# Appendix: Statistical Analysis for Crop Cutting Test of LowLand Paddy

Everybody wants to increase the yield of paddy and also to know which factor is a key factor for increasing paddy yield, namely irrigation or fertilizer. But is it true and what type of irrigation is the most favourable for increasing yield and how much amount of fertilizer application is the most effective for increasing yield? To solve and to make clear the question, a many data of field experiment and analysis of these data are required.

Fortunately enough data of crop cutting test of lowland paddy covering whole Indonesia are now available for analysis of the effect of irrigation and fertilizer application on the paddy yield. Followings show the procedure of statistical analysis of the data of crop cutting test to make clear the contribution of each type of irrigation system and that of the amount of fertilizer application to the paddy yield, and the interaction effect of the type of irrigation facility and the amount of fertilizer application to the paddy yield.

#### Data source

Central Bureau of Statistics (CBS) has carried out a crop cutting survey of paddy for the first crop season in 1991 with assistance of Ministry of Agriculture and stored those data into micro computer, but not all of them. JICA-FIDP team requested CBS the sample data of the crop cutting test on May 1992 and received 11,261 records of the complete data of the crop cutting test by several diskettes on early July 1992. Many information such as province, kabupaten, kecamatan, irrigation type, fertilizer name and quantity, pesticide name and quantity, intensification programme and grain weight per unit area (kg per 6.25m<sup>2</sup>) are recorded in the data.

#### **Data Screening and Preprocessing**

Before processing the data, each sample was assessed by following criteria and discard extraordinary or insufficient data.

1. data which has not complete information are omitted

2. samples in which grain weight of paddy per plot under each intensification programme are more than following standard, are eliminated

Programme	weight (kg/6.25m <sup>2</sup> )
INSUS	6.30
INMUM	5.50
Non program	4.50

3. samples in which total quantity of fertilizer is more than 800 kg/ha should be eliminated

By application of above criteria, 8,981 samples were selected for further statistical analysis.

In addition to the two factors, irrigation and fertilizer, the province code, intensification programme and yield are extracted from the selected samples and then each data were arranged as shown below, for example;

Province Code	Irrigation Type	Total Fertilizer (kg/ha)	Intensification Program	Yield (ton/ha)
12	1	465	ls	5.65
31	2	120	ĺm	4.75
52	5	50	N	3.52
. :	:	•	•	:
	•	•	•	
•.	•	• • •	•	•
:	:	:	•	

[Yield] is converted from the data of the crop cutting test (kg/6.25 m<sup>2</sup>) to the grain weight per one hector (ton/ha).

[Irrigation Type] shows the type of irrigation as tabulated below

No.	Туре	
1	Technical irrigation	
2	Semi-technical irrigation	
3	Simple irrigation	
4	Village irrigation	
5	Rainfed (no irrigation)	

Following table shows the [Province Code] and its province name.

Code	Province Name	Code	Province Name   Code   I		Province Name
11	D.I. Aceh	32	Jawa Barat	62	Kalimantan Tengah
12	Sumatera Utara	33	Jawa Tengah	63	Kalimantan Selatan
13	Sumatera Barat	34	D.I. Yogyakarta	64	Kalimantan Timur
14	Riau	.35	Jawa Timur	71	Sulawesi Utara
15	Jambi	51	Bali	72	Sulawesi Tengah
16	Sumatera Selatan	52	Nusa Tenggara Barat	73	Sulawesi Selatan
17	Bengkulu	53	Nusa Tenggara Timur	74	Sulawesi Tenggara
18	Lampung	54	Timor Timur	81	Maluku
31	D.K.I. Jakarta	61	Kalimantan Barat	82	Irian Jaya

[Intensification Programme] is classified into three category namely;

Is: INSUS Programme, Im: INMUM Programme and

N: Non Programme.

[Total Fertilizer] is a total quantity of fertilizers including Urea, TSP, ZPT/PPC etc. This item has values of numeric measurements and not classifications number or character. This item was converted to classification number for further factorial analysis. In this analysis, total amount of fertilizer were classified into following 8 levels at ascending order.

Level	Total amount of fertilizer (kg/ha)	Level	Total amount of fertilizer (kg/ha)
i	0.	5	351 ~ 450
2	1 ~ 150	6	451 ~ 550
3	151 ~ 250	. 7	551 ~ 650
4	251 ~ 350	8	651 ~ 800

Then the data was converted in new column of [Total Fertilizer Level] like as follows. All the data are shown in Table B.1

Province Code	Irrigation Type	Total Fertilizer (kg/ha)	Intensification Program	Yield (ton/ha)	Total Fertilizer Level
12	1	465	İs	5.65	7
31	2	120	lm	4.75	3
52	5	50	N	3.52	2
	:	;	•	;	:
	· •	:	;	: :	:
:	1	:	:	;	•

Now the data is ready to analysis.

### Statistical analysis

### Q-1 Which irrigation type contributes to get more yield?

Calculation of mean yield and variation of yield for each irrigation type may answer this question. Calculation results and plotted all the data are shown below.

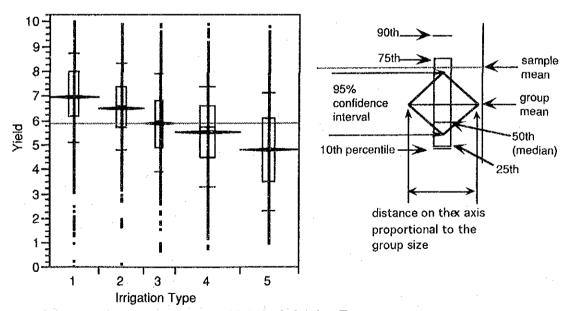

Figure B.1 Yield by Irrigation Type

At a glance, Type 1 (Technical Irrigation System) provides the highest mean yield, 6.955 ton/ha. The mean yield (ton/ha) of other irrigation type is shown below together with the number of samples.

Туре	number	Mean
1	1774	6.95533
2	1673	6.50726
3	1093	5,89790
4	2328	5.50795
5	2113	4.80108

#### Q-2 Large amount of fertilizer brings more yield?

Same as above, the mean yield under each fertilizer level are calculated and shown below.

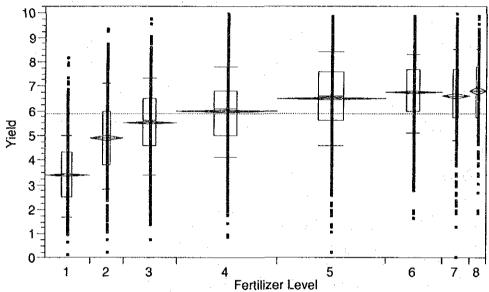

Figure B.2 Yield by Fertilizer Level

Level	number	Mean
1	921	3.41140
2	679	4.89308
3	1091	5.48836
4	2059	5.95585
- 5	2218	6.52038
6	1127	6.73372
7	563	6.57691
8	323	6.79752

Above figure implies that there is positive correlation-ship between the fertilizer level and yield. Further discussion on the relationship between the fertilizer level and yield will be presented in later Section "Regression Analysis"

At a glance of Figure B.1, the contribution of technical irrigation or semi technical irrigation system to paddy yield is much higher than that of simple or village irrigation system. The amount of fertilizer application in technical or semi-technical irrigation system, however, is much higher than that of other irrigation type, this implication is doubtful because **Q-2** resulted that the more the fertilizer, the more the yield was got. Then next question is

### Q-3 Is there a difference in the dosage of fertilizer application among the irrigation type?

Following data plot give an answer to this question. The answer is that the amount of fertilizer application increases with an upgrading of irrigation facility.

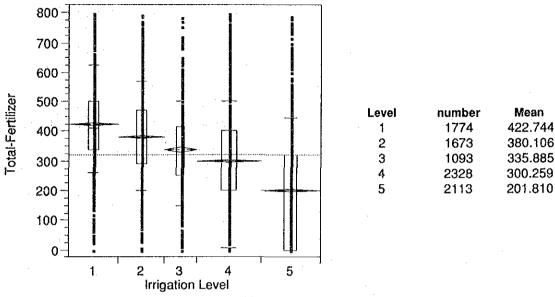

Figure B.3 Total Fertilizer by Irrigation Type

Then, it can be assumed the water (irrigation) may have no contribution to increase the yield of lowland paddy. But this assumption is true or not? Above test can not consider the interaction effect of these two factors, fertilizer and water, on the yield. In Q-1, the effect of fertilizer on the yield was disregarded and in Q-2, the effect of water was also disregarded. To solve this question, a factorial analysis of variance method have been employed as described below.

### Q-4 Irrigation and fertilizer contribute to increase paddy yield?

A factorial analysis of variance is applied under the hypothesis that there is no difference in the yield among the models, and the results of the analysis are shown bellow.

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Ratio	Probability>F
Model	. 49	10,392.8	212.1	111.0	0.0000
Irrigation level	-4	598.3	149.6	78.3	0.0000
Fertilizer level	7	1,693.4	241.9	126.48	0.0000
Irrigation * Fertilize	er 28	202.6	7.234	3.782	0.0000
Others	10	7,898.6		•	
Error	8,931	17,067.8	1.91		
C Total	8,980	27,460.7			

Source: JICA-FIDP team calculation based on the crop cutting data by CBS.

Sum of Squares (SS) quantifies the variation in yield. C total is the corrected total SS. It is divided into the SS for Model and SS for Error.

The SS for Model shows the variation in the yield among the models explained by the analysis of variance and the SS for Error is the remaining or unexplained variation.

A Mean Square is a sum of squares divided by its associated degree of freedom (DF).

The **F Ratio** is the model mean square divided by the error mean square.

F Ratio can be used as an index which determine the difference in the yield among the models is resulted from treatment or not, at a definite significant (probability) level.

This result shows that the hypothesis is rejected at the probability of more than 99.99%, because the hypothesis is supported at a probability of less than 0.00%. Therefore, the difference in the paddy yield under the different irrigation type and the different rate of fertilizer application is expected at a probability of more than 99.99%. Thus the irrigation facility and amount of fertilizer affect the paddy yield, significantly.

#### Q-5 Is there an overall difference in yield between irrigation type?

Factorial analysis of variance on paddy yield provides the following tables which shows the effect of irrigation type on the paddy yield can be made. There is a significant difference in the yield among the irrigation types at probability of more than 99.99%.

**Analysis of Variance** 

Sum of Squares	F Ratio	DF	Prob.>F
381.90426	49.9593	4	0.0000

**Least Squares Means** 

	2040, 04 44.00 1104.10						
Level	Least Sq Mean	Std Error	Mean				
1	6.367311747	0.0861808569	6.95533				
2	6.252016963	0.0694919784	6.50726				
3	5.908452107	0.1034253661	5.89790				
4	5.446003267	0.0554523304	5,50795				
5	5.260296204	0.0608479552	4,80108				

From above table following matrix of the difference in mean yield is made:

	1	2	3	4	5
1	0.000				
2	-0.115	0.000			~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
3	-0.459	-0.344	0.000		
4	-0.921	-0.806	-0.162	0.000	
5	-1.107	-0.992	-0.648	-0.186	0.000

Significant level (probability) of the difference in mean yield among different irrigation type is tested by using Fisher's least-significant-difference test and results is shown in following matrix.

	1	2	. 3	4	5
1	1.000				
2	0.298	1.000			
3	0.001	0.006	1.000		
4	0.000	0.000	0.000	1.000	:
5	0.000	0.000	0.000	0.024	1.000

The answer to the question of " Is there an overall difference in yield between irrigation type?" can be made as following matrix with a probability at more than 95%..

	1	- 2	3	4	5
1	-				
2	No	-			····
3	Yes	Yes	*		
4	Yes	Yes	Yes	-	
5	Yes	Yes	Yes	Yes	-

The paddy yield under the different irrigation type is significantly different with a probability at 95%, except between Type 1 and Type 2. In other words, there is a difference in the mean yield among the different irrigation type except between under Technical Irrigation System and Semi-Technical Irrigation System. The paddy yield is the highest under Technical and Semi-Technical irrigation system followed by simple irrigation, village irrigation and non irrigation.

# Q-6 Is there an overall difference in yield between fertilizer level?

Following tables show the effect of fertilizer application on the paddy yield. There is also found a difference in the yield among under different amount of fertilizer application at a probability of more than 99.99%.

	Analysis of Variance							
1	Sum of Squares	F Ratio	DF	Prob.>F				
-	1693.4336	126.4820	7	0.0000				

#### Least Squares Means

Level	Least Sq Mean	Std Error	Mean
1	4.016900531	0.1255855749	3.41140
2	5.040115724	0.0649774315	4.89308
3	5.667035333	0.0489576054	5.48836
4	6.016195208	0.0312855079	5.95585
5	6.437375330	0.0312275714	6.52038
6	6.564188301	0.0455536923	6.73372
7	6.303772830	0.0666881565	6.57691
8	6.605734236	0.0938296007	6.79752

From above table, following matrix of the difference in the mean yield is produced:

	1	2	3	4	5	6	7	8
1	0.000							
2	1.023	0.000						and the second s
3	1.650	0.627	0.000		ATWATENAN YEATHYRAINTE			
4	1.999	0.976	0.349	0.000				
5	2.420	1.397	0.770	0.421	0.000			
6	2.547	1.524	0.897	0.548	0.127	0.000		
7	2.286	1.264	0.637	0.288	-0.134	-0.260	0.000	
8	2.589	1.566	0.939	0.590	0.168	0.042	0.302	0.000

Fisher's least-significant-difference test gives following probabilities.

	1	2	3	4	5	6	7	8
1	1.000							
2	0.000	1.000						
3	0.000	0.000	1.000					
4	0.000	0.000	0.000	1.000				
5	0.000	0.000	0.000	0.000	1.000			
6	0.000	0.000	0.000	0.000	0.022	1.000		
7	.0.000	0.000	0.000	0.0001	0.070	0.001	1.000	·
8	0.000	0.000	0.000	0.000	0.089	0.690	0.009	1.000

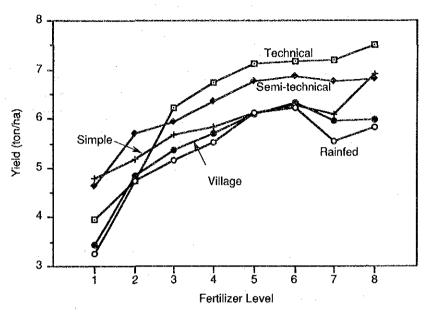

Then the answer to the question of " Is there an overall difference in yield between fertilizer level?" is summarized following matrix:

	1	2	3	4	5	6	7	8
1								
2	Yes							
3	Yes	Yes						
4	Yes	Yes	Yes	27.1	:	: .		
5	Yes	Yes	Yes	Yes				
6	Yes	Yes	Yes	Yes	Yes			
7	Yes	Yes	Yes	Yes	No	Yes		
8	Yes	Yes	Yes	Yes	No	No	Yes	

The hypothesis is rejected by this analysis with a probability at more than 95%. Therefore the more the fertilizer, the more yield is obtained, however, there is no difference in mean yield between level 5 or 6 (350~550 kg/ha) and level 8 (650~800 kg/ha). Which is economical if level 5 or 6 get the same yield as level 8?

### Q-7 Is there any interaction effect of Irrigation type and Fertilizer level on paddy yield

To check the interaction effect of Irrigation level and Fertilizer level on paddy yield, following figure was made. The yield values used in the figure are obtained by the calculation of the least squares mean of yield

Note: Fertilizer level is shown in page Appendix B-3

Figure B.4 Effect plot Between Fertilizer Level and Irrigation Type

From above graph following implication may withdraw

1 In the case of the amount of fertilizer application being less than level 3, there is no definite relationship between irrigation type and paddy yield.

In the case of the amount of fertilizer application being more than level 3,

paddy yield increases with a grade of irrigation facility, however, there is no difference in paddy yield among Simple Irrigation, Village Irrigation and rainfed, in the case of fertilizer application being level 4,5 and 6.

The yield under Technical and Semi-Technical Irrigation increase in parallel at fertilizer level at more than 3 and the yield is always higher for Technical Irrigation than for semi-technical at the same fertilizer level.

4 Fertilizer contributes for increasing yield in fact, but irrigation also contributes to increasing yield. For example, at fertilizer level 5 there is found more than one ton per ha of yield difference between Simple, Village Irrigation or rainfed and Technical Irrigation.

Technical Irrigation is the most recommendable irrigation type in the case of a

large amount of fertilizer being able to apply.

#### Q-8 Intensification program work well or not?

Figure B 2.5 shown below may give an answer to this question. INSUS programme has attained more yield than INMUM and non-programme, and INMUM programme provides more yield than non-programme.

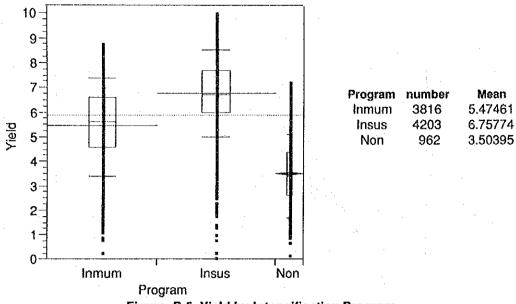

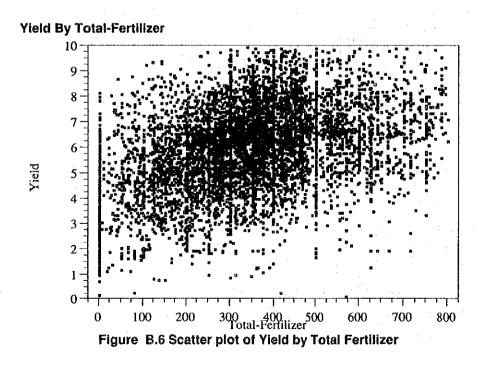

Figure B.5 Yield by Intensification Program

## Regression analysis

Simple regression analysis was made to know the relationship between amount of fertilizer and paddy yield. Two regression lines, linear and quadratic, were obtained, and these two regression lines are statistically significant with a probability at more than 99.9%. Following table shows the results of regression analysis. Figure B.6 shows the scatter plot of Paddy Yield of all the samples.

#### Linear Fit

Summary of Fit

Summary or Fit	
R square	0.263138
Root Mean Square Error	1.501187
Mean of Response	5.861151
Observations (or Sum Wgts)	8981

Total-Fertilizer^2	-0.000009615	0	-26.26	0.0000

From above results, paddy yield can be estimated by two formula i.e.

 $Yield = 4.2535352 + 0.005016 \times Total Fertilizer$ 

or

 $Yield = 3.59102 + 0.011124 \times Total Fertilizer - 0.000009615 \times Total Fertilizer^2$ 

Which line is better to estimates the yield from total fertilizer amount?

"F" values of analysis of variance and "t" values of parametre of these two equations show that these two regression lines are estimated to be significant with a probability at 99.99%, and these equations completely fit to the yield increasing pattern by increasing the amount of

fertilizer application. Looking the value of correlation coefficient (R square) which indicates that lager value shows better fitting, curve fitting has rather bigger value than line fitting.

#### 1. Introduction

This technical report of Land Resources Assessment presents physical land potential for wet paddy field development and irrigation development in Indonesia. The results of the analyses offer extension potential of irrigated paddy field to raise rice production capacity in future.

As for land potential assessment, land suitability analysis is carried out primarily for whole land of Indonesia. Then, land availability is analyzed on the basis of present land use and land status. The combination of these results provides further potential of wetland agriculture development from viewpoint of physical land conditions. Generally, land which is suitable for paddy cultivation and available for field extension is considered as potential land for paddy field extension, as explained in the following figure.

#### General Concept of Land Potential Assessment

To assess irrigation development potential, river basin approach from both aspects of water and land potential is adopted. Water availability is another crucial factor that limits extensive irrigation development, but this report does not describe about its analysis in detail (another technical note issue that).

Land resources for wetland cultivation will be assessed in a viewpoint of irrigation development potential in Indonesia. Land potential assessment will couple with water resources potential, because both of them are critical limiting factors of irrigation development.

For assessment of national land potential, Regional Physical Planning Project for Transmigration (RePPProT) study by Ministry of Transmigration is considered to provide the most relevant and fundamental data. This is the only nationwide land evaluation by an integrated land unit approach, not only soil type, in Indonesia. In the RePPProT study, 414 Land Systems are defined in whole national area, then those qualities are evaluated with the requirement of the planned crop or land use type. Following to the land suitability assessment, land availability to be developed is secondly assessed by present land use and land status. Finally, the RePPProT study defines 760 Recommended Development Areas for transmigration by settlement type.

The land resources assessment starts from review of the RePPProT results by the above reason. The classification criteria on the Land Systems and the evaluation criteria on land suitability are re-examined in terms of paddy cultivation with irrigation. Through the process, the land potential of land development is evaluated by integrated criteria consisted of topography, geology, soils, climate, hydrology and so on. At the next step, the potential areas are examined upon another limiting factor of irrigation water availability in each river basin area. The assessment process is to clarify physical potential area of irrigation development in the country.

A similar study of land resources assessment was carried out by Delft Hydraulics/Euroconsult (Project BTA-155). The study also used RePPProT land assessment data, and distinguished land development potential area in the whole Indonesia. The FIDP study carries out the analyses of land development potential in more detail. Further, the FIDP study analyses nationwide irrigation development potential.

#### 2. General Descriptions of Land Resources

### 2.1 Outline of the Integrated Land Unit Approach

The land resources assessment of the FIDP study is carried out on the basis of land system evaluation data by Regional Physical Planning Program for Transmigration (RePPProT) study, because there are not any other systematic maps or descriptions of land characters of

the whole Indonesia. The RePPProT study applied the integrated land unit approach to evaluate land potential for transmigration. This method is more efficient to evaluate the environment in terms of a whole range of attributes, including landform, soils, land cover and climate. Land evaluation then becomes essentially a process of matching the characteristics of the land units defined during the land resources survey with the requirements of defined kinds of land use.

The integrated land unit approach of the RePPProT requires many kinds and large amounts of information concerning to nationwide land resources. Initially airphotographies, satellite imageries and also existing many kinds of topographic maps are collected for physiographic, geographic and vegetation information in the whole Indonesia. For climate and hydrology, long term records at a lot of rainfall measuring stations and river discharge gauging station are applied. For soil characteristics, applicable soil data are collected mainly at Research Center of Soil and Agroclimate, under Ministry of Agriculture. Forestry and environmental issues are also considered using existing forest categories, authorized by Ministry of Forest. Those all data are organized well as examination factors of the national land resources in textbooks and maps, with following processes.

The RePPProT study completed land resources assessment of the eight major regions of Indonesia during 1984 to 1989, and prepared Regional Reviews and three kinds of maps at 1:250,000. Those reports and maps offer a number of data and descriptions about land resources by region.

#### 8 Regional Reviews

(Sumatera, 1988; Jawa and Bali, 1989; Kalimantan Barat, 1987; Kalimantan Tengah, 1985; Kalimantan Timur and Selatan, 1987; Sulawesi, 1988; Maluku and Nusa Tenggara, 1989; Irian Jaya, 1986)

- 237 Land System Maps at 1:250,000
  - (414 land systems with lithology, topography, climate, hydrology, soil and vegetation)
- 237 Present Land Use Maps at 1:250,000 (76 categories of forest and land use types)
- 213 Land Status Maps at 1:250,000
   (Existing and firmly planned developments; gazetted, proposed nature reserves)

The great heap of data and findings about land resources is concluded in National Overview and Atlas in 1990.

- National Overview, 1990
- Atlas at 1:2,500,000

(1. Geology; 2. Mineral and energy resources; 3. Rainfall; 4. Agro-climate; 5. Groundwater; 6. Physiographic type; 7. Land unit and land use planning; 8. Soil; 9. Land cover; 10. Land use/forest; 11. Environmental hazards; 12. Transmigration site/Replita IV; 13. Population distribution; 14. Regional development)

The methodology and original data sources of RePPProT integrated land unit approach are briefly summarized in the following table.

Item	Methodology/Source
Approach	Integrated Land Unit Approach FAO, (1981) The Land Unit Approach to Land Resources Surveys for Land Use Planning, with Particular Reference to the Sekampung watershed, Lampung Province, Sumatra, Indonesia.
Identification unit of Land Systems	Average: more than 400,000 ha.  Minimum: about 50 ha, based on 1/250,000 maps.
Number of Land Systems	414 Land Systems in Indonesia
Land System areas	Measured on 1/250,000 maps and summarized by map sheet and province.
Land Suitability Criteria	FAO (1976) Framework for land evaluation A standard set of principles and concepts on land evaluation system.
Geology	Existing maps at 1/100,000 - 1/1,000,000 by Geological Research and Development Center (up to 1984).  RePPProT photogeological land system maps at 1/1,000,000.  Other survey results.
Climate	Climatic records by Agency for Meteorology and Geophysics.
Hydrology	River gauging and hydrological records by Center for Research and Development of Water Resources.
Physiography	Airphotography (Jawa & Bali, much of Sulawesi and Kalimantan, 1981-82; most of the rest, 1976-79; significant part of West Kalimantan, 1969) for basic information; Recent Landsat, SPOT and radar imagery to fill in gaps.
Soils (Source/ Classification)	Landforms on imagery. USDA Soil Taxonomy (1985) One of world standard soil classification system.
Land Cover (Land Use)	Airphotography (Jawa & Bali, much of Sulawesi and Kalimantan, 1981-82; most of the rest, 1976-79; significant part of West Kalimantan, 1969) for basic information; Recent Landsat, SPOT and radar imagery to fill in gaps and to update forest boundary.
Forest Category	Consensus Forest Land Use Plan (Tata Guna Hutan Kesepakatan, TGHK) in 1982. The areas of categories were revised on the RePPProT maps.
Swamp (Inland)	Adopted by suitability criteria for <u>wetland arable</u> .  Total area and suitability can be identified by Land System descriptions, but availability can not be identified.
Swamp (Tidal)	Adopted by suitability criteria for <u>tidal irrigation</u> .  Total area and suitability can be identified by Land System descriptions, but availability can not be identified.

There is a similar study of land resources assessment as a part of the project BTA-155 (Technical note 3, 1991). The BTA-155 also assessed nationwide land potential for wetland agriculture development. As the FIDP study started after the study, some modifications of methods and further irrigation development potentials could be made by the FIDP. Differences between the FIDP study and the BTA-155 are summarized as follows:

#### Comparison with FIDP Study and BTA-155 Study

Item	FIDP	BTA-155		
General				
Objectives	Land resources assessment for Wetland Development and Irrigation Development	Land resources assessment for Wetland Development		
Data source	RePPProT	RePPProT		
Land suitability				
Land suitability criteria	Unified criteria as described on RePPProT National Overview	Slight modification on RePPProT Regional Reviews		
Land suitability class	4 classes; fully suitable, conditionally suitable, marginally suitable, unsuitable	3 classes; fully suitable, conditionally suitable, unsuitable		
Land Availability				
Present land use and land status	Based on RePPProT Regional Reviews; estimation of each land use area in all land systems	Based on RePPProT Regional Reviews		
Forest criteria	Revised TGHK by RePPProT Regional Reviews; estimation of each TGHK area in all land systems	Revised TGHK by RePPProT Regional Reviews; concerned as forest convertability for only selected suitable area		
Facet reduction factor	Not concerned; unsuitable facets should be removed by identification efficiency index	Unsuitable facets are excluded by facet reduction factor; derived from the descriptions in Regional Reviews		
Identification efficiency index	0.36; from RePPProT Regional Review of Central Kalimantan	0.36; from RePPProT Regional Review of Central Kalimantan		
Land Potential				
Wetland development	Assessed by province and by river basin	Assessed by province		
Irrigation development	Assessed by combined with irrigation water availability by river basins	No assessment		

## 2.2 Agroclimatic Zones

Climatic conditions, such as rainfall, temperature and sunshine, vary significantly in Indonesia. This variation affects moisture regime in relationship soils and plants. These different soil moisture regimes create distinctive soil types, which help to define land systems. Moisture regime also determines the types of plants that can survive in an area under natural conditions, and to hence the area's agricultural potential. USDA Soil Taxonomy Manual, a systematic treatment of soil moisture is applied to define geographic limits for the resulting agro-climatic zones.

Monthly rainfall conditions determine four agroclimatic zones; aridic, ustic, udic and perhumid, and also temperature conditions affected by altitude divide these zones into two groups. The brief descriptions of them and some recommendations for development plans are

#### Aridic or permanently dry zone:

The severest limitations to plant growth are imposed by the climatic conditions of a semi-permanent dry season which create the aridic soil type; this is designated the aridic or permanently dry zone, and is defined as having nine or more months with an average rainfall of less than 100 mm. It occupies 0.34 million ha or 0.2 % of Indonesia, and occurs on the coasts of north and northwest Timor, northeast and southeast Sumba the Palu area of Sulawesi Tengah and smaller coastal patches of east and northwest Wetar, north Lomblen, north Flores and east Sumbawa.

#### Ustic or seasonally dry zone:

Less severe but still difficult conditions are found in the ustic or seasonally dry zone, defined as having five to eight months with an average rainfall of less than 100 mm. It occupies 14.3 million ha or 7.5% of the country, and covers much of the north and east coast and the Solo and Brantas river basins of Jawa, a large area of southeast Irian Jaya, and substantial areas of north and south Bali, northeast Lombok, Sumbawa, Sumba, Flores, Adonara, Pantar, Alor, Wetar, north and west Timor and west Yamdena. It also covers small areas of north Ambon, coastal Sulawesi Tenggara and Sulawesi Selatan, and the Palu valley and Balantak Peninsula of Sulawesi Tengah.

#### Udic or seasonally wet zone:

Most of Indonesia lies within the udic or seasonally dry zone, defined as having up to four months with an average rainfall of less than 100 mm. This zone occupies

134.0 million ha or 70.1 % of Indonesia. It covers most of Sumatera, Kalimantan and Maluku; about half of Jawa, Sulawesi, Timor and Irian Jaya; and small parts of the other islands. Rainfall agriculture is possible in much of this zone, but yields are higher and multiple cropping is possible where the effort has been made to provide supplementary irrigation water.

#### Perhumid or permanently wet zone:

Perhumid or permanently wet zone is defined as having 12 wet months (mean monthly rainfall exceeding 200 mm), and covers 20.6 million ha or 10.8 % of Indonesia. The zone includes extensive areas of the central mountains and bird's head of Irian Jaya, the inland mountains of Kalimantan, small areas of Balisan Mountains and central west coast of Sumatera, two small areas in the mountains of Jawa Barat and Jawa Tengah. This zone is particularly suitable for such trees as oil palm and sago, but is too wet for most other crops.

#### Highland or permanently cool zone:

This cool zone is defined in terms of altitude and includes all land above the 1,000 m contour. It therefore overlaps with wet, moist and dry zones (though not with the aridic zone) to give sub-zones with distinctive combinations of characteristics. These cover 21.9 million ha or 11.5% of the country. Highland agriculture as practiced in most areas involves such crops as maize, wheat, sorghum, soybean, groundnut, banana, arabica coffee and a range of temperate latitude vegetables and market garden produce particularly near the major cities of Jawa and Sumatera. This form of agriculture is found in the submontane subzone, between 1,000 and 2,000 m.

The agroclimatic zones recognized by the RePPProT consists of aridic, ustic, udic, perhumid and highland units, respectively termed the permanently dry, seasonally dry, seasonally wet, permanently wet and permanently cool or highland zones. Within the cool/highland zone, sub-montane and montane and alpine sub-zones are recognizable. The areas of Indonesia found in the respective zones are give in following table.

Areas of Agroclimatic Zones by Region

(million ha)

Region	· .	Hot				Cool		
	Wet	Moist	Dry	Arid	Wet	Moist	Dry	
Sumatera	0.82	41.70	0.16	0.00	0.21	4.64	0.00	
Jawa & Bali	0.10	6.10	5.27	0.00	0.09	2.02	0.24

### 2.3 Physiography

The major physiographic types in Indonesia shown on Atlas Map 6 are a selection of specific and general landforms, chosen mainly for their importance for land planning considerations. Thus, the lowland types are quite detailed while the hills and mountains are not differentiated. The map at a scale 1:2,500,000 has been simplified from land system map series at 1:250,000. Brief descriptions of the 414 land systems are grouped by physiographic types, and the legend to the land system maps in the Regional Reviews is similarly subdivided.

The distribution of these more useful physiographic types within the country is not uniform. The following table shows the distribution of physiographic types by Regional Review area. When grouped into physiographic types each land system can occur in one category only. In the second grouping of land systems into physiographic regions a land system may be found in several categories.

Physiographic Types by Region

(million ha)

Physiography	Sumatera	Jawa/Bali	Kalimantan	Sulawesi	Maluku/NT	Irian Jaya	Total
Beach	0.42	0.10	0.14	0.16	0.19	0.20	1.21
Tidal swamp	0.86	0.17	1.09	0.22	0.24	1.43	4.01
Peat swamp, marsh	6.21	0.00	5.11	0.22	0.00	5.36	16.90
Meander belt	0.83	0.00	0.00	0.07	0.10	0.60	2.08
Seasonal swamp	0.00	0.00	2.57	0.00	0.00	2.11	2.11
Alluvial plain	4.28	1.83	0.41	1.00	0.67	1.18	11.53
Alluvial valley	0.40	0.18	0.00	0.13	0.15	1.76	3.02
Alluvial fan, lahar	0.77	1.01	3.23	0.76	0.37	0.79	3.70
Тептасея	1.46	0.47	18.88	0.03	1.03	1.72	7.95
Plain (non-alluvial)	16.00	5.77	7.92	2.14	2.31	6.84	51.86
Hill	4.85	1.95	13.35	2.51	3.53	2.76	23.52
Mountain	10.18	2.19	0.50	11.20	7.17	16.41	60.50

The physiographic types may be divided into two broad groups for planning purpose; those with potential for a wide range of agricultural development activities and those with no potential or a limited potential for a much narrower range of developments. The beaches, all three types of swamps, most of terraces and hills, and the mountain physiographic types all have very limited development potential. The tidal swamps have potential only for brackish water fisheries development and the beaches, terraces, hills and mountains have potential only for a limited range of tree-crop and forest plantation developments. Many of these areas have greater significance for mining, tourism or conservation, for example, than for agriculture.

The physiographic types with potential for a wide range of development activities are the alluvial plains, meander belts, alluvial valleys, fans and lahars, and a wide range of non-alluvial plains. With varying levels of inputs, wetland rice cultivation, dryland arable farming and a wide range of tree-crop developments are all possible in these physiographic types. Overall, about 38 % or 722,000 km² of Indonesia consists of the physiographic types with potential for a wide range of development activities, although peat swamps and marshes with an area of 8.9 % are considered to be suitable for wetland rice cultivation using low-input technology. The Jawa and Bali region has the greatest proportion of better quality land (64 % or 8.8 million ha), and Sulawesi (22 % or 4.1 million ha), Maluku and Nusa Tenggara (23 % or 3.6 million ha) and Irian Jaya (27 % or 11.2 million ha) the smallest.

#### 2.4 Soils

The soil identification in Indonesia is carried out in the RePPProT Regional Reviews, in line with USDA Soil Taxonomy (1985) methods and criteria. The recognized eight soil Orders in Indonesia are Histosols, Entisols, Inceptisols, Aridisols, Mollisols, Vertisols, Alfisols, Utisols, Spodosols and Oxisols. The major 34 soil Great Groups within the Orders are identified and mapped, as listed in the following table. General features and distributions of the Great Groups are explained in Table 2.1.

Major Soil Orders, Suborders and Great Groups in Indonesia

Order	Suborder	Great Group	
Histosols	Hemists	Tropohemists	
Entisols	Aquents Orthents Psamments Fluvents	Tropaquents, Fluvauents, Hydraquents Troporthents, Ustorthents Tropopsamments, Ustipsamments Tropofluvents, Ustifluvents	
Inceptisols	Aquepts Andepts Tropepts	Tropaquepts Dystrandepts, Eutrandepts, Vitrandepts Dystropepts, Eutropepts, Ustropepts, Humitropepts	
Mollisols	Ustolls Rendosols	Calciustolls	
Vertisols	Usterts	Pellusterts	
Aridisols	Orthids	Calciorthids	
Alfisols	Udalfs Ustalfs	Tropudalfs, Paleudalfs Rhodustalfs, Haplustalfs	
Ultisols	Udults Ustalfs	Paleudults, Tropudults Rhodustalfs, Haplustalfs	
Spododols	Aquods	Placaquods, Tropaquods	
Oxisols	Orthox Ustox	Haplorthox Haplustox

Indonesian soils range from highly fertile to virtually sterile, with a wide range of intermediate condition. Those which have least limitations for non-irrigated cultivation and which are already used intensively are deep, well drained soils of moderately fine texture and with as well balanced nutrient status. Such soils occur on young intermediate or basaltic volcanic of the volcanic arc as Eutrandepts, Eutropepts or Ustropepts. On calcareous parent materials of the outer arc and in parts of Kalimantan and Irian Jaya, Alfisols, Vertisols, Hapludosols and Haplustolls also fulfill these conditions but have a more restricted distribution. Young reverine and estuarine plains on all the major islands also support intensive irrigated agriculture on poorly drained but relatively fertile Tropauepts.

The most difficult soils to deal with are the very strongly weathered and leached, waterlogged Placaquods and sterile Quartzipsamments of Kalimantan and east Sumatera quartz-sand terraces, the deep peats of Sumatera and Kalimantan and Irian Jaya, the toxic Haplorthox on ultrabasic rocks of Sulawesi, Maluku and Nusa Tenggara, and the shallow Troporthents, Rendolls and Calciustolls of limestone karst and mountains. Together, these
