	30,800	75,800	15,000	10,500	240
Implement.(ID) Plan	30	-		2,300		2,300	30
	(VI)310	17,000		28,100		2,000	67

2.4 Others

(1) Types of Water Source Works

According to the inventory survey, the water source of which about 85 % depends on river, and about 10% on spring. The existing facilities consist of headworks(70%), free intake(16%), dams, small reservoirs, pumps, etc.

(2) Topography of Schemes

The lands of schemes slope gently with an average fall of less 5% or with 5-10%, which occupy 86% of the whole schemes. As for a scale of schemes, they fall under the areas of 25 ha-250 ha according to the screening criteria of the initial inventory survey. The land of more than 250 ha is considered to an exception. Most of the schemes in three(3) provinces fall under the areas of 50-100 ha.

(3) Division of Types of Constructions

Types of constructions are paddy field formation works, improvement and renewal of intake facilities, and canal systems, repairing of peripheral facilities, additional works, etc. Concerning the principal facility such as headworks, judgement as to whether or not the facility is required for rehabilitation or renewal, or the facility is in good condition, was made based on the results of inventory survey.

3. BASIC CONCEPT OF FACILITY PLAN

3.1 Size of Planned Schemes

The average acreage of planned paddy field per scheme is as follows:

Province	LD Scheme	VI Scheme	Average
	ha/nos	ha/nos	ha/nos
North Sumatra	142	87	98
South Sulawesi	93	89	89
NTB	192	100	103

3.2 Irrigation and Drainage Facilities

(1) General

In order to achieve agricultural development in planned schemes, the construction of the following infrastructures and improvement of agricultural supporting organization are required:

- a) Construction of irrigation network consisting of a weir, linking, main, secondary, delivery and field canals.
- b) Construction of secondary drainage canal and facilities.
- c) Construction of inspection road and link road consisting of trunk road and farm road.
- d) Construction of tertiary network consisting of tertiary and quaternary canals, tertiary and quaternary drains, farm road, and related structures.
- e) Reclamation of new farm lands.
- f) Maintenance of irrigation and drainage facilities, and
- g) Improvement of the present agricultural supporting services.

(2) Improvement of Irrigation Efficiency

The target of irrigation efficiency used in planning is as follows:

Main Canal	: 90%
Secondary Canal	: 90%
Tertiary Canal	: 70%

Overall Efficiency : 50%

(3) Planting Area of Paddy Field

Rainy Season Paddy	:	100%	
<hr/>			
Dry Season Paddy	:	Present	Future
North Sumatra	:	50%	60%
South Sulawesi	:	50%	60%
Lombok Island	:	50%	60%
Sumbawa Island	:	0%	5%

(4) Scale of Irrigation Block

- Tertiary Unit : 50-100 ha
- Quaternary Unit : 8- 15 ha
(tertiary unit can cover from 15 ha to 150 ha due to topographical condition)
- Tertiary Canal Length : Less than 1,500 m
- Quaternary Canal : Less than 500 m
- Quaternary Drainage : Interval less than 300m
- Plot to plot irrigation : Inter terrace flow should be restricted to about 8 rice fields or 300 m maximum length

3.3 Standard Design of Major Structure

Attached drawings show standard design of major structures for rehabilitation, improvement and/or replacing of irrigation and drainage structures. Names of attached drawings are as follows:

- a. Standard design of weir body
The following five(5) types are adopted.
 - 1. Wet masonry fixed weir type
 - 2. Tyroller type
 - 3. Gabion type
 - 4. Protect type by wet masonry cover
 - 5. Masonry cut-off & gabion type
- b. Standard design of weir plan & section
- c. Standard pump station
- d. Standard section of irrigation canal
- e. Standard section of drainage canal

APPENDIX-V

SOIL AND LAND USE

APPENDIX-V SOIL AND LAND USE

1. GENERAL

In Appendix-V, soil and land use features are described regarding to the objective provinces, the Project areas, and the representative scheme areas, in turn. The provincial overviews are based on the statistical data and existing maps representing soils and land use. As for the project area, the results of the inventory survey conducted by the Study Team provide general information, although the data are not always reliable. As to the representative schemes, soil investigation and land use mapping were carried out within the Study. The results of these works show detail conditions on the sites, moreover contribute on future land use plans on the schemes.

2. SOIL

2.1 Provincial Overview of Soil

Soils are regarded as one of main factors which determine how land can be used. There are numerous large-scale soil maps for the country's regions but no for the whole country in Indonesia. The criteria or category of soils are not uniformed for long time. The Research Center for Soil and Agro-climate is now preparing comprehensive criteria and category for soil, but the works are still on the way. The existing criteria are basically in line with FAO-UNESCO system (refer to Table V-1). Although there are slight differences in the soil classification, basic information of soils comes from provincial soil maps prepared by National Land Agency (BPN) in the province level.

The soil maps covering whole provincial area are slightly modified and presented in Fig. V-1, V-2, and V-3 by province, and soil distribution is shown in Table V-2.

2.2 Soil in the Project

Soil maps in the three provinces are available to understand general condition of soils for this project scattered in whole provincial area. Soil name on each survey area can be distinguished by overlaying location maps on soil maps. General soil maps are attached as Fig. V-1, V-2 and V-3. Soil names on these maps are in line with Indonesian soil classification system that is based on FAO-Unesco soil units. The major soils in the three provinces are as follows.

Sumut:	Organosol, Alluvial, Regosol, Grumusol, Andosol, Podosolik, Latosol
Sulsel:	Alluvial, Gley, Latosol, Regosol, Grumusol, Rensina, Podosolik, Mediteran
NTB:	Mediteran(23.4%), Regosol(19.4%), Alluvial(7.3%), Grumusol(5.1%), Latosol(2.0%)

Results of the inventory survey on soil name, ground slope, soil suitability for paddy and secondary crops (palawija) and other physical conditions at the project areas are summarized as shown in Table V-3. Soil distribution on the projects has some difference among the provinces. Soils which have over 10 % share in number of sub projects are listed as follows by provinces (refer to Fig. V-4).
