2. Construction Plan and Construction Cost

2.1 Construction Schedule

2.1.1 General

The construction schedule of Xe Katam Project is such as detailed in Chapter III, Section 4. That is, the plant output of 2,000 kW to be constructed in the First Stage will be commissioned by 1995, and then the plant output will be increased to 6,000 kW at the completion of the Project.

The construction work of the First Stage will be started by the beginning March of 1994. The construction schedule of the First Stage is planned as presented in Fig. IV-2-1, so that the power generation will be started by the beginning of August, 1995, or in 17 months.

It is required to conduct the basic design survey, develop the detailed design, and produce specifications, and then complete the procedures of bidding and award of contract before the construction work is started. We assumed that 2 years of period from 1992 to 1993 will be required to the above works.

Concerning the timing of commissioning of 4,000 kW output of the Latter Stage, there are various points of view, but the plant output of 2,000 kW will be constructed to divide into two to meet Sekong and Attapeu needs of electricity. In this study, it was tentatively assumed that first 2,000 kW output will be commissioned by the beginning of October of 2001, later 2,000 kW output will be commissioned by the beginning of October to 2011, with the construction period being 17 months and 16 months, as illustrated in Fig. IV-2-2 and Fig. IV-2-3. Any construction works will be carryout centering around in the dry seasons.

2.1.2 Construction Works to be Implemented in Each Fiscal Year

(1) First Stage of Project

a) Starting Year (1994)

As soon as the construction work is started at the beginning of March, 1994, the transportation of the construction materials and equipment to the site will be started (for the transportation route, refer to Paragraph 2.2.1). As the construction materials and equipments arrive at the local depot, the existing road from Ban Houaykong to the construction site will be expanded in width and repaired, and bridges will be constructed rapidly. Then, as soon as the working systems at the construction site are prepared, the construction works for electric power supply, concrete production facility, excavation facility, provisional buildings and other provisional facilities will be started. The construction work of the new roads as described in the preceding close (1.10) will be started before the rainy season and will be nearly completed. As the road leading to the power plant is as long as 2,600 km, and runs along steep mountain slopes, the construction work of this road, together with the construction work of the power plant, are the critical paths in this Project. Therefore, the construction work of the road will be continued throughout the rainy season, and the road will be completed by the end of October when the next dry season starts (with the construction period being about 8 months).

As soon as the approach road to the sediment discharge tunnel portal is completed, the excavation facilities of the headrace tunnel will be installed in the portal, and the sediment discharge tunnel and headrace tunnel will be excavated. The excavation will be completed within that year, and some part of concrete lining will be completed.

Excavation works to be performed on the ground, including those of intake dam, intake, sand stilling basin, culvert, penstock,

and power station will be performed as soon as the dry season arrives, and some concrete placing works will be performed within that year.

The design and manufacture of the FRP pipes, steel pipes, manifolds, etc. of the penstock will be started at the same time with the main construction work, and these components will be transported to the construction site within that year.

The design and manufacture of the hydraulic turbine and the generator will be started at the same time with the main construction work, and the transportation of these equipments will be started within that year.

The procurement of materials of the transmission line will be started at the same time with the start of the main construction work. The transmission line components will be transported to the site within that year, and the construction work of the transmission line will be started.

b) Completing Year (1995)

The concrete placement for the intake dam, intake, sand stilling basin, culvert, headrace tunnel, penstock and power station will be continued from the preceding year, and the work will be completed by April or May.

The installation of FRP pipes, steel pipes, manifolds, etc. of the penstock will be conducted in parallel with the concrete placement of foundation, and works will be completed by May.

The construction work of the power station building will be started, and completed by May.

The installation work of the hydraulic turbine and the generator will be started as soon as they are transported to the site. The 2,000 kW generating unit will be completed in June. The test operation will be conducted in July, and the power transmission will be started by the beginning of August.

The construction work of the transmission line will be continued from the preceding year, and the line will be completed by the time when the generating unit starts power transmission.

(2) Latter Stage (First) of Project

a) Starting Year (year 2000)

In May, 2000, as soon as the construction work of the Latter Stage is started, the transportation of construction materials and equipments to the site will be started. The provisional facilities will be constructed as soon as materials and equipments arrive, which will be completed by the end of the rainy season. The excavation work for the penstock and the power station will be started as soon as the dry season is entered, and will be practically completed by the end of the year.

The design and manufacture of FRP pipes, steel pipes and manifolds will be started at the time of the start of construction work, and will be completed within that year. The design and manufacture of the hydraulic turbine and the generator will also be started.

b) Completing Year (2001)

The concrete placement for the penstock and the power station foundation will be started by the end of the preceding year. A part of concrete of the power station foundation will be placed at the time when the hydraulic turbine generator is installed.

The installation of FRP pipes, steel pies and manifolds will be conducted in parallel with concrete placement of the foundations, and will be completed before the rainy season comes (in May). The construction work of the power stations building will be started as soon as the foundation is set, and the building will be completed before the rainy season comes (in May)

The manufacture of the hydraulic-turbine and the generator will be completed by January, and it will be transported to the site by March or April. The installation will be worked out as soon as it is transported. The generating unit will be subjected to test operation in September, and power transmission of 2,000 kW will be started by the beginning of October.

(3) Latter Stage (Second) of Project

The construction work of the Latter Stage (Second) will be design, manufacture and installation of the only hydraulic turbine and the generator.

The construction period being 16 months as presented in Fig. IV-2-3. The design and manufacture of the hydraulic turbine and the generator will be started at the time of the start of construction work (by the beginning June of 2010), and will be completed by the January of 2011.

The installation work of the hydraulic turbine and the generator will be started as soon as they are transported to the site by March or April.

The generating unit will be subjected to test operation in September, and power transmission of 2,000 kW will be started by the beginning of October.

2.2 Construction Plan

2.2.1 Location of Project and Transportation Route

(1) Location of Project

The Xe Katam Project is located in Attapeu Province, which is one of southern provinces of the Lao People's Democratic Republic, at a location 106°38' longitude east and 15°07' latitude north. This location is approximately 100 km to the east of Pakse City which is the capital city of Champasak Province, approximately 50 km to the east of Paksong city, approximately 25 km to the southwest of Sekong City which is the capital city of Sekong Province, and approximately 40 km northto-north west to Attapeu city.

The location of this Project is at the most downstream site of the Xe Katam River, which is a small tributary flowing into the Xe Nomnoy River, which is against a tributary of the Xe Kong River of the Mekong River System. This Xe Katam River flows to the southeast along the foot of a mountain range located in the northeastern part of Bolaven Plateau, and joins the Xe Namnoy River. The Project Site is located at an elevation between 300 m to 500 m.

(2) Transportation Route

The normal way of transporting personnel, machinery and material to the Project Site is along the route which passes through Vientiane. The trip distance from Vientiane to Pakse is around 800 km by land, or 1.5 hours by air.

The construction machines and other materials required for this construction work are as presented in Table IV-2-1. It is being planned to transport these items to Pakse from Bangkok via Chong Mek in the Thailand side of the border, which is the route specified as described in the basic condition of cost estimation clause 2.3.2 (Figure IV-2-4).

The marine transportation from Japan to Thailand will take approximately 1 month, including the time required for custom clearance and other procedures.

The road distance for the inland transportation from Bangkok to Chong Mek on the boarder by inland is approximately 750 km, and heavy items can be transported by this road. The span of approximately 35 km from Chong Mek to the Mekong river is completely paved, and there are 7 bridges in this section of the road. The features of these bridges are presented below.

(From Chong Mek)	Width (of Traffic Lane) (m)	Height of Handrail from Traffic Surface (m)	Design Weight (t)
No. 1	4.0	1.1	40
No. 2	3.2	0	40
No. 3	2.9	0	40
No. 4	3.8	0.8	40
No. 5	4.3	1.1	40
No. 6	4.4	1.1	40
No. 7	3.25	1.7	20 (possibly 30)

Heavy articles can be transported by this route.

The transportation capacity (3 lorries) of the ferry boat on the Mekong River has been verified by the transportation of heavy equipment in the Xe Set Project, and the transportation of heavy items for this Project across the river is possible.

National Route 23 from Pakse to Paksong is approximately 40 km long. The section of 30 km nearer to Pakse is provided with simplified asphalt pavement, but the remaining 10 km nearer to Paksong is paved by gravel, and this section has considerable undulation. There is one bridge on this road (4 m width, 27 m length, double main girder Beiley steel bridge), which can support traffic of heavy items. Laos plans to improve this section by 1994.

The section of approximately 30 km from Paksong to Ban Houaykong (which is a village nearest to the Project Site; 16 km away) is an unpaved road, which is 4 to 8 m in width having poor road surface. In a rainy season, it is impossible for vehicles except trucks to pass this section of the road. Heavy materials can be transported in dry seasons, although the road surface has undulation. There is one bridge in this section of the road (a 4 m width, 24 m length, one main girder Beliley steel bridge), which can not carry heavy items. The heavy items will be directly transported across the river water at this section. To perform this, the river banks must be modified. Laos plans to implement this improvement in 1994 to 1996.

An approximately 16 km section from Ban Houaykong to the Project Site is an unpaved road having 4 to 5 m width, on which small four wheel drive cars can drive. In this section, five wooden bridges (9 m, 23 m, 7 m, 18 m and 5 m), and a ford (river crossing without bridge, with river width of 38 m) are used. These places must be repaired or provided with bridges in an early period of the main construction work. The repair and bridge building costs for these sections are included in the Project Cost.

The approximately 70 km section of National Route 16 from Sekong to Attapeu is being its road width expanded since 1990, and this improvement work is scheduled to be completed by 1994. From this Route 16 to the Project Site, only a path traveled by men exists today (for approximate distance of 17 km). This section is included in the road improvement plan (from 1994 to 1996) of Laos.

2.2.2 Provisional Facilities for Construction Work

(1) Construction Road

The completion of the transportation road controls the schedule of the construction work of this Project. In particular, the 16 km section

from Ban Houaykong to the Project Site, which may pose problems on the feasibility of transporting the construction materials/equipments, must be improved and provided with temporary bridges. The improved road must be 4 m in width and provided with gravel road, and the temporary bridges must have H-form steel main girder covered with steel plate, and equipped with side railing. For the First Stage of Project, the roads will be repaired and maintained for the purpose of securing easy transportation. In the Latter Stage, roads must be fundamentally repaired and improved.

(2) Electric Power for Construction Work

For the First Stage construction work, a diesel generator set of 250 kVA capacity and two sets of 75 kVA capacity, which one is used in night and another is used in spare, as well as associated substation facility, will be installed at the construction site. Electric power will be supplied to switchboards located at relevant locations (aggregate plant, dam, tunnel, penstock and power station) by high voltage distribution line, and then from switchboards to loads by low voltage lines. In the Latter Stage, the power required for the construction work will be supplied by the power plant already completed.

(3) Concrete Facilities

The each total amount of concrete used and gravel road used will be approximately 6,500 m³ and 7,000 m³ for the First Stage, and approximately 1,300 m³ and 1,000 m³ for the Latter Stage. The total amount of aggregate will be approximately 17,000 m³ for the First Stage, and approximately 3,000 m³ for the Latter Stage. As there is no concrete plant near the Site, and aggregate plant and a concrete plant will be installed on the construction work ground on Xe Katam Plateau.

For the gravel and sand used for concrete, the muck from tunnel excavation, open cut excavation, the stones on the river bed to the upstream of intake dam, the stone hill on the right bank, and stones collected from the center shoal of Xe Namnoy river will be collected and crushed to secure the aggregates. The capacity of each plant will be determined based on the concrete placing schedule, and they will be $18 \text{ m}^3/\text{h}$ and 20 ton/h classes for the First Stage construction work, and $10 \text{ m}^3/\text{h}$ and 10 tons/h for the Latter Stage.

The concrete placement will be performed basically by fixed concrete pumps, but chute placing shall also be employed.

(4) Excavation Facilities

a) Air Supply Facility

The compressed air required for the construction work will be supplied from a stationary compressor stations, which will be located at three points, the dam, the tunnel and the power station in the First Stage. In the Latter Stage, one compressor station will be provided at the power station. The air will be supplied by piping from the stations to the loads.

b) Water Supply Facility

In the First Stage, the water supply will be secured by the Xe Katam River and the Xe namnoy River, and water storage tanks will be provided at three locations, the dam, the tunnel and the power station. Water supply pipes will be provided from each water storage tank to the places of work.

In Latter Stage, the Xe namnoy River will be used as water supply source, and a water storage tank will be provided at the power station. The water will be supplied from the tank to the penstock by providing piping.

c) Drainage Facility

In First Stage, drain pumps and drain piping will be provided at the quarry site, the dam site, the tunnel and the power station to facilitate the construction work. In Latter Stage, drainage facilities will be provided at the power station.

d) Ventilation Facility

To assure the safety of construction work inside tunnels, propeller fans will be installed at the portal and inside of tunnels, and they will be connected (inside tunnels) by air ducts.

e) Muck Discharge Facility

The mucks generated in tunnels will be discharged to outside by rail system (15 kg rails), and the necessary tracks will be installed inside tunnels.

f) Care of Rivers

For temporary closing of the river, only one half of the river will be closed off alternately by embanking sandbags to divert river water and perform dry works. First, the approximately 50 m length of the right bank, where the intake and sand flush gate are to be constructed, will be closed off in a dry season, to complete the sand flush gate and intake. The river water is let to flow the left bank side during this construction work. When they are completed, the approximately 30 m length on the left bank of the river will be temporarily closed off to let the river water flow switched to the sand flush gate, and remaining part of the intake dam on the left bank will be completed.

During the construction work of the power station, sandbags will be embanked along the left bank of the Xe Namnoy River near the power station for a length of approximately 40 m, to prevent overflow of the river water.

(5) Temporary Building Facilities

The temporary building facilities required for the First Stage and Latter Stage (administration building, supervisor's dormitory, labor camp, and ancillary facilities such as warehouse and repair shop) will be built near the central approach road located at the central part of Xe katam Plateau.

(6) Other Facilities

Communication facilities and cable facilities are required in the First Stage, and cable facilities will be required in the Latter Stage.

Communication equipment capable of providing communication between Vientiane, Pakse and Ban Houaykong will be installed.

The cable facilities will include the 2-ton rating cable crane to be provided to the span of approximately 300 m for the whole length of the penstock, and an incline equipment.

As for other items, the illumination facility inside tunnels will consist of 100 W incandescent lamps located with 2.5 m intervals (plus 20 W emergency lights located with 20 m intervals), and the cutting face will be equipped with several projector lamps of no less than 100 W rating to assure safety.

2.2.3 Construction Method of Each Structure

(1) Intake Dam

The care of river flow is closed off by the half-close off method. As there is no soil or sedimentation on the river bed of the dam site and the rock is exposed, the excavation will be performed by drilling with a 30-kg class leg hammer and by blasting, and then scraped with a 15ton class bulldozer equipped with ripper. A large breaker will also be employed for supporting excavation. The hard rocks excavated will be transported to the aggregate plant, and other mucks will be transported by 11-ton dump trucks to be disposed of at "A" disposal area.

After excavation is completed, concrete placement will be performed without foundation treatment. Concrete will be transported from the concrete plant by 3 to 3.2 m^3 class truck mixer, and will be placed by employing chute or pump appropriately. Placement will be 15 m per block, and each lift will be 2 to 3 m as in standard.

The lower part structure of the sand flush gate will be completed before the care of river is switched from the right bank to the left bank. The true form of the sand flush gate will be installed after the care of river is switched and structure will be completed.

(2) Intake

The excavation will be performed by the ripper cutting employing explosive (leg hammer)method, similarly to the excavation of the intake dam. The hard rocks excavated will be transported to the aggregate plant, and other muck will be transported by 11-ton dump trucks to be disposed of at "A" disposal area.

The concrete placement will also be performed similarly to the intake dam, and the concrete transported from the concrete plant by truck mixer will be placed by employing pump and chute.

As the intake will be constructed right upstream to the sand flush gate, making right angle with the dam and near the right bank, it is hoped that all construction works including the installation of water control gate will completed before the care of river is switched from the right bank to the left bank, but it is available after the care of river.

(3) Sand Stilling Basin and Culvert

The excavation and loading of the surface soil is performed by 0.6 m³ back hoe, and all excavated soil is transported by 11-ton class dump trucks to "A" disposal area. The cutting of rocks is performed by ripper excavation employing explosive (leg hammer) similarly to the cases of intake dam and intake. The hard rocks excavated will be transported to the aggregate plant, and other mucks will be transported by 11-ton dump trucks to be disposed of at "A" disposal area except those used for embankment and backfill.

When excavation is completed, reinforcing bars are assembled and concrete is placed. The concrete placement will be performed similarly to the case of intake.

After the concrete structures of sand stilling basing and culvert are completed, the backfill is performed by 0.6 m^3 class back hoes, and the embankment by back hoes, bulldozers and tampers.

(4) Headrace Tunnel and Sediment Discharge Tunnel

a) Excavation

The tunnels will be excavated by the full face excavation method employing blasting, and the sand flush tunnel will used as the construction tunnel. The excavation will proceed from the portal toward upstream direction.

In locations where the rock conditions are poor, timbering of steel arches made of H-form steels (H - 100 x 100 x 6 x 8) will be installed with standard interval of 1.5 m.

The drilling will be performed by employing simplified scaffolds and wet type leg hammer, and pit hammers will be used to remove loose stones and projections. Removal of mucks will be performed by a rial system consisting of a 0.2 m^3 class muck loading machine, a 4-ton battery locomotive, and two steel carts, which travels back and forth to carry mucks to the outside of the tunnel (refer to Fig. IV-2-5). Hard rocks contained in the mucks thereby recovered will be transported to the aggregate plant, and other portions to the "A" disposal area by 11-ton class dump trucks.

b) Lining Concrete

As the cross section of the tunnel is small, the lining concrete will be placed after all excavation is completed. Starting from the final excavation face to the tunnel portal, the arch sector will be placed by means of a sliding form, and the invert sector will be worked after the arch is completed. The concrete for lining will be transported by truck mixers from the concrete plant to the tunnel portal, where it is directly transferred to the concrete placer (2 m³ capacity), which will be transported the inside of the tunnel by a battery locomotive.

c) Injection of Mortar Back-filling and Grouting Work

Injection of mortar backfilling will be made to sufficiently fill up gaps between rear-side of lining and excavated tunnel section, through an injection tube which is to be laid at arch portion.

Grouting work will be performed more than 2 weeks after mortar is injected. The grouting pressure will be 15 kg/cm² at maximum at the injection port. When the injection flow drops below 15 to 20 liters per second with the maximum pressure, injection is stopped while keeping the pressure as it is. The standard mix is 6:1 to 1:1 in the ratio of water to cement. Grouting work may be replaced by mortar injection depending on the geological condition.

IV-2-15

(5) Penstock

In construction works of both First Stage and Latter Stage, the excavation of steep slope at the upstream part will be performed by means of human power and small sized back hoe, from upstream side toward downstream side. For the part having gentle slope at the downstream, the soils will be excavated by 0.6 m^3 class back hoe, and rocks will be excavated by combination of a 0.6 m^3 class back hoe and a large breaker. The excavated soils, except those used for back-fill, will be transported to "B" disposal area by 11-ton class dump trucks.

After the excavation work is completed, the concrete of anchor blocks and the continuous foundation will be placed. In placing concrete at the upstream part, a combination of pump placement, chute placement and bucket placement employing cable crane will be used. For the downstream part, the concrete transported from the concrete plant by truck mixers will be placed by combined use of pump and chute.

The installation work of penstock is divided into four different operations; the installation into the lining of headrace tunnel end, installation at the steep slope of upstream section, installation at the gentle slope of downstream section, and installation of the penstock end to the power plant.

- a) To install the penstock to the headrace tunnel end lining, rails will be installed after the concrete lining is completed, and the penstock section is lifted from the penstock construction road to a cart by means of a cable crane, and it is moved to the specified position by human power. The cart is equipped with jacks to adjust the penstock position. After the penstock is properly positioned, the filling concrete will be placed by a concrete pump. Installation of penstock to the tunnel lining and the installation of the manifolds above the ground will be completed in the First Stage.
- b) In installing the penstock on the steep slop of the upstream part, the penstock is directly pulled up to the installation

IV-2-16

position from the power station construction road by means of a cable crane. First, the curved pipes (steel pipes) will be installed on each anchor block, and then straight pipes (FRP pipes) will be installed from lower locations toward upper locations. The joint between curved pipes and straight pipes will be connected by sleeve joints, and the straight pipes and straight pipes will be connected by T-joints.

- c) The installation on the gentle slope at downstream part will be performed by pulling up the penstock from the power station construction road by means of cable crane or incline cart, and the method of installation will be the same as the installation at steep, upstream part.
- d) The lower end of the penstock will be installed to the power station by lifting the penstock from the construction road to the specified position by means of 15 to 16 ton crane truck.

(6) Power Station and Tailrace

)

The excavation of power station and tailrace will be performed by 0.6 m^3 class back hoes. The operation will proceed from ground surface to downward with a lift of 2.0 m. The excavated soil will be transported to "B" disposal area by 11-tons class dump trucks.

The concrete placement will be performed from the construction road by combined use of pump placement, chute placement, and bucket placement by track crane, and the foundation concrete for the power station and tailrace will be place first. Then, the power station side walls, slabs, etc. will be constructed in sequence.

The installation of the generator will be performed by first installing the overhead traveling crane, which will be used to install the hydraulic turbine, the generator, etc.

(7) New Roads

The new roads will be newly constructed in 5,530 m total length, 8 m width and 4 m width of the new gravely roads, as described in the preceding Section (Section 1, Preliminary Design). For the construction of this road, the primeval forest will be cleared by bulldozers, then the ground will be leveled by motor graders, on which gravels will be placed for a thickness of 20 cm, and compacted by rollers. The shaping of the side slopes will be performed by mechanized operation employing back-hoes, to complete the road in a short period. Maintenance and repair works will be required for the period of First Stage construction work. The construction road will have to be repaired again for the Latter Stage construction work.

2.3 Construction Cost

2.3.1 Summary of Estimated Construction Cost

The total construction cost (including interest during construction IDC) is $25,775 \ge 10^3$ US\$ (15,679 $\ge 10^3$ US\$ for the 2,000 kV First Stage, and 10,096 $\ge 10^3$ US for the 4,000 kW of the Latter Stage). The breakdown of this total construction cost for each construction item, and the year-wise phasing of expenditure are presented in Table IV-2-2 - IV-2-4.

2.3.2 Basic Conditions of Cost Estimation

The construction cost was obtained by adding up all cost items based on the standard material/labor rates and standard calculation methods prevailing in Japan, and according to the following basic conditions. The calculations were performed by taking into account the unit construction costs of hydroelectric power projects in Laos, such as Xeset, Selaban, etc., as well as the cost data of hydroelectric power plant construction projects of similar scale in Japan and South East Asia, and considering the natural conditions, regional conditions, the scale of construction work and results of site survey, based on the assumption that the project will be consider a special fund allowance. The construction costs are calculated based on a 1991 prices level, and the price escalation in the future is not taken into account.

(1) Exchange Rate

The exchange rates of the local currency of Kip and Thai Bahts to US dollars are assumed to be 1 US\$ = 700 Kip and 1 US\$ = 25.71 Bahts, which are the rates effective in June 1991 when the site survey was conducted. The exchange rate between US dollars and Yen is 1 US\$ = 136 Yen (TTS rate issued by the Bank of Tokyo) which is the average exchange rates from January 1991 to June 1991 (Table IV-2-5).

(2) Escalation

As for the items included in the cost estimates of which prices in 1991 are unknown, the 1991 prices were calculated as described below:

The price escalation in Laos has been determined by referring to the price indices of Xeset (Table IV-2-6). For items to be procured in Japan and Thailand, the prices have been estimated by reference to the trends in the past three years and the recent demand/supply balance.

(3) Procurement of Materials and Equipment

Construction materials will be locally procured in principle, and in case they are not available, they are to be procured in Japan or in third nations (such as Thailand).

According to the above rule, the reinforcing bars, cement, light oil and concrete poles will be procured in Laos, dynamite, detonating fuses, and electric conductors will be procured in Thailand, and all other items will be procured in Japan.

(4) Cost Calculation Method

The method of cost calculation is based on the official standard of Japan, and the prices are estimated based on the data obtained during the site survey (material unit price, labor unit price, etc.).

a) Unit Price

Concerning the prices of items to be locally procured, the following unit prices were used mainly by referring to the official prices specified by the government agencies and also referring to the unit prices in other projects in Laos.

ltem	Unit Pric	ce (US\$)	Place of Procurement
Reinforcing bar	ton	645.0	Laos
Cement	ton	125.0	Laos
Light oil	liter	0.43	Laos
Dynamite	kg	4.7	Thailand
Detonating fuse	piece	0.6	Thailand
Electric conductor	meter	0.03	Thailand
Concrete pole (12 m length)	a pole	150.0	Laos
Concrete pole (8m length)	a pole	50.0	Laos

For items to be procured in Japan, the construction prices in Japan and the prices listed in the standard cost estimation document were used.

The labor unit price of the foreman was quoted from the standard price set by the three Ministries (the Ministry of Construction, the Ministry of Agriculture and Forestry and Fisheries, and the Ministry of Transportation) of Japan for fiscal year 1991. Other labor unit prices were quoted from the unit prices in Laos (Table IV-2-7).

The standard salaries and associated costs of technical personnel to be dispatched from Japan is quoted from standards applicable ODA projects in Japan.

b) Rates

The material rates of civil works were quoted from the efficiency value used in Japan, and the labor rates were calculated by multiplying the rate values in Japan by an incremental coefficient of 3. The working capacity of civil work machines was assumed to be 50% of the working capacity (efficiency) in Japan.

(5) Transportation Plan

All materials and equipment to be imported were assumed to be transported from Japan or Bangkok, and the transportation costs are included in the cost calculation. The transportation route to the construction site of this project is illustrated below.

Japan> Bangkok	> Chong Mek	> Mekong Riv	ver> Pakse>
			Project Site
		(ferry transport	ation)
(marine	(truck	(truck	(truck
transportation)	transportation) [Thailand]	transportation)	transportation)

The operations involved in the transportation depicted above are as presented below, and it will take approximately 3 months for the whole trip.

- * Material/equipment procurement
- * Marine transportation (Japan to Bangkok, including customs clearance, mooring, unloading)
- * Inland transportation (Inside Thailand; from Bangkok to Thailand-Laos border)
- * Thailand-Laos border: customs clearance, loading
- * Inland transportation (Inside Laos; from Thailand-Laos border to Mekong River)
- * Ferry boat transportation (Mekong River)
- * Inland transportation (Mekong River --> Pakse --> Project Site)

It is assumed that any customs duties, levies and tax are not imposed when the supplies pass the Thailand-Laos border.

(6) Total Working Days in a Year

The holidays of Laos are as listed below.

January 1	:	New Year's Day
March 8	:	International Women's Day (for females
		only)
April 14 through 16	:	Laos' New Year's Day
May 1	:	May Day
October (an indefinite day)):	The last day of Buddhists Lent
December 2	:	Independence Day

In addition to the above holidays, local holidays are observed in the area including the Project Site, and work is not done similarly to national holidays.

May (an indefinite day) July (an indefinite day) August (an indefinite day) September (an indefinite day) November (an indefinite day): Tat Alun Temple's Festival Total 5 days As described above, there are 13 holidays which are to be taken into account in cost calculation, and the total number of resting days including holidays is 65 days for year.

The number of work stoppage days during which works are suspended during rain and after rain depends on the soil condition, working conditions, topography and the condition of drainage. In this cost estimation, reference is made to the "Document for Operation/Management of Construction Machines and Cost Calculation" edited by the Construction Price Survey Association, in which the number of work suspension days are defined in relation to soil conditions and amount of precipitation, and defined the working conditions during rainfall and after rainfall as described below.

Daily Precipitation	Working Condition
No rain	All day work
0 - 3 mm	All day work
3 - 10 mm	0.5 days work
10 - 30 mm	l day off
More than 30 mm	2 days off

The number of idle days due to rain is calculated to be 80.5 days by means of precipitation data dealing with the average values from 1980 through 1990 at Nonghin site on the above-mentioned conditions.

The total number of working days throughout the year is calculated to be 219.5 days and the average number of working days per month will result in about 20 days.

The working hours of construction work per day (during day time) as 8 hours have been set up in principle, and the working hours on Saturdays is also 8 hours as in weekdays. The standard of tunnel excavation work has been worked out on assumption that the work is to be performed by two shifts per day (with one shift working 12 hours).

2.3.3 Estimated Construction Cost

(1) Civil Construction Costs

The constitution of civil construction costs as follows (Table IV-2-8).

a) Direct Costs

The direct construction unit cost has been calculated by adding up all unit prices according to the standard rates and calculation standard of Japan, under the basic conditions stipulated in the preceding Paragraph (2.3.2) (Table IV-2-9). The unit costs added up consists of the labor cost, material cost, machinery cost and administration costs, and the depreciation charges of the construction machinery was included in the machinery cost.

The direct construction cost consists of the construction costs of the intake dam, intake, sand stilling basin, culvert, headrace tunnel, sediment discharge tunnel, penstock, powerhouse, tailrace, switchyard, disposal area (A and B), new road and powerhouse building, and each construction cost was calculated by multiplying the work amount (Table IV-2-10) with the added up unit prices discussed above. The standard construction price in Japan was applied to the powerhouse building.

Expenses required for the conservation of the Xe Katam river basin and other expenses which will be described in the Clause IV-5, "Environmental Influences" are mainly included in this clause.

b) Provisional Facility Costs

The provisional facility costs consists of the costs of excavation facilities, concrete facility, transportation facility, electric communication facility, temporary building, depreciation charge of construction machines, transportation of

machines, expenses for common equipment, and cost of safety measures, and the installation cost, removal cost, depreciation and maintenance/repair cost of each facility were added up in the same way as the calculation of the direct construction cost.

i) Excavation Facilities

The excavation facilities consisted of air supply facility, water supply facility, drainage and ventilation facility, tunnel muck discharge facility and the care of river for dam and powerhouse construction.

ii) Concrete Facility

The concrete facility included in the calculation of the temporary facility cost was the concrete placement facility (including forms) only. Other facilities, such as aggregate plant, concrete plant, water supply facility, mortar injection facility and grouting facility were calculated in terms of corresponding construction unit price of the direct construction cost.

iii) Transportation Facilities

The transportation facilities consist of the repair of the construction road (the 16 km section from the Site to Ban Houaykong), temporary bridge construction, maintenance and repair cost of the new roads and cable way facilities.

iv) Electrical Communications Facilities

The electrical communications facilities consist of the power generation facility, transformer, switchboards, distribution lines, lighting facilities and communication equipment.

v) Temporary Building Facilities

The temporary building facilities consist of ground preparation, temporary buildings (administration office, supervisor's dormitory, labor camps) and ancillary facilities (warehouse, repair shop, etc.).

vi) Construction Machinery Depreciation Charge

- All construction machines (Table IV-2-1) required for this Project will be brought from Japan, and the depreciation charges of such construction machines were calculated by reference to the depreciation charge calculation methods defined by the "Japan Construction Mechanization Association".
- In calculating the depreciation charge of construction machines, a period of 2 months required to transport machines from Japan to the Site, and another period of 2 months for bringing back the machines to Japan, or a total of 4 months were added.

vii) Transportation of Machines

The cost of transportation of construction machines was calculated based on the following items based on assumption that all construction machines required for this Project (Table IV-2-1) are to be transported from Japan.

The unit cost are used based on the 1991 prices in Japan, Thailand and Laos.

- * Crating cost: 66.2 US\$/m³
- * Cost of loading in Japan (including inland transportation cost in Japan): 3 US\$/m³
- * Marine transportation fee (including all costs from Japan to Bangkok): 105.8 US\$/m³

IV-2-26

()

(1)

- * Inland transportation cost in Thailand: 117 US\$/t for reinforcing bars, 78 US\$/ m^3 for other items.
- * Inland transportation cost in Laos: 0.07 US\$/t-km
- * Insurance premium

viii) Expenses on Common Equipment

As expensed on common equipment, the cost of 100% depreciation was included for each of following equipment.

Item	Number
Light van	1
Jeep	3
Microbus	2
Light truck	1

ix) Cost of Safety Measures

1% of the temporary facility costs (the sum of items "i" through "viii" above) was counted as the cost for taking safety measures required for the construction work.

Beside, expenses related to inhabitant's safety measures which will be discussed in the Clause IV-5 "Environmental Influences" are to be included in this clause.

x) Others

10% of the above temporary facility costs, "i" through "ix", was counted as other temporary facility costs.

c) Overhead Costs

The overhead costs consisted of the technical personnel dispatching cost, expenses at construction site, and administrative.

i) Technical Personnel Dispatching Cost

This Cost is expenses for sending technical personnel of specific discipline (Japanese nationals directly involved in construction works at the Project side) — who are not available in Laos — from Japan. The Technical Personnel Dispatching Cost consists of a Direct personnel Cost, Airfare (round trip from Japan to Bangkok to Vientiane to Pakse and vice versa), lodging/boarding expenses and perdiem. These standards were duly referred to actual cases for other ODA projects of Japan, except for provision of airtickets (intermediate class). When dispatched technical personnel stay at the same location for a long period, the lodging/boarding cost and per-diem were discounted by 10% from the standard from the 31st day after the next day of arrival, and by 20% after the 61st day.

ii) Expenses at Construction Site

The direct personnel costs of Japanese technical personnel belonging to contractors who are stationed at the construction site or temporarily engaged in supervisory work, and locally hired personnel (technicians, typists, drivers, laborers), the associated direct expenses (air travel cost, lodging/boarding cost, per-diem), and the expenses incurred on the site office (office equipment, miscellaneous expenses, communications expenses, sundries, etc.) have been included. iii) Administrative Expense

10% of the direct construction cost plus technical personnel dispatching cost was counted.

d) Equipment for Civil Works and Associated Job

It was assumed that all gates, screens and valves are imported from Japan as completed products, and the 1991 prices of these equipment, transportation costs (in the same manners as the machine transportation cost) and the installation costs have been included.

e) Penstock

The FRP pipes and steel pipes (including lining steel pipes) have been assumed to be imported as completed products from Japan, similarly to the equipment for civil works and associated job, and the 1991 prices of these equipment, transportation costs (in the same manner as the machine transportation cost) and the installation costs have been included.

(2) Electro-Mechanical Equipment Construction Cost

- a) All components of electro-mechanical equipments such as turbines generators, main transformers, switching gears and control and protective equipments were assumed to be imported as completed products from Japan.
 - The cost of these facilities was estimated by what was referred to actual market price for them used in electricity utility in Japan.
- b) Transportation Cost and Insurance

These costs consist of two items, one is marine transportation and another one is inland transportation. Marine transportation cost was estimated as 6% of FOB value and it includes all transportation insurance from Japan to construction site.

Inland transportation cost was estimated based on trucking.

c) Erection Cost

All installment and adjustment cost are included in each facility price. Therefore erection cost consists of; 2 man-months of Japanese engineer for performance tests; 30 man-month of foreign engineer for construction work; 120 man-months of Laotian engineer for construction work.

In addition, unit cost (\$/kW) of this project is high due to smallscale hydroelectric power station, therefore in order to reduce this cost ordinary facilities available were fully chosen.

- (3) Transmission Construction Cost
 - a) Material Cost as Cables (Conductors), Insulators, Arms, Overhead Ground Wire, etc.

These material cost were assumed to be imported as completed products of 1991 price from Japan transportation cost was estimated base on same condition of 2.3.2(5).

b) Material Cost of Concrete Pole produced and procured in Lao PDR

Concrete poles as transmission supports will be procured in Pakse, and transportation cost from there to construction sites are estimated based on trucking.

c) Installation Cost

Installation cost was assumed based on the conditions as; one group consists of 22 engineers and/or skilled workers; it would

spend 4 days for 1 km distribution line; labour cost was estimated by actual data in Lao PDR.

In addition, the road of 20 km distance from Xe Katam Hydro Power Station to the Xe Kong River will be completed by the time of beginning of this work.

(4) Costs of Detailed Design and Construction Supervision

This Cost includes all costs to be incurred in preparation of tender documents including contract forms, technical specifications, drawings, etc., evaluation of bid proposals, checking of manufacturer's drawings, attendance at shop tests and construction supervision. The said Cost has been calculated as 15% of the above-mentioned cost of Civil Construction Cost, Generation Equipment Installation Cost and Transmission Line Construction Cost in the foreign currency portion and 10% of the same items in the local currency portion.

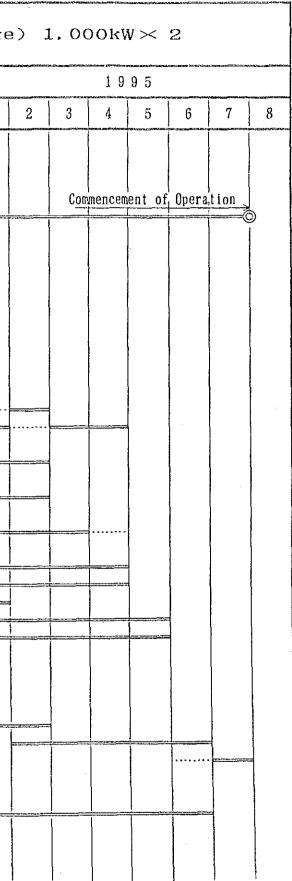

(5) Contingency

10% of the civil construction cost, power generation equipment construction cost and transmission line construction cost are counted as contingency.

(6) Interest During Construction

The cost estimate has been calculated by assuming that the annual rates of interests payable on the investments in each year during the construction period are 0.75% in the First Stage and 6.6% in the Latter Stage in the foreign currency portion, and 6.30% in the First Stage and 7.0% in the Latter Stage in the local currency portion.

3. Economic Evaluation

3.1 Method of and Assumptions for Economic Evaluation

3.1.1 Method of Economic Evaluation

The Xe Katam Small-Scale Hydroelectric Power Development Project (hereinafter called the "PROJECT") envisages construction of a hydro power plant and associated facilities including transmission lines with a final installed capacity of 6,000 kW as an isolated power system for supplying electricity to Sekong, Attapeu, etc. For achieving this goal, investments are to be made for construction/ installation/erection of civil structures, electro/mechanical equipment and transmission lines with an installed capacity of 2,000 kW in 1993 and subsequent two years. It is assumed that investments will also be made for facilities of 2,000 kW each which are expected to be constructed in 2001 and 2011 respectively in correspondence with the growing demand in Sekong, Attapeu, etc.

Based on the above-mentioned requirement, the economic evaluation has been performed by converting the Benefit and Cost stated below to present values thereof at the beginning of the first year (1993) when the investments for the implementation of the PROJECT commence to be made with the aim of finding values of Benefit-Cost and Benefit/Cost Ratio. At the same time, the economic evaluation has also been made by calculating an economic equalizing discount rate (EEDR) which makes a present value of Benefit and that of Cost equalized.

Cost : (1) Total Investment Cost for the PROJECT

- (2) Operation and Maintenance Cost after completion of equipment/facilities
- Benefit: (1)

It is assumed that diesel power plants having the same scale as that of the PROJECT on a comparable level are to be installed at the load centres of Sekong, Attapeu, etc. Total Investment Cost for these alternative diesel power plants are taken into consideration.

(2) Operation and Maintenance Cost after completion of such diesel power plant facilities. (3) Fuel cost to be accrued in correspondence with the quantity of required energy demand at a bus point of 22 kV transmission line.

3.1.2 Assumptions for Economic Evaluation

Calculations for the economic evaluation were worked out according to the following conditions:

- (1) Price level and escalation
 - All prices are as of 1991. No escalation rate is taken in calculations according to general principles of economic evaluation.
- (2) Conversion rates
 - US\$ 1 = Kip 700 US\$ 1 = Yen 136

(3) Service life

The facilities contained in the PROJECT are mainly composed of civil structures, electro/mechanical equipment and transmission facilities. No clear-cut stipulations are made in the Lao Accounting Code in connection with individual service lives of the said equipment and facilities. Therefore, the following standards were set up by reference to stipulations in Japan and other overseas countries.

(a)	Civil Structures	58 years
(b)	Electro/Mechanical Equipment	23 years
(c)	Transmission Facilities	27 years

The average weighted service life was calculated, using the percentage of the respective facilities and equipment from (a) to (c) accounted for in the total amount of investments for the 6,000 kW facilities. The calculation has resulted in 40 years which is equivalent to the composite service life of the PROJECT. On the other hand, the service life of the diesel power plant has been determined to be 20 years according to Lao practice.

(4) Discount rate

As for the discount rate, 10% is to be used as a result of consultation with the Lao side.

(5) Conditions for calculations for economic evaluation

The conditions for calculations inclusive of (1) through (4) above are shown in Tables IV-3-1 and IV-3-2. The values of the respective items except for those for fuel were not made available by the Lao side during the JICA Team's visit to Laos in July 1991. Therefore, appropriate values are cited by reference to those of similar items in other developing countries.

	Description	PROJECT	Diesel
(1)	Rated Output (kW)	6,000	6,496 (=6,000x1.08)

IV-3-5

3.2 Cost

3.2.1 Total Investment for the PROJECT

The total amount of investments for the PROJECT with a final installed capacity of 6,000 kW amounts to $24,875 \times 10^3$ \$ as shown hereunder:

Investment for PROJECT implementation

			(10 ³ \$)
	FC Portion	LC Portion	<u>Total</u>
2,000 kW (a) (lst stage)	13,103	2,291	15,392
2,000 kW (b) (2nd stage)	6,283	302	6,585
2,000 kW (c) (3rd stage)	2,876	20	2,896
Final Installed Capacity 6,000kW	22,262	2,613	24,875

3.2.2 Operation and Maintenance Cost

The ratio of the operation and maintenance cost of the PROJECT to its total investment (construction cost) is estimated to be 1.5% on a yearly basis. Therefore, 223 x 10^3 \$ after commissioning of the first completed 2,000 kW facilities of the hydro power plant, 319 x 10^3 \$ upon completion of the second completed 2,000 kW hydro facilities and 361 x 10^3 \$ for the third completed 2,000 kW hydro facilities to reach 6,000 kW are estimated to be accrued annually.

3.3 Benefit (Alternative Diesel Power Plant)

3.3.1 Investments for Alternative Diesel Power Plant

The installed capacity of the diesel power plant equivalent to 6,000 kW of the PROJECT is 6,496 kW. The total amount of investment for the alternative diesel power plant is to be 6,496 x 10^3 \$ which is obtainable by multiplying

6,496 kW by \$1,000, construction cost per kW. At each stage, 2,166 x 10^3 is to be invested during the entire service life of the PROJECT. However, the diesel power plants installed at the second and third stages will still have extra service lives at the last year of depreciation of the PROJECT. Accordingly, the residual cost was calculated by the following equation and subtracted so as to make an adjustment of investment costs between both schemes.

 $-(6/20 + 16/20) \times (1,516 + 650) = -2,382$

3.3.2 Operation and Maintenance Cost

The ratio of the annual Operation and Maintenance Cost of the diesel power plant to its total investments amounts to 4.5%. After commissioning of the first 2,000 kW of the PROJECT (corresponding installed capacity of the diesel power plant: 2,165kW), 97 x 10^3 \$ is to be needed as the Operation and Maintenance Cost annually. Likewise, 195 x 10^3 \$ and 292 x 10^3 \$ will be needed respectively after completion of 4,000 kW and 6,000 kW facilities of the PROJECT.

3.3.3 Fuel Cost

(1) Unit price of fuel

JICA Team visited the Pakse Branch and Head Office of the State Fuel Company in July 1991 in order to know the particulars and prices of diesel oil actually being used at existing diesel power plants in Sekong and Attapeu. It was found that the diesel oil being used at these power plants is of a standard quality, as shown in (11), (12) and (13) of Table IV-3-1. The unit price of diesel oil was approximately 270 Kip per litre. However, it was informed that around ten (10) percent of the diesel oil price was subsided by the Government. The amount of government subsidy was excluded according to general principles of economic evaluation. Consequently, 300 Kip per litre is to be used as the unit price of the Fuel Cost. Accordingly, the unit price of fuel per kWh can be calculated to be \$0.125 as shown below:

	Thermal Efficiency	Specific Gravity
860 Kcal/	0.34 /10,200 Kcal/	0.85 = 0.292 litre/kWh
0.292 litre	e x \$0.429/litre =	\$0.125/kWh

(2) Quantity of energy to be generated at diesel power plant

It is needed for the diesel power plant to generate the quantity of energy which will meet the quantity of "Saleable Energy" as shown in Table IV-3-2. Therefore, the fuel cost of the diesel power plant was calculated as given hereunder, assuming that the station service rate is to be 3%.

Saleable Energy × $\frac{1}{(1-0.03)}$ × \$0.125/kWh = Fuel Cost (10³\$)

3.4 Economic Evaluation

The streams of Benefit and Cost are shown is Table IV-3-3. B-C and B/C Ratio are as given hereunder:

Discount rate = 10%B-C : 1,365 x 10^{3} \$ B/C : 1.08 EDR : 10.80%

As can be seen from the B-C and B/C Ratio given above, the implementation of the PROJECT is more economical than the alternative diesel power plant scheme which will provide the same level of services. These figures indicate that the superiority can be maintained until a social discount rate which reflects the opportunity cost of capital in Laos reaches 10.80%. Table IV-3-3 Economic Evaluation

The following is the results of sensitivity analysis regarding variations in the construction cost of the PROJECT and those in the fuel cost of the alternative diesel power plant.

(1) Variations in Construction Cost of the PROJECT

(discount rate : 10%)

Construction Cost	<u>Up 32</u>	<u>Up 52</u>	<u>Up 72</u>	<u>Up 92</u>
B-C (10 ³ \$)	831	474	118	-238
B/C	1.045	1.025	1.006	0.988

(2) Variations in Fuel Cost of Alternative Diesel Power Plant

(discount rate : 10%)

Fuel Cost	<u>Up_3%</u>	<u>Up 52</u>	<u>Up 72</u>	<u>Up 9%</u>
B-C (10 ³ \$)	1,797	2,085	2,373	2,661
B/C	1.101	1.117	1.133	1.149

4. Financial Analysis

4.1 Methods and Basic Conditions for Financial Analysis

4.1.1 Methods of Financial Analysis

The financial analysis was made according to the following two (2) methods.

(1) Financial Analysis Viewed from Total Amount of Investments

A discount rate which makes the present value of operating revenue to be raised following the commissioning of the plant and associated facilities upon completion of the PROJECT equalized with that of the total cost (investments and operation and maintenance costs) is to be found. This discount rate obtainable is to be compared with a social discount rate which duly reflects the opportunity cost of capital in Laos. In this kind of comparisons, no consideration is given to annual interest rates to obtain borrowed funds, repayment period, payment and repayment conditions, etc.

(2) Financial Analysis Viewed from Standpoint of Project Equity

As far as an enterprise or agency for the implementation of the PROJECT is concerned, somewhat managerial guidelines and/or targets will be needed in obtaining funds, maintaining the completed plant, associated facilities and the like. For this purpose, the projected amortization schedule, profit and loss statement and cash-flow sheet were prepared so that debt service ratios to serve as a managerial criterion can be computed.

In performing the study from the two standpoints; considerations were given to the very fact that the Lao Government anticipates the most favoured fund accommodation for construction of 2,000 kW at the earlier stage, and they do not compile any investment budgets in their national development plan. Accordingly, the study was made on two cases; a case in which the amount of investments for the 2,000 kW facilities of the PROJECT at the earlier (first) stage is counted and the other case in which the most favoured fund accommodation is made for the said facilities.

4.1.2 Basic Conditions for Financial Analysis

(1) Conditions for Financial Analysis in View of Investments

a) Construction Cost

2,000 kW (1st stage)15,3942,000 kW (2nd stage)6,5852,000 kW (3rd stage)2,896		(10 ³ USS)
	2,000 kW (lst stage)	15,394
2,000 kW (3rd stage) 2,896	2,000 kW (2nd stage)	6,585
	2,000 kW (3rd stage)	2,896

Final Installed Capacity 6,000 kW 24,875

b) Operation and Maintenance Cost

As explained in the "Economic Evaluation" in 3, the annual operation and maintenance cost was calculated on assumption that it is to be equivalent to 1.5% (0.01452) of the total construction cost. Accordingly, $15,394 \times 10^3$ \$ $\times 0.01452 = 223 \times 10^3$ \$ is needed annually until the commissioning of the second 2,000 kW plant. Upon realization of 4,000 kW plant, the annual operation and maintenance cost will amount to $21,979 \times 10^3$ \$ $\times 0.01452 = 319 \times 10^3$ \$. Then, $24,875 \times 10^3$ \$ $\times 0.01452 = 361 \times 10^3$ \$ will be finally needed on a year-wise basis for operation and maintenance of the 6,000 kW plant.

- c) Energy Sales Revenue
 - i) Sale Rate

The following figures of the energy sales revenue and the quantity of sold energy for domestic use were made available by EDL to the JICA Team on the occasion of the said Team's visit to EDL headquarters in July 1991.

IV-4-2

	Revenue (10 ³ \$)	Energy Sold (GWh)	Average Sale Rate per kWh (Kip)
1986	3,530,100	805	4.38 (\$0.040)
1987	2,021,490	529	3.82 (\$0.040)
1988	5,565,100	508	10.95 (20.029)
1989	10,966,170	639	17.16 (\$0.024)
1990	15,287,570	789	19.40 (\$0.028)

EDL's records of the average sale rate/kWh shown above range from \$0.02 to \$0.03. Nevertheless, such sale rates include some amounts of government subsidy. EDL is contemplating reviewing this subsidy system and willing to set up a reasonable level of electricity charges in the future. It is the JICA Team's understanding that EDL was trying to take up 42 Kip (\$0.06)/kWh as a sale rate for the domestic use. Ιf compared with the sale rate 191 Kip (\$0.27)/kWh of provisionally calculated in the SPE-II report, it is considered that the sale rate of 42 Kip/kWh is still extremely cheap. Therefore, the said average sale rate of 42 Kip/kWh recommended by EDL has been taken up in the Financial Analysis.

ii) Estimated Quantity of Sold Energy

The figures of saleable energy given in Table IV-3-2 give a quantity of energy available at the bus-point of 22 kV transmission line. In view of the existing distribution lines in Sekong, Attapeu, etc. a distribution loss rate from the said bus point is estimated at 1% thereby calculating the quantity of energy sold at ultimate consumers in the above localities.

(2) Conditions for Financial Analysis from the Standpoint of an Enterprise

a) Conditions for Raising Funds for 2,000 kW: (1st stage):

i) Foreign Currency Portion

Annual Interest Rate	:	0.75%
Grace Period	:	10 years (counted from L/A date)
Repayment Period	:	20 years
Repayment Mode	:	Equal Amount of Principal

ii) Local Currency Portion

Annual Interest Rate	:	6.3%
Grace Period	:	10 years (counted from Sanction
:		date)
Repayment Period	:	20 years
Repayment Mode	:	Equal Amount of Principal
		Annual Repayment

Annual Repayment

b) Conditions for Raising Funds

Latter Period (2nd and 3rd stages) 4,000 kW (2,000 kW + 2,000 kW)

The following conditions were laid down since it seems that the Lao side expects multilateral financial assistance for the construction of 4,000 kW plant in the latter period except for the funds for the construction of the 2,000 kW facilities in the 1st stage.

i) Foreign Currency Portion

Annual Interest Rate	:	6.6%
Grace Period	:	7 years (counted from L/A date)
Repayment Period	:	20 years
Repayment Mode	:	Equal Amount of Principal
	•	Annual Repayment

ii) Local Currency Portion

Annual Interest Rate	:	7%
Grace Period	:	7 years (counted from Sanction
		date)
Repayment Period	:	20 years
Repayment Mode	:	Equal Amount of Principal
		Annual Repayment

c) Customs Duties, etc.

No customs duties, levies and taxes are not included in the construction cost.

d) Depreciation

The depreciation amount was calculated by the straight line method with a salvage value of zero.

e) Operation and Maintenance Cost

The annual operation and maintenance cost was calculated as 1.5% of the total construction cost. (Refer to 4.1.2 (1)-b for details)

f) Energy Sales Revenue

Refer to 4.1.2 (1)-c).

g) Escalation

Sec.

The costs were calculated as of 1991 and no escalation is considered.

(1) Financial Equalizing Discount Rate

a) Case in which the amount of investments for the 1st 2,000 kW is counted.

The equalizing discount rate can be calculated at 2.68%, far below a social discount rate of 10% which is a criterion for project evaluation in Laos, as shown in Table IV-4-1.

b) Case in which the amount of investments for the 1st 2,000 kW is not counted (regarded as null).

The calculations were made on assumption that the amount of the investments for the construction of 2,000 kW facilities at the first stage is not counted. However, an operation and maintenance cost is to be accrued regardless of any nature of funds raising. Therefore, the amount of such operation and maintenance cost was summed up. As a result, FEDR resulted in 14.28% for exceeding the social discount rate of 10%.

(2) Variations in FEDR by Sensitivity Analysis

The sensitivity analysis of the PROJECT was made on the following cases.

a) Case in which the amount of investments for the 1st 2,000 kW is counted.

- Variations in Construction Cost

Construction Cost	<u>Up 5%</u>	<u>Up_7%</u>	<u>Up 10%</u>
FEDR (I)	2.368	2.225	2.071

- Variations in Sale Rate

Sale Rate (Kip/kWh)	80	100	130
FEDR (%)	7.157	8.953	11.329

b) Case in which the amount of investments for the 1st 2,000 kW is not counted (regarded as null).

- Variations in Construction Cost

Construction Cost	<u>Up 10%</u>	<u>Up 20%</u>	<u>Up 30%</u>
FEDR (Z)	11.80	10.00	8.589

- Variations in Sale Rate

<u>Sale Rate (Kip/kWh)</u>	<u>30</u>	35	<u>40</u>
FEDR (Z)	7.416	10.00	12.925

(3) Debt Service Ratios

The debt service ratios were calculated on the following cases.

• Case in which the amount of investments for the 1st 2,000 kW is counted

- Case in which the amount of investments for the 1st 2,000 kW is not counted (regarded as null).
- a) Projected Overall Amortization Schedule
 - Table IV-4-3 shows the projected overall amortization schedule for the case in which the amount of investments for the 1st 2,000 kW is counted.
 - ii) Table IV-4-7 shows the projected overall amortization schedule for the case in which the amount of investments for the 1st 2,000 kW is not counted (regarded as null).
- b) Profit and Loss Statement and Cash-Flow Sheet
 - i) Table IV-4-5 through Table IV-4-6 give the Profit and Loss Statement and Cash-Flow Sheet for the case in which the amount of investments for the 1st 2,000 kW is counted.
 - ii) Table IV-4-8 through Table IV-4-9 give the Profit and Loss Statement and Cash-Flow Sheet for the case in the amount of investments for the 1st 2,000 kW is not counted (regarded as null).
- c) Debt Service Ratio
 - i) Case in which the amount of investments for the 1st 2,000 kW is counted.

The debt service ratios for the above case are laid out in Table IV-4-10. The average debt service ratio during the respective 10 years counted from the commissioning of the plant is as given hereunder:

10th year	from	the	commissioning:	0.53
20th year	from	the	commissioning:	0.51
30th year	from	the	commissioning:	0,75

ii) Case in which the amount of investments is not counted (regarded as null).

The debt service ratios for this case are laid out in Table IV-4-11. The average debt service ratio during the respective 10 years counted from the commissioning of the plant is as given hereunder:

10th year	from	the	commissioning:	1.73
20th year	from	the	commissioning:	0.74
30th year	from	the	commissioning:	0.97
40th year	from	the	commissioning:	1.49

(4) Generating Cost

A generating cost equaling to and comparable with a "manufacturing cost" of goods will be an important factor for electricity utilities in determining their sale rate(s). In this sense, average generating costs/kWh of the hydro power plant and associated equipment and facilities over the service life of 40 years have been calculated as follows for the two (2) cases:

a) Case in which the amount of investments for the 1st 2,000 kW is counted.

Total Quantity of Generated		
Energy over 40 Years	:	1,015,844 MWh
• Depreciation Amount	:	$25,773 \times 10^3$ \$
		(= Construction Cost;
		$24,875 \times 10^3$ \$ + IDC;
		898×10^{3} \$)
• Working Interest	:	$12,903 \times 10^3$ \$
• Operation and Maintenance Cost	:	$13,185 \times 10^3$ \$
Total		51,861 × 10^3 \$

 $51,861 \times 10^{3}$ (1,015,844 × 10^{3} kWh) = \$0.0511/kWh (= Kip 35.74)

b) Case in which the amount of investments is not counted (regarded as null).

Total Quantity of Generated		
Energy over 40 Years	: 1,015,844 MWh	
• Depreciation Amount	: 10,094 × 10^{3} \$	
	(= Construction Cost	
	9,481 × 10 ³ \$ + IDC	;;
	613×10^3 \$)	
• Working Interest	: $8,778 \times 10^3$ \$	
• Operation and Maintenance Cost	: 13,185 \times 10 ³ \$	
Total	$32,057 \times 10^{3}$ \$	
$32,057 \times 10^{3}$ (1,015,844 × 10^{3} kWh)	= \$0.0316/kWh (= Kip 22.09)	

4.2 Conclusions of Financial Analysis

It can hardly be said that this PROJECT is financially sound in terms of the equalizing discount rate. It will be indispensable to rely upon the specially arranged most favoured fund accommodation for construction of the first 2,000 kW plant in order that FEDR of the PROJECT can exceed the social discount rate of 10% which the Lao side has as its criterion in project evaluation.

When viewed from the standpoint of power utilities, it is essential that an ample amount of revenue be obtained through the materialization of the PROJECT. Under the sale rate of 42 Kip taken up in this Study, profitability obtainable from sales of energy is quite severe. A great increase in the sale rate will be necessary for improving this profitability. If such hike should be avoided, it will be necessary to obtain specially arranged most favoured funds for the construction of the 2,000 kW plant at the first stage and borrow funds at the lowest rate as much as possible for the construction of 2,000 kW plant each in the second and third stages.

5. Environment

5.1 General

5.1.1 General Description of Project Area

Champassak Province is one of the larger provinces in the southern Laos and the area of this province lying east of the Mekong River is bounded on the north by Xe Don River and on the east and southeast by the Xe Kong River. East of Pakse there is spread out the vast Bolaven plateau.

The Bolaven plateau is a conical shaped lava tableland, the elevation of which reaches EL. 1,000 m, the highest peak being as high as 1,716 m. The area of the plateau higher than EL. 500 m is estimated to be approximately 4,500 km². The watersheds of the rivers and streams running through the Bolaven plateau are mostly covered by good-quality, natural, tropical deciduous and semideciduous seasonal trees. Savanna areas with scrub trees are seen at top areas of the tableland. The Bolaven plateau is the source of numerous tributaries and torrents which feed the Xe Don River and the Xe Kong River which are major tributaries of the Mekong River, and is favored with abundant water resources and hydroelectric potentials.

The rainy season in this area is, in general, from May to October and the dry season from November to April. The average annual rainfall from 1984 to 1990 is approximately 2,500 mm at Nikhon 34 station (EL 1,150 m) close to the Xe Katam River basin. The maximum record of monthly mean temperature was 21.3°C in July and the minimum 15.8°C in January.

5.1.2 Basic Concept of Central Lao Government Regarding Environment

The Lao Central Government, in view of the importance of environmental issues, has deepened its interest in protection and preservation of forest resources, wildlife and water resources.

At present, the Central Government is preparing the inventory of forests from a view point of conservation of the environment and also undertaking the program or activity to preserve wildlife, as well as preparation of environmental regulations or codes. While the provincial offices, in line with the basic concept of the Central Government, are providing administrative guidance to villagers to limit the slash-and-burn farming to the minimum extent and to maintain natural resources in good condition as much as possible by methods such as forestation programs and settled agriculture.

5.1.3 Xe Katam Small-scale Hydroelectric Power Development Project and Environmental Setting

The Xe Katam Small-scale Hydroelectric Project is planned near the confluence of the Xe Namnoy River which is a tributary of the Xe Kong River and the Xe Katam River.

The diversion site proposed on the Xe Katam River is located 1,000 m upstream of the abovementioned confluence. Immediately downstream of this site there are two waterfalls, the one is small with about 20 m in its cascade and another is large of about 100 m in its head. The powerstation is planned on the Xe Namnoy River at a point approximately 400 m upstream of the confluence. The diversion site and the power station will be connected by a headrace tunnel of approximately 320 m.

The discharge after power generation will be immediately returned to the Xe Namnoy River. The river section affected by diverting water for power generation will be only the approximately 1,000 m from the diversion site on the Xe Katam River to the junction point. Water use for irrigation, drinking water, fishing, etc. is not found at present in this section. Further, the projected sites for the diversion, headrace tunnel, powerstation, transmission line, etc. and their vicinities - project area- are covered by natural tropical forests, and there are no villages nor cultivated fields. Accordingly, there will be no occurrence of troubles concerning moving of residents, loss of property and compensation.

Thus, since the scales of the structures comprising the Project are small and the impact on the river system is limited, the negative impact on the natural environment such as wildlife, forest resources, water resources, etc. due to the Project implementation will be extremely limited. There seems to be no prominent loss to cultivated fields and properties directly affected by the Project implementation.

It is imagined however that at the stage of construction of the Project, various negative impacts will occur during a limited period and in a limited area accompanying execution of construction works.

At the stages of construction works and operation of the power station, frequent exchanges between villagers will start to occur such as trading of various commodities including construction materials which did not exist prior to the Project in this area.

Such socio-economic activities will have considerable impact on the conventional concept of value among residents, and as a result, this may bring about changes in the daily pattern of living of the residents.

5.2 Natural Environmental Setting of Project Area

5.2.1 Forests and Vegetation in the Xe Katam River Basin

The left-bank watershed of the Xe Katam River, compared with the right-bank basin, generally comprises steep slopes, and these slopes continue up to the highest ridge from where the Xe Katam River rises.

At the right-bank watershed extending to the west and southwest of the Xe Katam River, except for the steep riparian areas along the Xe Katam, there are spreads of hills and plains with gentle relief at elevations of 800 to 1,000 m.

The mountainous basin, other than the plains used for agriculture and livestock raising, is covered by natural tropical deciduous seasonal forests or semi-deciduous seasonal forests with a dense or closed canopy of trees.

The forests consist of various species of trees, tall ones from 20 to 30 m high, middle and short 10 m and under.

The principal tree species are as listed in Table IV-5-1. Included along these are trees with commercial values corresponding to Grades 1, 2, and 3 in the lumber standard of Lao. The groves of tall bamboo are seen here and there in the Xe Namnoy and Xe Katam basins. So far as in the Xe Katam River basin where the reconnaissances were made in December 1990 and July 1991, trees fortunately have not been cut down in that area up to the present and verdant natural forests have been preserved untouched. However, it is reported by the aerial observation that farmlands reclaimed by slash-and-burn are distributed here and there in the watershed of Xe Katam River.

The central and local governments have undertaken campaign with strict control to villagers not to make slash-and-burn farming in verdant forest areas. As a result, acreage of farmland opened by means of slash-and-burn in Paksong District has decreased to approximately 300 ha in 1990/1991 which is a half of 700 ha in 1989/1990.

5.2.2 Wildlife in the Xe Katam and Xe Namnoy River Basins

It has been indicated by the survey of the Mekong Committee conducted in 1970 that 1,121 species of wildlife animals inhabit in the whole lower basin of Mekong River, and that there was possibility of precious species such as Kouprey and Douc Lungur live in this area. The Mekong Committee expressed strong interest in preservation of these wildlife animals.

There is a simple air-strip near Ban Houaykong. As the noise of airplanes is reduced in recent years, it seems that the environmental conditions for wildlife animals is returning better.

It is reported that mammals such as elephants, tigers, wild pigs, deer, monkey and hares, reptiles such as cobras, and various kinds of fowl inhabit in the Xe Katam and Xe Namnoy river basins at present.

Shooting and catching are not allowed by the ministry of agriculture for the animals which have become reduced in number and have been endangered recently. The wildlife animals among them deemed to inhabit in the said basins are as listed below. Of the wildlife animals, endangered elephant has been strictly protected from shooting in this region.

Pygmy Loris,Asia Elephant,Francois Langur,Gaur,Black Gibbon,Banteng,Tigar,Leopard,etc.

5.2.3 Fish and Shellfish in the Xe Katam and Xe Namnoy Rivers

According to the results of reconnaissances, fish and shellfish inhabiting in the Xe Katam and Xe Namnoy Rivers in the project area and the vicinity are few, both in variety and number. The names of fishes found in the two rivers are given in Table IV-5-2.

There are a small waterfall and a large waterfall, head of which is as high as about 20 m and 100 m respectively located approximately 700 m upstream from the confluence of the Xe Katam and Xe Namnoy Rivers. It may be said that these waterfalls act as a great obstacle to movement of fish between the two river systems.

The main sources of protein of the people in villages of the neighboring area are domestic fowl and small- to medium-sized animals. It is unlikely that fish is considered to be an important protein resource for villagers.

5.2.4 Water Resource of the Xe Katam River and Aquatic Impact

The catchment area at the diversion site is 290 km^2 , and the annual average runoff is approximately 290 MCM (average runoff 9.2 m^3 /sec). The gradient of the Xe Katam River in this vicinity is from 1/50 to 1/60 and the width of river bed at normal water level is estimated to be about 30 m. Gravels and boulders of basalt and/or shale are deposited over the river bed from upstream to downstream stretches.

According to the field investigations carried out in December of 1990 and July of 1991, the river water seems to be clear and odorless with no suspended sediment and the temperature was about 20°C. Table IV-5-3 indicates the results of quality analysis of the water collected in the Xe Namnoy and Xe Katam Rivers.

Water for power generation diverted from the Xe Katam River will be released into the Xe Namnoy River approximately 400 m upstream of the junction of the two rivers. The distance between the proposed diversion site and the confluence of the two rivers is approximately 1,000 m, and there may generally, be only a slight effect on the flow condition at this stretch due to intake the water for power generation.

However, in the driest season, water at the small fall and the adjacent large fall, which are respectively located immediate downstream of the intake structure, would be almost lost so that the present beauty of the falls might be diminished. Since there is no access to the said falls in the remote area, it is not regarded to be sightseeing spot up to the present.

Water use for irrigation, drinking, etc., does not presently exist, while the water diverted for power generation will immediately be returned. It is considered there will be no prominent negative impact on water resource.

5.3 Socio-economic Environmental Setting of Project Area

5.3.1 Village, Ethnic Group and Population

An area of gentle relief between elevations of 700 and 900 m is spread out to the west of the project area, and in this area are scattered 22 villages. The collection of these 22 villages makes up an administrative unit called a khet, and this unit belongs to Administrative District No. 5, Paksong District, Champassak Province.

The total number of households in this khet is 1,075, with the population being 5,052 (as of December 1990). Of this population, the labor force between ages of 16 and 50 numbers about 1,700.

It is reported that 10 ethnic groups are living in this khet. Two of them which are major may be said to be the Lavine and Nga Heun. Information concerning the villages of this khet is given in Table IV-5-4.

5.3.2 Land Use and Agriculture

Almost all of the people living in this khet are engaged in agriculture for their livelihood. Cultivated land is mostly used for growing coffee and rice. These farmlands were originally reclaimed from the forest by means of slashand-burn.

Almost all farmlands developed in this way are used for upland rice planting during the first one (1) year, after which they are converted to coffee fields. This method is different from conventional "shifting agriculture", by which burned lands reduce their productivity and are thereafter abandoned and thus forests are opened up one after another. Therefore, it may be said that the method adopted here will be along the lines of settled agriculture aimed at by the Central Government.

Since it takes about five years for coffee trees to grow to the productive ones, it is likely that some of villagers practice slash-and-burn farming for rice plating in order to get their food during the said period. While, the central and local governments, for the purpose of preserving good forests and keeping the environment impact minimum, have repeatedly undertaken their campaign to the villagers to open un-used swamp or depressed areas into paddy fields and/or low grade forests into rice fields as much as possible which give less impact on the environment.

Coffee fields amounted to 500.8 ha in area as of 1990, of which 265 ha were productive fields, the remainder still consisting of young non-productive shrubs. The production of coffee beans in 1989 was 220 tons, and sold in markets such as at Pakse for 350 to 380 kp. per kilogram, which is the only cash earning source for the villagers.

Next to coffee, the area is regarded to be rice producing zone in the Bolaven plateau and more than 30% of villagers are engaged in the rice (paddy and upland) production. Rice (upland rice and paddy) is grown for the purpose of home consumption and the cultivated area was about 442 ha including 388 ha reclaimed by slash-and-burn method as of 1990. It is said more than 80% of the area is planned to be converted to coffee fields.

The average yield of rice in the area is 0.8 to 1.0 ton/ha. It is said in the area that average 1.5 ton/ha of paddy can be expected in case the settled agricultural practice be executed. Farmers also raise chicken, pigs, cattle, and horses on a small scale.

Promotion of cattle husbandry seems important in this area in order to improve nutrient conditions and to enhance living standard of the villagers.

5.3.3 Endemic Diseases and Medical Facilities

The main endemic disease in this region is malaria. Population afflicted was reported to be not more than 3% in 1986, 1987 and 1988 and the malaria was outbroken and spread in the entire country in May, June and July of 1991. The affliction of malaria in this region was also greatly increased in the simultaneous period since that in 1989. Because this region is at elevations from 700 to 900 m and the temperature is relatively low, the rate of affliction is low compared with other regions of Laos. The ratio of the population suffering from malaria has been declining year by year due to increases in preventive injections. However, the outbreak of malaria with high rate has been still seen periodically.

It is said that the diseases caused by parasites are not such serious problems compared with other regions of Laos. Recently malignant diarrhea and various diseases caused by insufficient nutrition have been outbroken in the children of the villages.

First aid stations have been provided at 13 places in this khet, but there is an extreme shortage of medical staff. A medical facility playing a central role in this region is located at Ban Houaykong, where three medical staff are stationed to be engaged in medical services. 5.3.4 Education

una.

There are eleven 3-year and five 5-year elementary schools, and two middle schools in this khet. It was learned in interviews at a school at Ban Latsasin and Ban Houaykong that the percentage of school attendance of children of the villages is $70 \sim 80\%$, which means that the rate of school attendance is fairly high in this region.

5.3.5 Social Infrastructure and Trading Situation in the Region

Paksong, located at the center of the Bolaven Plateau, and Pakse, one of the largest cities of Laos next to the capital city of Vientiane, are connected by National Highway No. 23.

There is an arterial road still unpaved leading further east from Paksong to Ban Houaykong, the center of Administrative District No. 5. The distance between Paksong and Ban Houaykong requires 3 to 4 hours by automobile even in the dry season. There are sections of road in this stretch which are poorly maintained in the vicinity of Paksong, and traffic-particularly in the rainy season - is extremely difficult.

There are also routes to Paksong and Ban Houaykong going via Laongam located to the north of the Bolaven Plateau, but trafficable access roads from Sekong and Attapeu do not exist at present. A road network passable for small- and medium-sized trucks has been prepared within the khet.

This khet does not yet provide an electric power supply system, let alone telecommunications facilities such as microwave.

Only several households provide privately-owned gasoline generators operated for a mere 2 to 2.5 hours in the nighttime. Energy for cooking depends on firewood and dry twigs collected from nearby woodlands.

Scheduled buses ran between Pakse and Ban Houaykong every other day providing an extremely useful means of transportation, communication and trade at the reconnaissance time in December of 1990. Mainly agricultural products were transported out to Pakse and elsewhere using these buses, while from Pakse and
