

6.3 Travel Speed Survey

(1) Private Passenger Car Speed Survey

a) Method

Test-car method was applied for observing an average vehicular speed on selected road links. The drivers of test-cars drove the car at the average speed of the general traffic flow.

Running time recorders looked for the check points indicated on the route map and recorded the cumulated time from the starting point using a stopwatch. In addition, the distance was recorded by a trip meter of the test-car.

Stop and slow time recorders measured time during stops and slows. Time for deceleration is not included in slow time. Slow time was recorded only when the test-car moved forward but there was still queues in front. At the same time, reasons for stops and slows were recorded by the surveyor.

b) Survey Routes

Average travel speed was surveyed on the selected 10 routes as shown in Fig. 6.3.1.

c) Survey Period

The test-car departed from the starting points at 6:00, 8:00, 10:00, 14:00, 16:00, and 18:00. The first three runs were surveyed by the surveyors in the shift (1), and the last three runs were surveyed in the shift (2).

(2) Bus Speed Survey

a) Method

Bus operating speed was surveyed on board. The surveyors of the bus speed survey got on buses from the designated place and got off at the designated destination. When the surveyed bus passed the check points, the time passed from the origin place was recorded by the surveyors.

b) Survey Routes

Basically the same routes as those surveyed for general traffic flows were selected for the bus operating speed survey. However, some sections were omitted due to the limitation of the existing bus routes.

c) Survey Period

The bus speed surveyors also departed from the starting point at 6:00, 8:00, 10:00, 14:00, 16:00, and 18:00 for comparison between bus speed and general traffic flows.

(3) Survey Result

The travel speed survey results for the general vehicular speed and the bus operating speed were summarized in Table 6.3.1 and 6.3.2, and presented diagrammatically in Figs. 6.3.2 through 6.3.5.

CHAPTER 7 TRANSPORT MODELING AND DEMAND FORECAST

CHAPTER 7 TRANSPORT MODELING AND DEMAND FORECAST

7.1 Introduction

7.1.1 Basic Concept

This chapter sets forth techniques and methodologies of transport modeling processes employed during the course of this study. The travel demand forecasting model employed in this study has its root in the previous study, the 1985 Arterial Road System Development Study (ARSDS). The 1985 ARSDS transport models were verified in a cascading step as shown in Figure 7.1.1.

In the first place, present travel demand was estimated by applying a series of transportation models developed in ARSDS (1985) with 1993 socio-economic indicators. The estimated travel demand was compared with the observed traffic volume and passenger demand to examine an applicability of the previously developed transportation models for demand forecasting. Accordingly, the estimated mode-wise travel demand in the form of origin-destination matrices were calibrated to the observed traffic volume at the screen lines and cordon lines. Once "base year" network and matrices were set up, future network and matrices may then be developed, and traffic assignment routines performed.

7.1.2 Aggregations and Definitions

In a comprehensive study such as this project, it is necessary to adopt various techniques and terminology. The following descriptions are provided so that a more accurate and complete appreciation of study results and evaluations may be obtained.

- *Data Aggregations*

It is not possible to predict travel choice (routing and demand) individually for each study area trip. Aggregations of data are therefore necessary and desirable at several levels within the analytical process.

- *Study Area and Zone System*

The study area is subdivided into analysis zones, the use of which implies that all movement to and from a zone can be adequately represented as starting or ending at a single point in the zone - the centroid. This point represents the zonal center of transport activity.

Transport modeling is achieved using the Jabotabek transport model, which uses the Jabotabek area as its analytical foundation. Thus, trip demand is generated within and between Jakarta, Tangerang, Bogor and Bekasi. This study area was, to achieve degrees of accuracy, previously subdivided into 131 zones. Within Jakarta (90 zones), subdivisions are typically based on

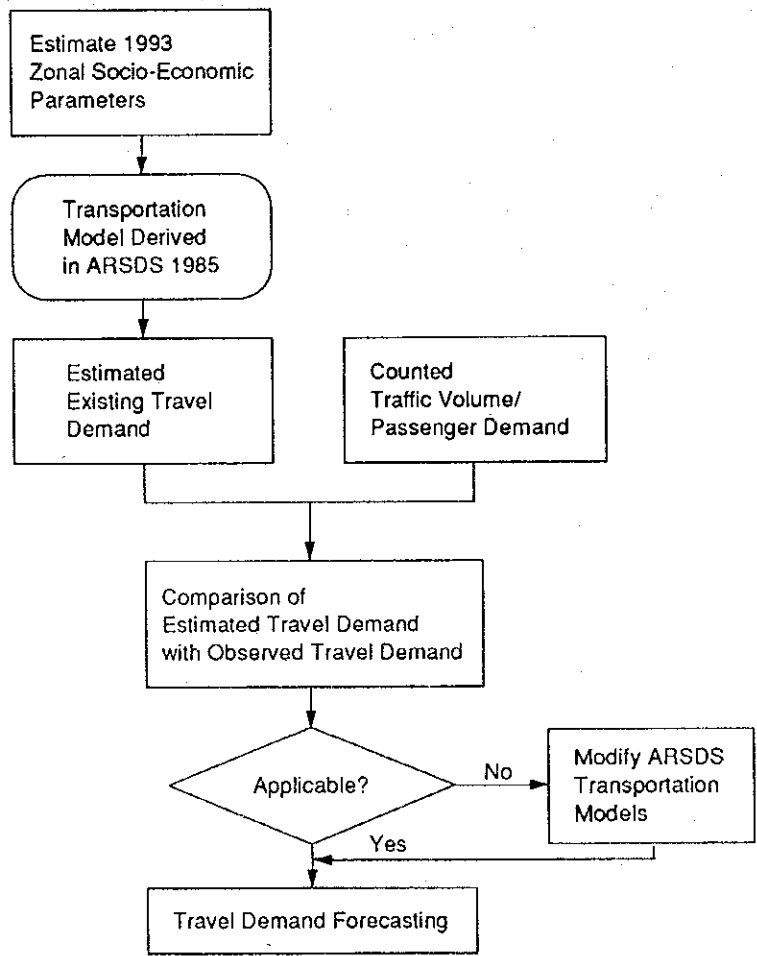

Fig. 7.1.1

Kelurahan boundaries; within Botabek (23 zones), Kecamatan or Kabupaten boundaries, and outside of Jabotabek (18 zones) Province boundaries. However, during the current study, some major updates were required as to :

- integrate recent changes in Kelurahan designations/naming with the zone system to ensure compatibility with recent data such as results of the 1990 census;
- expand the zone structure within Jakarta to allow for a more detailed traffic analysis;
- restructure zones in Botabek area; and
- designate a special zone to represent movements to/from Soekarno-Hatta airport.

As a result, a revised system of 202 (two hundred two) zones was created. The zone numbers, names and locations are presented in Table 7.1.1 while Figure 7.1.2 shows the 131-zone system (prior to zone division).

- *Vehicle type*
Feasibility and utilization analyses inherent to this study are based on over-the-road motorized vehicle trips subdivided into four categories, namely motorcycles, sedans (comprising private passenger cars, taxis, pick-ups and vans), buses (comprising small, medium and large-size buses) and trucks (comprising all trucks larger than pick-ups).
- *PCU equivalence*
A trip is defined as a one-way movement from an origin zone to a final destination zone. The trip may be completed as a vehicular trip (motorized form of transport) or as a "passenger car unit" (PCU). This stratification accepts that vehicle types will exert differing impacts upon the traffic stream in which they operate. Motorcycles are defined as being equivalent to 0.33 PCU, sedans to 1.00 PCU, trucks to 2.22 PCU and buses to 1.50 PCU.
- *Tollroad users*
Potential future users of tollroads are defined as all forms of motorized over-the-road transport whose utilization of the tollway is not precluded on policy or operational grounds. Motorcycles are excluded from the tollway user population, while buses, although some route license prohibit the use of tollway, may use the tollway subject to capacity restraint.
- *Planning Horizon*
The "base transport condition" is defined as that existing during year 1993. Future year demand is projected in detail for years 2000 and 2010. It should, however, be noted that the designation of an ultimate, long-horizon, year represents a somewhat artificial, if necessary, future-year

FEASIBILITY STUDY ON
 URBAN ARTERIAL ROAD SYSTEM DEVELOPMENT PROJECT
 IN JAKARTA METROPOLITAN AREA

Fig. 7.1.2 (a) TRAFFIC ZONE SYSTEM IN DKI JAKARTA

linkage. It is, from a transport perspective, more correct to state that future-year demand projections reflect the achievement of a stated socio-economic condition, which may or may not occur precisely in the postulated year.

7.2 Modeling Procedures

The procedures for transport demand modeling are conveniently illustrated in Figure 7.2.1, and explained accordingly in the following paragraphs. For the execution of these tasks, the capability of TRANPLAN/NIS¹ software were employed during all steps of the modeling process.

7.2.1 Zonal Planning Parameters

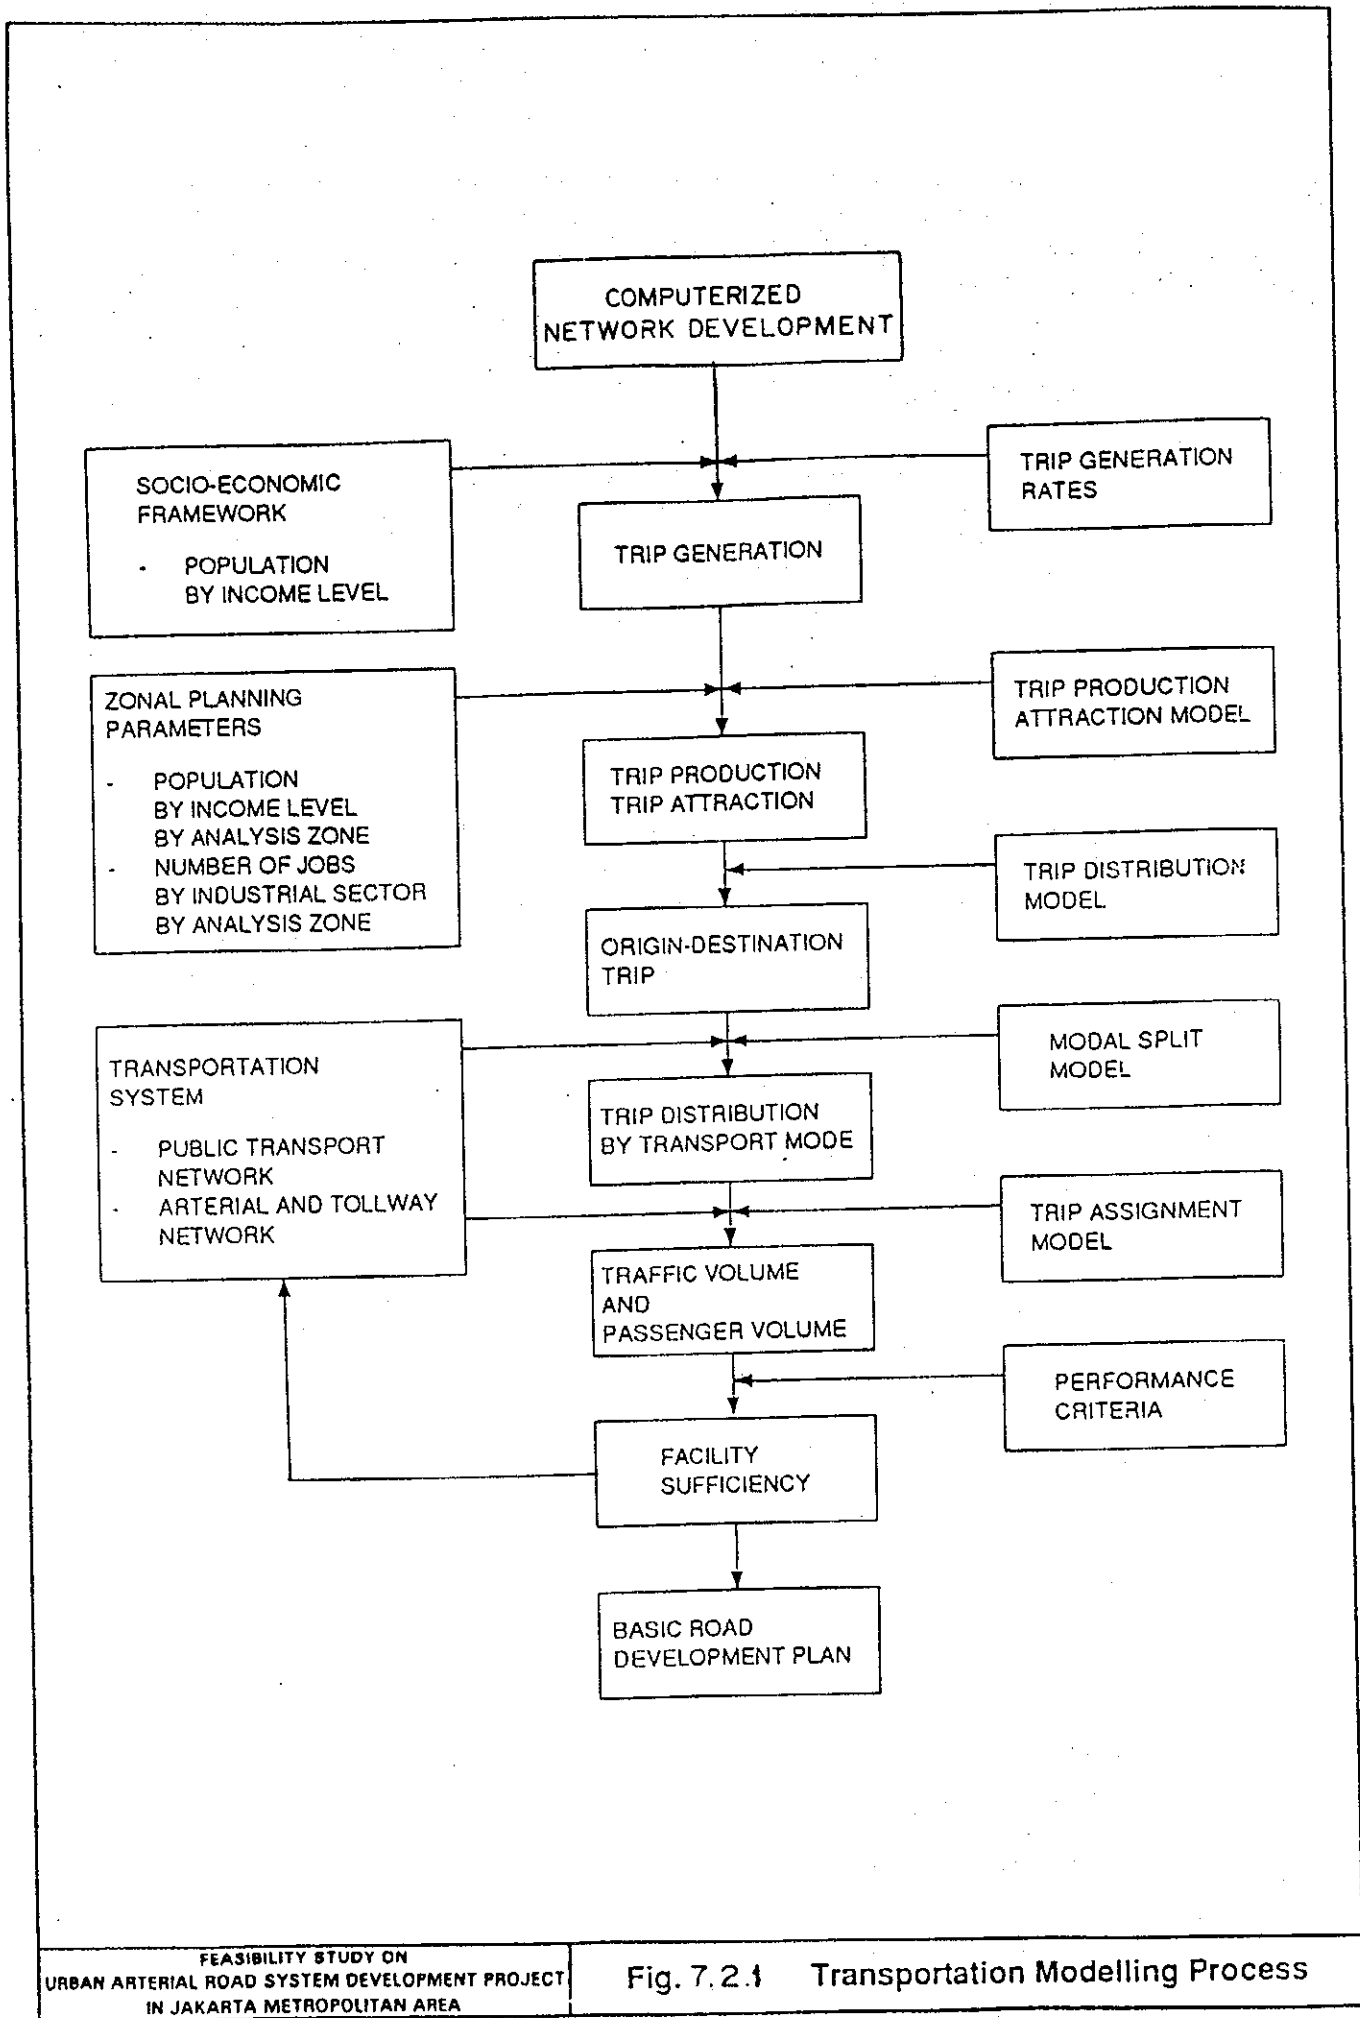

Zonal Residential Population

A zones allocation of residential population in DKI Jakarta and Botabek in 1993 was based on the growth trend derived from the 1980 and 1990 census results of respective traffic zones. The zonal estimates were finally adjusted to the number controlled for the 1993 total population in DKI Jakarta which was independently determined by the regional population growth trend in Jabotabek.

The zonal estimate in 2010 for DKI Jakarta was principally based on the DKI Jakarta Structure Plan. However, revisions were made comparing the planned figure with virtual pattern of population growth in the respective zones. The zones were first categorized into two groups, that is 1) population decreasing zones and 2) population increasing zones.

For the former category, causes that brought about the population decrease were investigated referring to the 1985 land use map (ARSDS results) and a 1990 general land use map prepared by the Bureau of Maps and Survey for DKI Jakarta. Based on the analysis result and a future district plan (RBWK), the population capacity was assumed for these population decrease zones for the future.

1) TRANPLAN (Transportation Planning Modeling Software) and NIS (Network Information System, a set of linket proprietary transportation planning programs distributed by The Urban Analysis Group, Danville, California, U.S.A.

As for the latter category, the virtual increasing trend, derived from 1971, 1980 and 1990 census results, was compared with the target population set by the Structure Plan, and the category was further divided into the following two sub-groups:

Sub-group (1) : the increasing trend is likely to reach the target population set in the structure plan

Sub-group (2) : the increasing trend is likely to either overestimate or underestimate the target population.

Zones pertaining to the sub-group (1) adopted the derived increasing trend, but those in the sub-group (2) were analyzed to find reasons that brought about differentials between the target figure and the actual figure. The analysis was carried out referring to land use changes between the year 1985 and 1990, and further 2005 of the district plan, in order to determine a revised capacity of settlement in the zones.

Consequently, the total population resulted from the above process was adjusted to conform with the future population determined externally from the regional context by the JMDPR. The derived zonal population is presented in Appendix 4A.

Zonal Distribution of Jobs

The number of zonal jobs is one of important factors to explain the trip attraction to the zone. Compared to the zonal population, basic data concerning to the job distribution are considered most difficult to obtain. The direct data can only be available from the 1986 Census Economy which covered locations and numbers of employees at sampled industrial establishments. However, the census does not include all the type of industrial activities, particularly such facilities without fixed addresses as street vendors and road side temporary restaurant and shops.

The indirect data or information which could indicate the job distribution are land use maps. Therefore, these two data sources were utilized to assume the present 1993 job distribution in both DKI Jakarta and Botabek.

The future distribution of jobs in DKI Jakarta was largely based on the district plans prepared for respective Kecamatans for the Year 2005. The zonal estimate for Botabek was undertaken by distributing the fixed total jobs of Botabek components according to the estimated urban/rural population, designated types of urban development such as primary, secondary and local service centers. The derived zonal distribution of jobs is presented in Appendix 4A.

7.2.2 Network Development

The development of base and future year network (both highway and transit) within the study area was performed in three cascading steps :

- analyze DKI Jakarta Public Works road inventory supplemented with field survey as well as any existing road development plans;
- digitize (assign two-dimensional coordinates) to selected links and nodes (generally excludes local roads) contained in the network; and
- develop computer-based networks utilizing capabilities of TRANPLAN/NIS modeling software.

Maps and Inventory Data

Maps and physical descriptive data for road links as well as transit operations were available from the following sources :

- Jakarta base map (digital format, from DKI Mapping Office);
- Jakarta 1993 road atlas (FALK map);
- Jakarta 1993 road inventory (Dinas PU DKI);
- DKI road map 1:20,000 (from former ARSDS study);
- Botabek topographical map 1:25,000 (BAKOSURTANAL);
- Bus operation information (DLLAJR DKI);
- DKI 2005 road development plan;
- Road development plan in Kabupaten Bogor, Tangerang and Bekasi;
- Road improvement implementation plan (Bina Marga & DKI)

These maps and information were observed thoroughly, and unnecessary roads (such as local road in housing area) were excluded from the network, thus leaving only the tollway, arterial, collector and so-called local-plus roads (local roads passed by public transport). Also included were the planned roads categorized as major arterial, minor arterial and major collector in the DKI 2005 plan.

System Digitizing

The road inventory identifiers were transferred to a 1:20,000 map covering the study area. Node and zone centroid numbers were subsequently assigned in line with TRANPLAN requirements. The road network, as well as visual identifiers such as kelurahan and zone boundaries, were then digitized. That is, the capabilities of AUTOCAD software were applied to assign 6-digit X and Y coordinates to each node. Thus, visual system displays are possible under a variety of mediums, including NIS.

Conversion to TRANPLAN format

The TRANPLAN highway network simulation programs require following information for each link :

- A and B node numbers (numeric values which identify the "from" and "to" node of the link),
- Link distance,
- Free flow speed,
- Link capacity,
- Assignment group code, and
- Link group code.

Following paragraphs describe the source/derivation of each of these link data items.

- a) A and B node locations are defined by their X and Y coordinates within Jabotabek area. The coordinate locations are obtained from the digitizing process.
- b) Link distance defines the length of a link in kilometer.
For simplification, distances are merely straight line distances between the A and B node.
- c) Free flow speed is defined as the safe speed at which a vehicle would travel on a link in the absence of other traffic. The average free flow speeds were estimated for each road type.
- d) Link capacity is defined in term of assignment capacity, which represents a trip-making threshold for modeling purposes at which alternative route choices (as practical and possible) are likely. This is generally adopted as a Level of Service C/D condition, as defined by the "Highway Capacity Manual, 1985".
Capacities of roads in urban area have been modified in such a way to account for the effect of delay by traffic signals.
- e) Assignment group (ASG) code is used to identify links to which a common capacity restraint function is to be applied; that is, link speed is reduced by a pre-determined function as the link volume to capacity (V/C) ratio increases. For TRANPLAN input, ASG codes were defined as follows (see Table 7.2.1).

Table 7.2.1 Assignment Groups for Jabotabek Trip Assignment

| ASG | FACILITY |
|-----|-------------------------------|
| 0 | Centroid Connector |
| 1 | Ramp |
| 2 | Urban 1 or 2 lane |
| 3 | Rural 2 lane |
| 4 | Urban Multi-lane |
| 5 | Urban Multi-lane (high order) |
| 6 | Rural Multi-lane |
| 7 | Urban Freeway |
| 8 | Rural Freeway |

The Capacity Restraint Functions (QV curves) are shown in Figure 7.2.2.

Figure 7.2.2 Capacity Restraint Function

f) Link group code is a numeric code to group links with common characteristics for subsequent referencing, updating, and reporting. Link groupings employed in this study address functional class, toll facility, and a special grouping for N/S and E/W Axis Roads.

g) Toll road Impedance

In addition to the above information, another important consideration is tollroad impedance, i.e. a factor via which the transport model routes, or does not route, trips onto the tollroad system. Impedance is determined not only by travel time, but also delays associated with toll transactions, deceleration/acceleration at toll booths and the impact of the toll itself. The latter item is problematic in that impedance is calculated in terms of time, thus, "toll paid" must be converted via a "*value of time*". The derivation

of a time conversion (ie the Rupiah value associated with one hour of travel time for composite tollway users) has always been difficult in Indonesia.

Value of time for different planning years have been calibrated during the course of Jakarta Outer Ring Road Section W1 project conducted by PCI (Pacific Consultants International) in early 90s. The calibration approach adopted within the framework of the ORR-W1 study consists of several steps :

- PCI conducted a traffic count program at locations sited strategically along tollroads, major arterials and the ORR corridor. Volume data were collected over 16-hour periods by direction, by 11 vehicle types and, where appropriate, segregated by tollroad mainline and frontage facilities. These data were supplemented by latest available utilization information for all facilities managed by PT. Jasa Marga.
- Calibrated trip matrices were assigned onto the road system, and modeled traffic volumes compared with observed traffic volumes at 23 locations throughout the tollroad system.
- Assignments were conducted iteratively with value of time modified in subsequent assignments based on comparisons of activity at the 23 tollroad calibration points.

Final results suggest that an acceptable simulation of tollroad activity can be achieved with base year value of time equal to 4750 Rupiah per hour. The future value of time is adjusted in two ways :

- Since the initial toll structure (of the ORR-W1 project) is expressed in terms of 1995 Rupiah, the 1992 impedance is extrapolated to a 1995 impedance in both inflatory (8% p.a.) and real (3% p.a.) terms.
- Post 1995 value of time will, relative to toll structure, change only in real terms (3% p.a. to 2005, 2.5% p.a. thereafter). In other words, an implicit assumption of the modeling process is that the financial "well being" (income) of tollroad users will exceed inflation (Jasa Marga toll rate increases) by some 2.3 to 3 percent p.a.

For the purpose of this Study, the base year value of time is assumed to be the same as that of ORR-W1, whereas the 2010 value of time was estimated via interpolation (see Table 7.2.2).

Table 7.2.2 Value of Time by Planning Years

| Year | V.O.T (Rp/hour) | Remarks |
|------|-----------------|--------------|
| 1993 | 4,750 | W1 |
| 1995 | 6,300 | W1 |
| 2000 | 7,300 | W1 |
| 2005 | 8,400 | W1 |
| 2010 | 9,500 | Interpolated |
| 2015 | 10,800 | W1 |

7.2.3 Trip Generation Model

Total person trip generation in DKI Jakarta and Botabek was estimated employing trip production rate shown in Table 7.2.3 by income group obtained in the ARSDS with estimated population data by income level.

By including income level as a factor of socio-economic parameters in the estimation process makes, it is possible to reflect an increase of travel demand caused not merely by an increase of population but also by an increase in mobility.

Table 7.2.3 Trip Production Rate

| Trip Purpose | Income Group | | | |
|-----------------|--------------|-----------|-----------|-------|
| | High | U. Middle | L. Middle | Low |
| To Work | 0.410 | 0.393 | 0.366 | 0.358 |
| To School | 0.242 | 0.252 | 0.244 | 0.200 |
| To Home | 0.929 | 0.873 | 0.799 | 0.729 |
| Business | 0.130 | 0.104 | 0.081 | 0.071 |

| Shopping | 0.119 | 0.113 | 0.119 | 0.121 |
| Total | 2.209 | 2.015 | 1.795 | 1.620 |

Source : ARSDS, 1985

7.2.4 Trip Production/Attraction Models

Trip production/attraction models derived in the ARSDS are classified into two types of forms;

- Attendance rates for "to work", "to school" trips; applied in order to reflect changes of age structure followed by change in labor force and school age population in the future.

Table 7.2.4 Zonal Socio-economic Parameters

| Variable Name | | Place |
|---------------|--|-----------------|
| POP-HI | Population in high income group | at residence |
| POP-UM | Population in upper middle income group | at residence |
| POP-LM | Population in lower middle income group | at residence |
| POP-LO | Population in low income group | at residence |
| EMP-HI | Employed population of high income group | at residence |
| EMP-UM | Employed population of upper middle income group | at residence |
| EMP-LM | Employed population of lower middle income group | at residence |
| EMP-LO | Employed population of low income group | at residence |

| Shopping | | TPSHOP | POP * 0.1387-832 |
| To Home | | TPHOME | DAY POP * 0.9983-7483 |

Table 7.2.6 Trip Attraction Model

| Trip Purpose | Income Group | Trip Production | Formula |
|--------------|--------------|-----------------|--|
| To Work | High | TPW HI | EMP HI * 0.9245 |
| | U. Middle | TPW UM | EMP UM * 0.9304 |
| | L. Middle | TPW LM | EMP LM * 0.9053 |
| | Low | TPW LO | EMP LO * 0.8511 |
| To School | High | TPS HI | STU HI * 0.9350 |
| | U. Middle | TPS UM | STU UM * 0.9635 |
| | L. Middle | TPS LM | STU LM * 0.9844 |
| | Low | TPS LO | STU LO * 0.9854 |
| Business | | TTBUSI | JOBSEC * 0.1259 + JOBTER * 0.1189 961 |
| Private | | TPPRIV | DAY POP * 0.2260-2848 |
| Shopping | | TPSHOP | jobcom * 1.0858 + 2166POP * 0.1387-832 |
| To Home | | TPHOME | POP * 0.9244-2648 |

Number of jobs by income group is estimated based on number of jobs by industrial sector (5).

- Multiple regression equations for "to home", "business", "private matters", and "shopping" trips.

The zonal parameters estimated as the variables in the trip production and trip attraction models are shown in Table 7.2.4. The models are summarized in Table 7.2.5 and 7.2.6.

7.2.5 Trip Distribution Model

Trip distribution, that is, the technique by which trips generated by each zone (refer previous section) are linked with all other zones accessible via the roadway network, is accomplished with the use of gravity models. These reflect road network levels of service in the travel deterrence function, and are thus sensitive to changes in trip distribution patterns catalyzed by road system modifications and/or improvements.

The gravity models employed in this study are of the doubly-constrained type with the following formulation :

$$T_{ij} = \frac{P_i A_j F_{t,ij} K_{ij}}{\sum_{ij} P_i A_j F_{t,ij} K_{ij}}$$

- Where T_{ij} = Trips produced in zone i and attracted to zone j
 P_i = Trips produced in zone i
 A_j = Trips attracted to zone j
 $F_{t,ij}$ = Empirically derived travel factor for time t between zones i and j
 K_{ij} = Specific zone-zone (or province-province) adjustment factor to allow for the effect of travel linkages not otherwise explained by the gravity model.

This gravity model formulation constrains balancing of observed trips to modeled trips (as estimated by the trip generation model). Through this process the originally calibrated trip-end patterns are maintained.

Use of the travel deterrence function in this model (F-Factor curves) is preferred to the use of an exponential formulation since it is possible to manually adjust the calibrated F-Factors to more precisely fit the characteristics of the observed OD- data.

The gravity model was calibrated to the available 1985 ARSDS OD Matrix data (person trip, 12 purposes). Due to data incompleteness in some area in Botabek, only data of DKI area (90 zones) was used in the analysis. It is possible, however, to use the Calibrated Gravity Models to estimate trips in Botabek and between DKI-Botabek.

**FIG. 7.2.3
PERSON TRIP FLOWS
IN JAKARTA METROPOLITAN AREA
YEAR 1993**

Desire lines of the base year (1993) person trip in Jakarta Metropolitan Area is shown in Figure 7.2.3.

7.2.6 Modal Split Model

The structure of model is a binary choice model as depicted in Fig. 7.2.4.

The modal split model derived in the ARSDS is rather simple. Merely road distance and ratio of travel time are incorporated in the model.

(1) Non-motorized Transport/Motorized Transport Split Model

Percentage share of non-motorized mode of transport, varies according to distance by trip purpose and income level of trip makers as shown in Fig. 7.2.5.

(2) Public Transport/Private Transport Split Model

Percentage share of public transport depends on the ratio of travel time by public transport to private transport as shown in Fig. 7.2.6.

(3) Sedan/Motorcycle Split Model

After trips are split into public transport and private transport, trips made by private transport are further divided into trips by private passenger cars and by motorcycles according to trip length. Sedan/Motorcycle split curves are illustrated in Fig. 7.2.7.

After person trips are split into trips by mode of transport according to trip purpose and income level, the estimated trips by trip purpose are combined into all trip purposes. Furthermore, person trips made by private mode of transport are converted into vehicle trips by dividing average occupancies shown in Table 7.2.7. Moreover, these vehicle trips are further converted into P.C.U. (Passenger Car Unit) trip OD matrices by applying passenger car equivalent factors for traffic simulation analyses.

Table 7.2.7 Average Occupancy by Vehicle Type

| Area | Sedan | Motorcycle |
|---------------------|-------|------------|
| Within DKI Jakarta | 1.96 | 1.20 |
| DKI Jakarta-Botabek | 1.99 | 1.31 |

FEASIBILITY STUDY ON URBAN ARTERIAL ROAD SYSTEM DEVELOPMENT PROJECT IN JAKARTA METROPOLITAN AREA **FIG. 7.2.6** Public Transport/Private Transport Split Model

7.3 Base Year (1993) Calibration

The primary purpose of base year calibration is to get a reasonably sound base year (1993) OD Matrix that can be used as 'starting point' for subsequent traffic analysis.

7.3.1 Year 1993 Trip Generation

The Trip Generation Total for DKI Jakarta and Botabek is summarized in Table 7.3.1.

Table 7.3.1 Trip Generation of DKI Jakarta and Botabek, 1993

Unit: thousand person trips

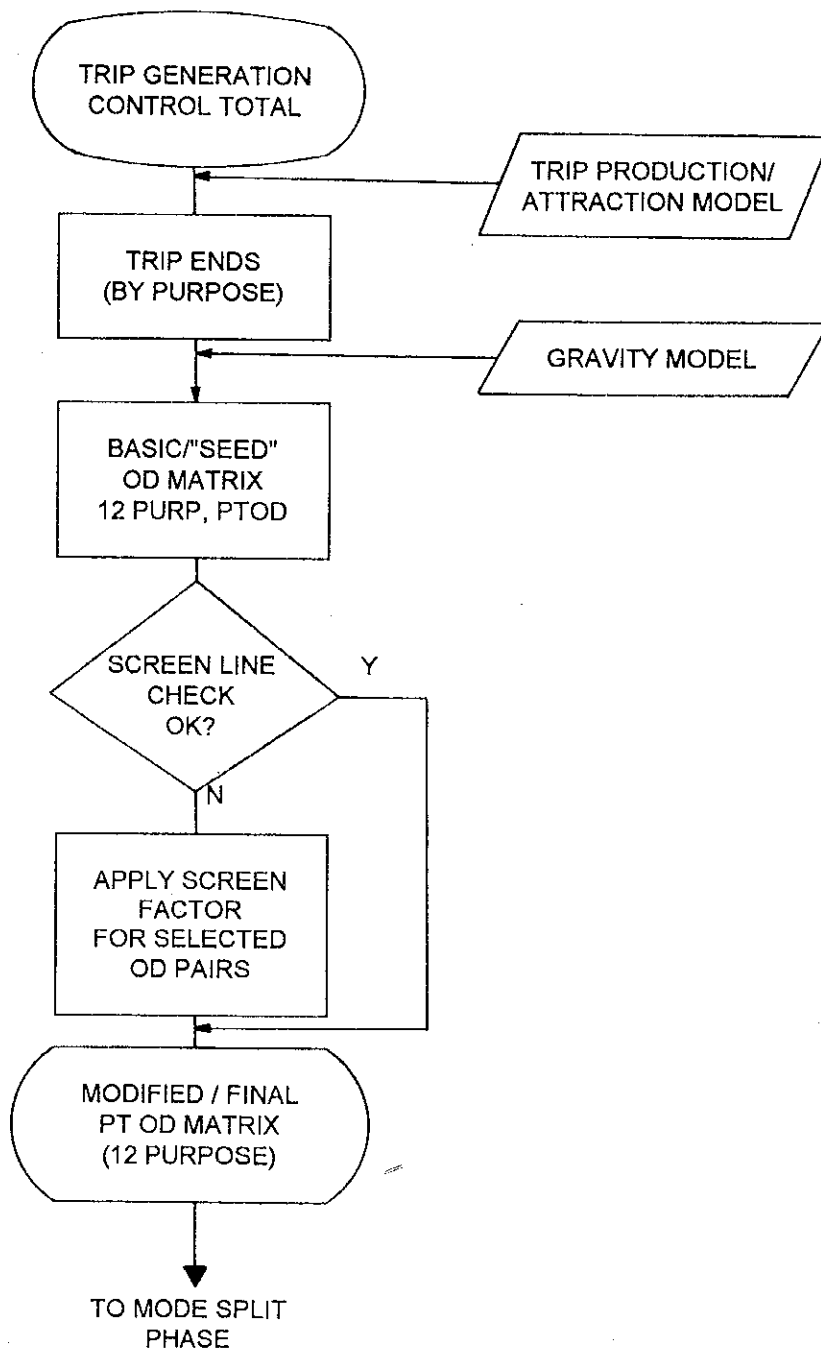

| Trip Purpose | Income Level | DKI Jakarta | Botabek |
|--------------|--------------|-------------|---------|
| To Work | High | 263 | 38 |
| | U. Middle | 620 | 368 |
| | L. Middle | 1,278 | 1,167 |
| | Low | 1,231 | 1,847 |
| | Sub-total | 3,392 | 3,420 |
| To School | High | 155 | 22 |
| | U. Middle | 397 | 236 |
| | L. Middle | 853 | 778 |
| | Low | 688 | 1,032 |
| | Sub-total | 2,092 | 2,068 |
| To Home | All | 7,270 | 7,213 |
| Business | All | 774 | 734 |
| Private | All | 1,819 | 1,618 |
| Shopping | All | 1,086 | 1,121 |
| Total | | 16,435 | 16,175 |

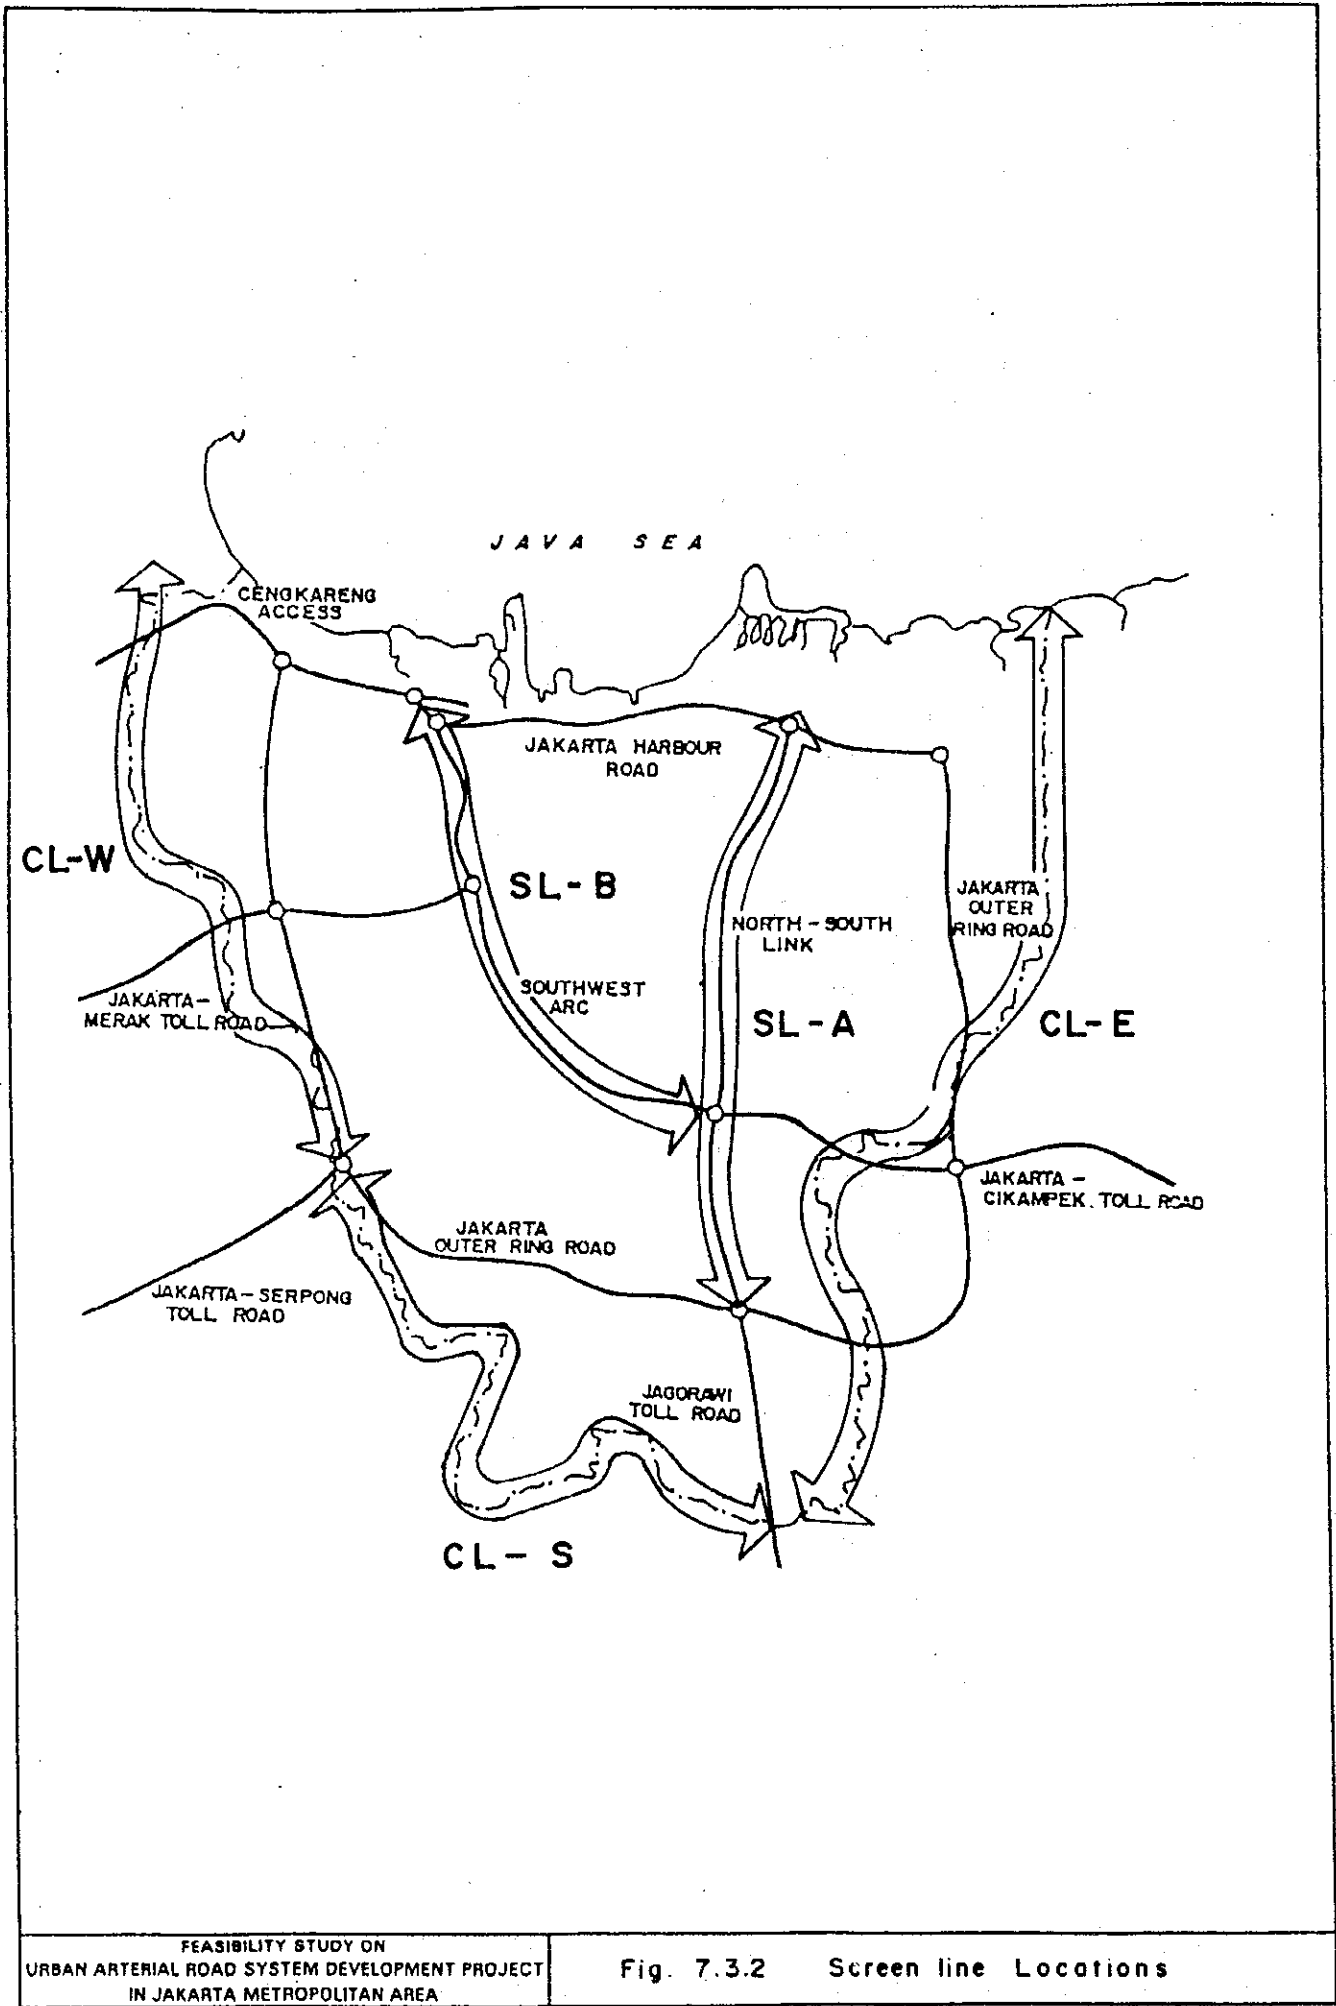

Constrained by this trip generation, trip production and attraction of each zone can then be estimated using the relationships set forth in Section 3.1.1.

7.3.2 Year 1993 OD Matrix Development and Calibration

First of all, the 1993 inter-zonal OD Matrix was estimated by utilizing the Gravity Model. Intra trips were calculated externally using the relationship employed during 1985 Gravity Model Calibration. These trips were then combined to make a basic 1993 OD Matrix (by trip purpose) for subsequent calibration.

To judge the goodness of the OD matrix in replicating the existing trip-making characteristics, a series of screen lines and cordon lines were determined to check traffic volumes on these crossings. Figure 7.3.1 illustrates the work flow

FEASIBILITY STUDY ON
 URBAN ARTERIAL ROAD SYSTEM DEVELOPMENT PROJECT
 IN JAKARTA METROPOLITAN AREA

Fig. 7.3.2 Screen line Locations

of Person Trip OD Matrix calibration, and Figure 7.3.2 shows the screen line locations.

A preliminary traffic assignment (person trip based) was performed and the result is summarized in Table 7.3.2.

Table 7.3.2 Screen Line Comparison (before adjustment)

| Screen Line | Traffic Count (Conv. to person) | | | | Assignment | Ratio Asg/TC |
|-------------|---------------------------------|-----------|------------|-----------|------------|-----------------|
| | MC | Sed | Publ (Bus) | Total | | |
| SL-A | 170,443 | 663,432 | 1,055,593 | 1,889,468 | 1,764,896 | 0.93 |
| SL-B | 426,926 | 1,561,170 | 1,566,954 | 3,555,049 | 2,651,691 | 0.75 |
| CL-W | 82,617 | 253,244 | 378,057 | 713,918 | 528,828 | 0.74 |
| CL-S | 73,463 | 282,616 | 604,154 | 960,233 | 1,133,342 | 1.18 |
| CL-E | 68,461 | 225,906 | 526,130 | 820,497 | 793,901 | 0.97 |

Traffic volumes on Screenline-B, Cordon line W and S are significantly different from the actual condition. Accordingly, adjustment factors were applied only for those trips crossing screen line CL-S, and combination of screen line CL-W and SL-B.

Calibration result in the form of block OD is shown in Table 7.3.3. Average trip length by trip purpose was also calculated and summarized in Table 7.3.4.

7.3.3 Modal Split & Conversion to Vehicle OD Matrices

The modal share of person trips by both motorized and non-motorized mode of transport were estimated by using the modal split model described in the previous section.

In order to calculate Vehicle Trip OD Matrix, the following vehicle occupancy rate was used.

| Mode | Area | |
|-------|------------|-------------|
| | Within DKI | DKI-Botabek |
| MC | 1.20 | 1.31 |
| Sedan | 1.96 | 1.99 |
| Bus* | 18.9 | 16.8 |

* based on 1993 survey data.

Vehicle OD Matrices, as converted from Person OD Matrices, are only available for Motorcycle, sedan and bus. No Vehicle OD Matrix for Truck can be estimated from Person OD Matrix. To 'fill-in' this gap, Truck vehicle OD

7.4 Future Traffic Demand Forecast

Future demand forecasting was conducted based on an assumption that the base year calibrated mathematical relationships which represent trip-making characteristics are applicable for the whole planning year. The forecasting process and some findings are summarized in the following section. Year 2010, the ultimate year, was of a focal point in which Person and Vehicular Trip Matrices were thoroughly estimated. The figures for year 2000 were conveniently interpolated from the 1993 and 2010 matrices.

7.4.1 Future Trip Generation

Trip Generation in both DKI Jakarta and Botabek for the year 2010 was estimated and listed in Table 7.4.1. The person travel demand was then broken down into analysis zone using trip production and attraction models described in Section 7.2.3. Trip production in suburban area generally grow more rapidly in future years due to expansion of urbanized area.

Table 7.4.1 Estimated Trip Generation in DKI Jakarta and Botabek, 2010

Unit : Thousand person trips

| Trip Purpose | Income Level | DKI Jakarta | Botabek |
|--------------|--------------|---------------|---------------|

7.4.2 Year 2010 Person Trip OD Matrices

The 2010 inter-zonal person trip OD matrices were developed using the Gravity Model. Intra trips, as per current procedure, were calculated externally and later combined with inter-zonal trips. The resulting person trip OD matrices, in the form of "block OD", is shown in Table 7.4.2. Compared

with 1993 person trip flows, a significant increase of travel demand would appear in suburban areas. Trips produced and attracted from/to the Central area will also increase due to intense utilization of land in the area. Thus, increase of trip length in addition to increase in number of trips would become heavy burden on transportation network in the study area.

Desire lines of the 2010 person trips in Jakarta Metropolitan Area is shown in Figure 7.3.3.

7.4.3 Modal Split and Conversion to Vehicle OD Matrices

Modal split analysis was done based on modal split model described in the previous section.

Number of person trips by mode of transport projected by the modal split model is shown in Table 7.4.3. This modal share would vary depending on the transportation policy such as a traffic demand constraint policy in CBD.

Following conversion from person trip OD matrices to vehicle OD matrices, the sedan, motorcycle and bus matrices were developed. Again, truck OD matrix was adopted from ORR-WI study.

During the traffic simulation process, it was deemed necessary to further modify the vehicle OD matrices to achieve a technically reasonable traffic spread throughout the network.

The method adopted is explained below :

- The 2010 vehicle OD matrices developed from person OD matrices was used as 'constraint', in which the trip ends were regarded as control total.
- The 1993 vehicle OD matrices were factored-up to 2010 by a Fratar technique. By this procedure, which is available as a function of TRANPLAN, each trip interchange between zones are iteratively expanded and/or adjusted until the row and column totals replicate the indicated control total.

7.4.4 Future Highway and Transit Network

The transportation network in the transportation analysis is classified into two types of network; highway network and transit network. Highway network consists of arterial road network and tollway system.

In the traffic simulation analysis, the Jakarta-West Java tollway system, which consists of the Intraurban Tollway System, the Outer Ring Road, and Regional Tollway, is assumed to be completed by the year 2000. Arterial road network for future years was coded based on the road development plan in DKI Jakarta,

taking the recent progress of road development conducted by the local government into account. The project roads were added on this base road network in 2000 and 2010.

On the other hand, the transit network consists of bus network and railway network, that is, heavy rail network for the current year and new light rail network for the future years. The development schedule of mass rapid transit system follows the on-going study by the inter-department group.

Traffic simulation was executed based on these highway and transit networks.

7.4.5 Future Trip Assignment

Assignment of the respective 2000 and 2010 forecast vehicle (in passenger car unit, pcu) OD matrices was carried out in two batches :

- Batch 1
First of all, non-tollway vehicles (i.e. motorcycle) were loaded onto arterial roads and exempting them from using the tollway. Assignment were performed in an incremental basis where the network impedance is subsequently adjusted, iteration by iteration, according to the specified capacity restraint function.
- Batch 2
With the non-tollway vehicles already in the network, other modes were loaded onto both arterial and tollway roads. Assignment were performed using the "equilibrium technique". Equilibrium assignment consists of an iterative series of all-or-nothing traffic assignments with an adjustment of travel times reflecting delays encountered in the associated iterations which is done until no trip can be made by an alternate path without increasing the total travel time of all trips in the network.

Traffic assignments were carried out for several cases including :

- The base case; only committed network improvement, without NS axis tollway nor EW axis road
- With NS axis tollway only
- With EW axis only
- With both NS axis tollway and EW axis road.

Outputs from these assignments (especially those for the year 2010) were used to analyze, among others :

- identification of interchange locations
- profile of tollroad users
- preparation of traffic management measures in congested area
- design of interchanges

The year 2010 traffic volume snapshots on NS axis tollway and EW axis road are presented in Figure 7.4.1 and 7.4.2 respectively. With reference to Figure 7.4.3, the traffic volume incidence in major locations are summarized in Table 7.4.4.

Table 7.4.4 Forecasted Link Load in Year 2010 By Cases of 'Without N-S Axis nor E-W Axis', 'With Only N-S Axis' and N-S Axis and E-W Axis'

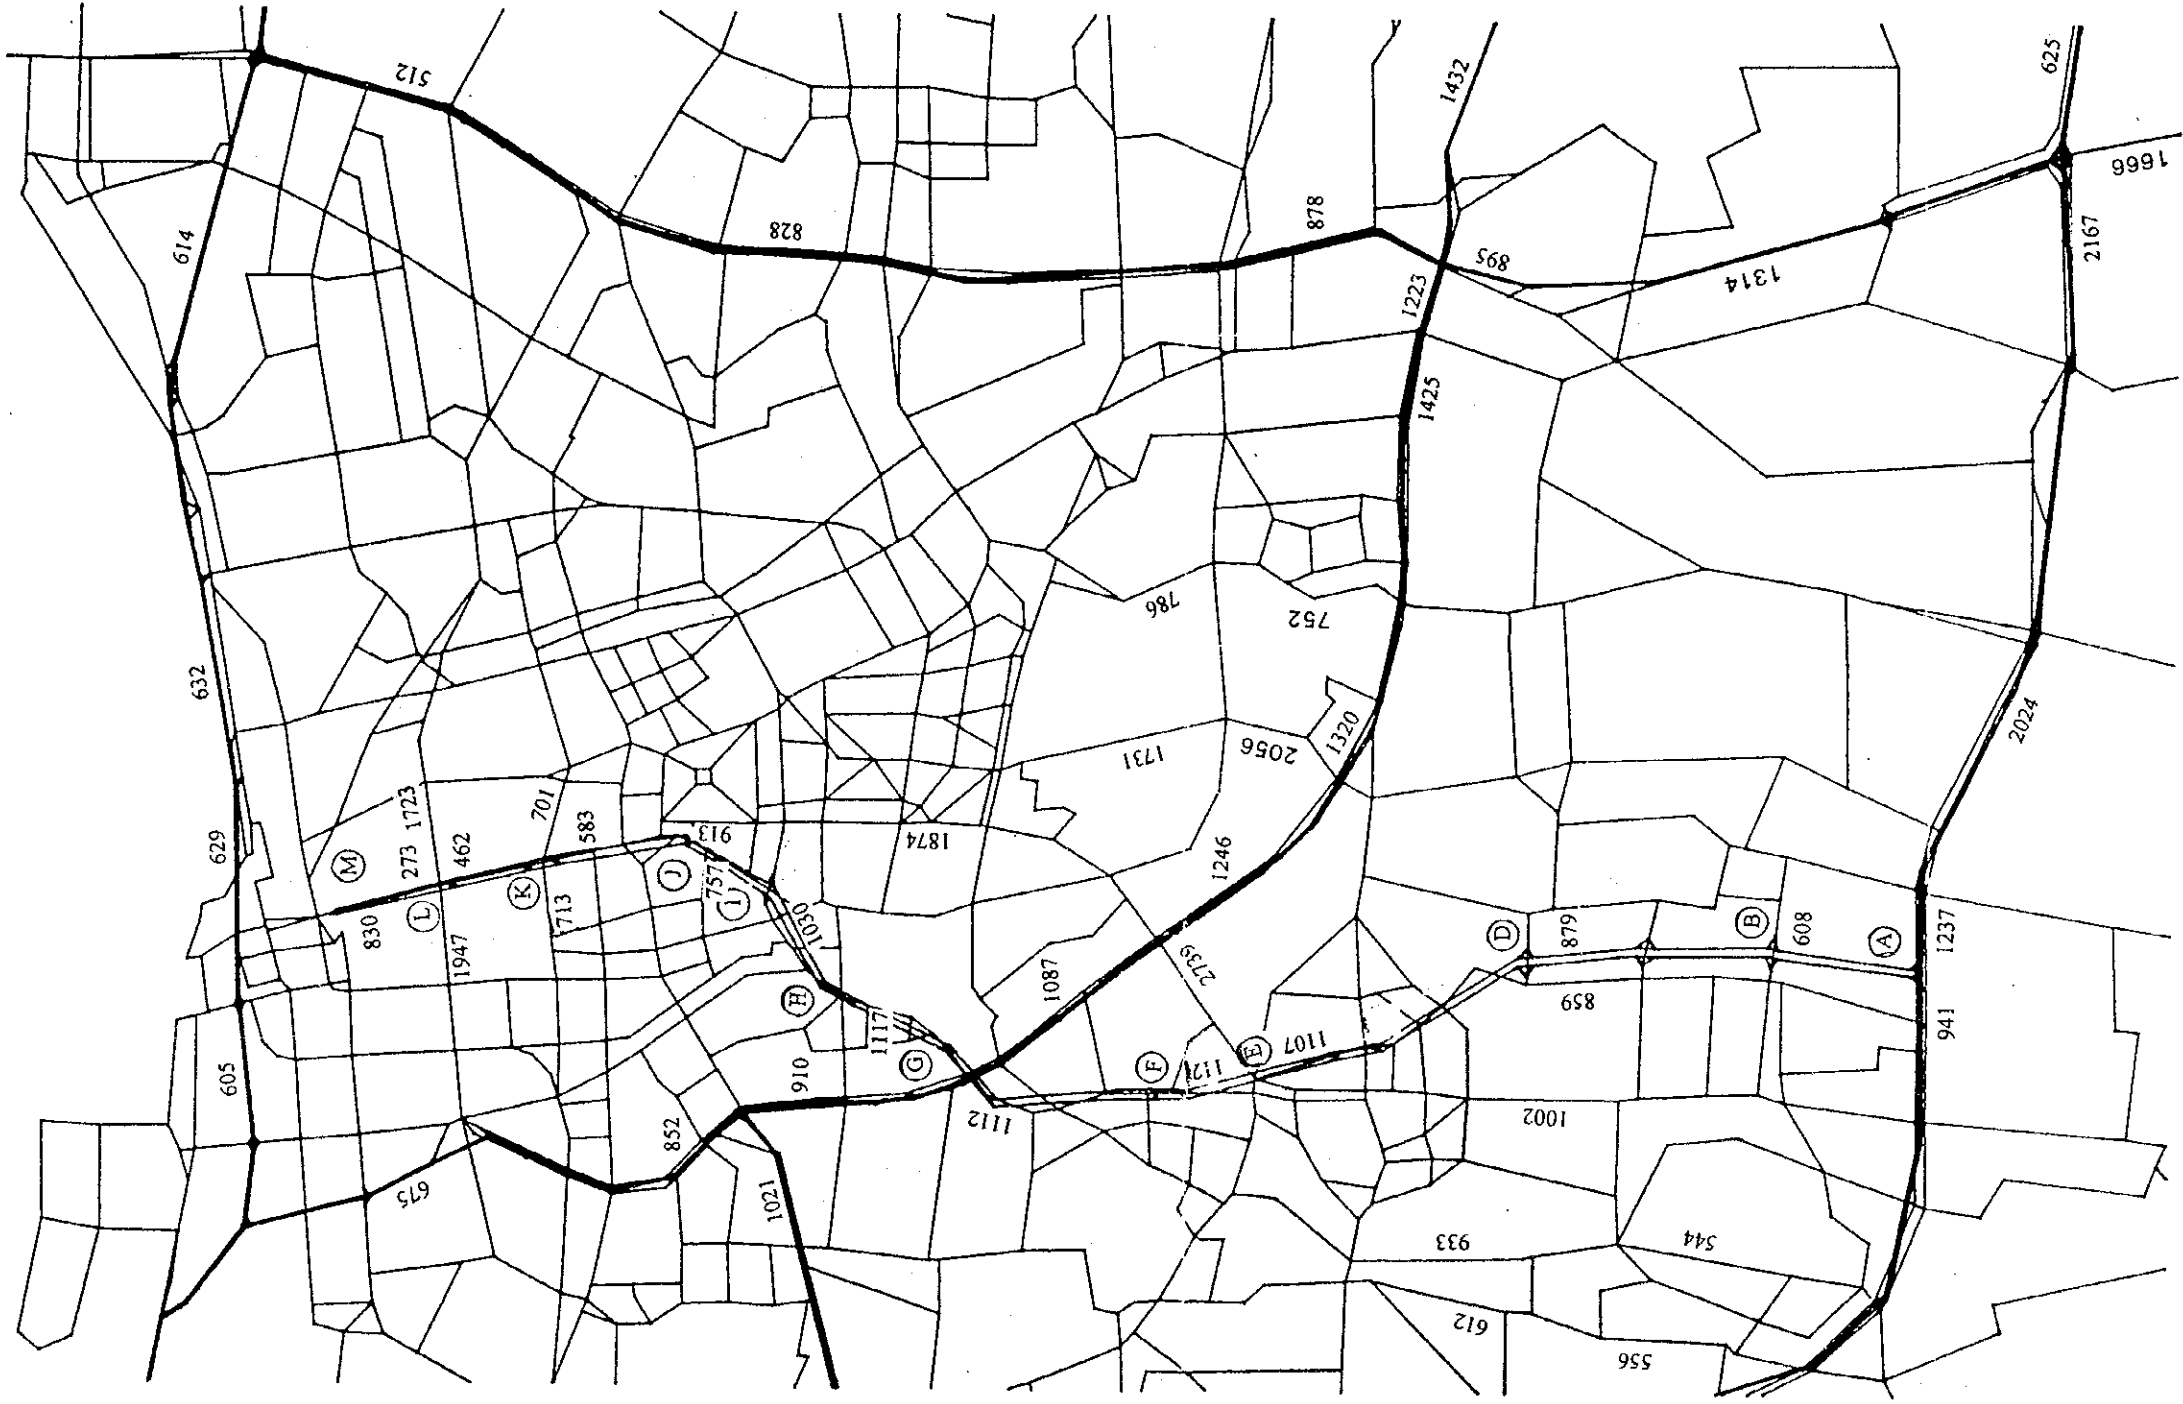

(UNIT : PCU/DAY)

| No | Road Section | YEAR 2010 | | | Present Traffic Volume Counted |
|-----|---|----------------------|----------------------|---------------------|--------------------------------|
| | | Without Project | N-S Axis Only | N-S & E-W Axes | |
| 1. | Northern Location at Jl. Gajah Mada / Hayam Wuruk | 91,300 (91,300) | 112,000 (83,000) | 117,000 (83,000) | 117,251 |
| 2. | Southern location at Jl. Gajah Mada/Hayam Wuruk | 106,000 (106,000) | 146,000 (106,000) | 155,000 (97,000) | 118,303 |
| 3. | Jl. Kyai Tapa | 95,500 | 86,500 | 96,500 | 106,586 |
| 4. | Jl. Tomang Raya | 115,000 | 111,000 | 105,000 | |
| 5. | Jl. Pangeran Tubagus Angke | 91,400 | 85,700 | 83,400 | 35,929 |
| 6. | Jl. Moch. Mansyur | 90,800 | 88,900 | 87,000 | |
| 7. | Jl. Mangga Dua | 121,100 | 126,400 | 113,800 | 39,721 |
| 8. | Jl. Gunung Sahari | 106,900 | 100,800 | 94,900 | 68,257 |
| 9. | Jl. Jembatan Tiga | 94,500 | 95,900 | 99,800 | 88,763 |
| 10. | Jl. Mangga Besar | 81,800 | 88,800 | 172,300 | 43,621 |
| 11. | Mangga Besar Extension | 98,500 | 98,600 | 194,700 | -- |
| 12. | Jl. Bandengan | 54,400 | 57,600 | 46,100 | 46,666 |
| 13. | Jl. Medan Merdeka Barat | 105,600 | 88,200 | 91,300 | |
| 14. | Jl. M.H. Thamrin | 184,500 | 183,700 | 187,400 | 171,307 |
| 15. | Jl. Kebon Sirih | 98,300 | 91,200 | 82,500 | |
| 16. | Jl. Sudirman | 300,400 | 281,200 | 273,900 | 185,513 |

| No | Road Section | YEAR 2010 | | | Present Traffic Volume Counted |
|-----|---|----------------------|---------------------|---------------------|--------------------------------|
| | | Without Project | N-S Axis Only | N-S & E-W Axes | |
| 17. | Jl. Daan Mogot | 134,000 | 136,500 | 129,000 | |
| 18. | Jakarta - Tangerang Tollway | 151,000 | 146,000 | 112,000 | |
| 19. | Jl. Hang Tuah and Jl. Sisingamangaraja | 125,300 78,800 | 113,800 70,300 | 115,000 74,400 | |
| 20. | Jl. Pangeran Antasari | 100,000 (100,000) | 163,300 (78,300) | 161,700 (73,700) | 54,450 |
| 21. | Jl. Buncit Raya | 95,000 | 88,400 | 89,300 | (44,207) |
| 22. | Jl. Pasar Minggu Raya | 105,500 | 98,400 | 96,700 | |
| 23. | Jl. Buncit Raya | 123,100 | 112,100 | 110,400 | |
| 24. | Jl. Pasar Minggu Raya | 128,500 | 122,400 | 124,400 | |
| 25. | Jl. H.R. Rasuna Said | 205,200 | 181,800 | 179,100 | 89,291 |
| 26. | Jl. Dr. Saharjo | 85,200 | 82,100 | 78,600 | 51,680 |
| 27. | Jl. Tambak | 68,000 | 69,100 | 69,500 | |
| 28. | Jl. Diponegoro | 78,700 | 81,500 | 74,900 | |
| 29. | Jl. Pasar Senen | 71,300 | 70,300 | 67,600 | |
| 30. | Jl. Utan Panjang | 73,700 | 69,100 | 66,800 | |
| 31. | Jl. Landasan Utara/Selatan | 73,100 | 72,800 | 57,200 | |
| 32. | Jl. Gunung Sahari | 120,600 | 114,400 | 98,600 | |
| 33. | Jl. Landasan Utara/Selatan | 37,400 | 36,000 | 28,400 | |

Note : 1. For cases with the project, the figures in the parenthesis show the link load on the arterial road at the location.

2. Present traffic volumes, excluding the number of motorcycles were counted in December 1992, June 1993 or December 1993.

Fig. 7.4.3 LOCATION OF ROAD SECTION FOR FORECASTED LINK LOAD

The following paragraphs summarize the main findings from the traffic assignment cases.

1) Trip Characteristics

a) North-South Axis

Comparison was made between the trips using North-South Axis (Tollway) and those using the arterial road (Jl. Sudirman)

The average trip lengths of North-South Axis users are 70% longer for passenger car and bus, 20% longer for truck than those of the paralleled arterial road users. This leads that the project tollway is rather functionable to divert the longer trip traffic or the semi regional traffic from the present arterial roads such as Jl. Thamrin and Jl. Sudirman to the proposed North-South Axis Tollway (see Table 7.4.5).

Table 7.4.5 Comparison of Average Trip Length between Jl. Sudirman and N-S Axis

| Type of Vehicle | Jl. Sudirman | | | N.S. Axis | | |
|-----------------------|--------------------|-------------------------|--------------------------|--------------------|-------------------------|--------------------------|
| | Link No. Node-Node | Traffic Volume (P.C.U.) | Average Trip Length (Km) | Link No. Node-Node | Traffic Volume (P.C.U.) | Average Trip Length (Km) |
| Private Passenger Car | 2065-2070 | 98,336 | 12.5 | 8060-8066 | 41,944 | 21.2 |
| | 2070-2065 | 95,520 | 12.6 | 8065-8061 | 45,579 | 21.6 |
| | Total | 193,856 | | Total | | |
| Truck | 2065-2070 | 5,899 | 19.4 | 8060-8066 | 3,740 | 23.9 |
| | 2070-2065 | 6,057 | 20.6 | 8065-8061 | 3,886 | 25.0 |
| | Total | 11,956 | | Total | | |
| Bus | 2065-2070 | 17,828 | 12.7 | 8060-8066 | 7,690 | 21.3 |
| | 2070-2065 | 17,389 | 12.8 | 8065-8061 | 8,359 | 21.7 |
| | Total | 35,217 | | Total | | |

b) East-West Axis

The comparison of the proposed East-West Axis and parallel arterial roads in the western area, the central area and the eastern area shows the following characteristics (see Table 7.4.6).

- Road users in the western area of Jakarta do not show a remarkable difference in trip length for the proposed road and pertaining arterial roads (Jl. Daan Mogot and Planned DKI road)

Table 7.4.6 (1) Comparison of Average Trip Length between East-West Axis, DKI Road along Tangerang Line, and Jl. Daan Mogot

| Type of Vehicle | East-West Axis | | | Planned DKI Road | | | Jl. Daan Mogot | | |

Table 7.4.6 (3) Comparison of Average Trip Length between East-West Axis and Jl. Perintis Kemerdekaan

| Type of Vehicle | East-West Axis | | | Jl. Perintis Kemerdekaan | | |
|-----------------------|--------------------|-------------------------|--------------------------|--------------------------|-------------------------|--------------------------|
| | Link No. Node-Node | Traffic Volume (P.C.U.) | Average Trip Length (km) | Link No. Node-Node | Traffic Volume (P.C.U.) | Average Trip Length (km) |
| Private Passenger Car | 3745-6080 | 52,542 | 19.1 | 3760-6100 | 58,089 | 13.7 |
| | 6080-3745 | 51,374 | 16.4 | 6100-3760 | 50,574 | 16.6 |
| | Total | 103,916 | | Total | 108,663 | |
| Truck | 3745-6080 | 9,587 | 34.7 | 3760-6100 | 5,912 | 34.2 |
| | 6080-3745 | 7,482 | 33.1 | 6100-3760 | 7,171 | 32.2 |
| | Total | 17,069 | | Total | 13,083 | |
| Bus | 3745-6080 | 9,687 | 19.3 | 3760-6100 | 11,357 | 13.5 |
| | 6080-3745 | 9,742 | 16.3 | 6100-3760 | 14,103 | 16.7 |
| | Total | 19,429 | | Total | 25,460 | |
| Motor Cycle | 3745-6080 | 4,581 | 19.4 | 3760-6100 | 9,801 | 13.5 |
| | 6080-3745 | 6,187 | 15.6 | 6100-3760 | 6,974 | 16.5 |
| | Total | 10,768 | | Total | 16,775 | |

- Road users in the central area and the eastern area show 30% to 50% longer trips for the proposed East-West Axis, when compared with Jl. Perintis Kemerdekaan and Jl. Sukarjo.
- Truck trips show relatively longer average trip length than other vehicle types.

c) Traffic Management at Kota area

It is predicted that excessively concentrated traffic would take place at the terminus of the North-South Axis in Kota area without any traffic management scheme. Considering present circumstances along Jl. Gajah Mada/Hayam Wuruk, it is rather hard to increase traffic capacity of Jl. Gajah Mada/Hayam Wuruk and its northern extension. Simultaneously, it is unlikely practical to cope with this kind of matter by means of increasing traffic capacity of a few major arterial roads to disperse such concentrated traffic.

On the other hand considerable traffic demand exists in Kota area, particularly built-up eastern block (see Fig. 7.4.4). However, the western block encompassed by Jl. Jembatan Dua and Jl. Pangeran Tubagus Angke will generate and attract enormous traffic in the future, according to the framework in Jakarta 2005. Such big traffic demand surely require well-planned transportation network, in particular functionally classified road network.

Present condition in the western block is designated as poor living environment and to be redeveloped as urban betterment with the first priority.

Accordingly, the concept of traffic management in Kota area is delineated in Fig. 7.4.5.

It is sure that the role and function of the East-West Axis will be enhanced considerably in case of the provision of semi-direct ramps with Jl. Gunung Sahari in the east and Jl. Jembatan Dua in the west as shown in Fig. 7.4.5. It will enable to disperse heavy traffic in Kota by means of circulation in periphery and to avert concentrated traffic load on Jl. Pintu Besar Selatan.

It is one of practical countermeasures that a depressed road which is continuously walled will be constructed on Jl. Pintu Besar Selatan/Utara to connect with Jl. Pakin in the northern block in case that DKI Jakarta intends to penetrate built-up area in the northern part of Kota, preserving present landscape in Kota area comprised by historical and monumental buildings. However, due to low ground water level in Kota area, the underpass structure will require mechanical drain by power pump in a depressed road section.

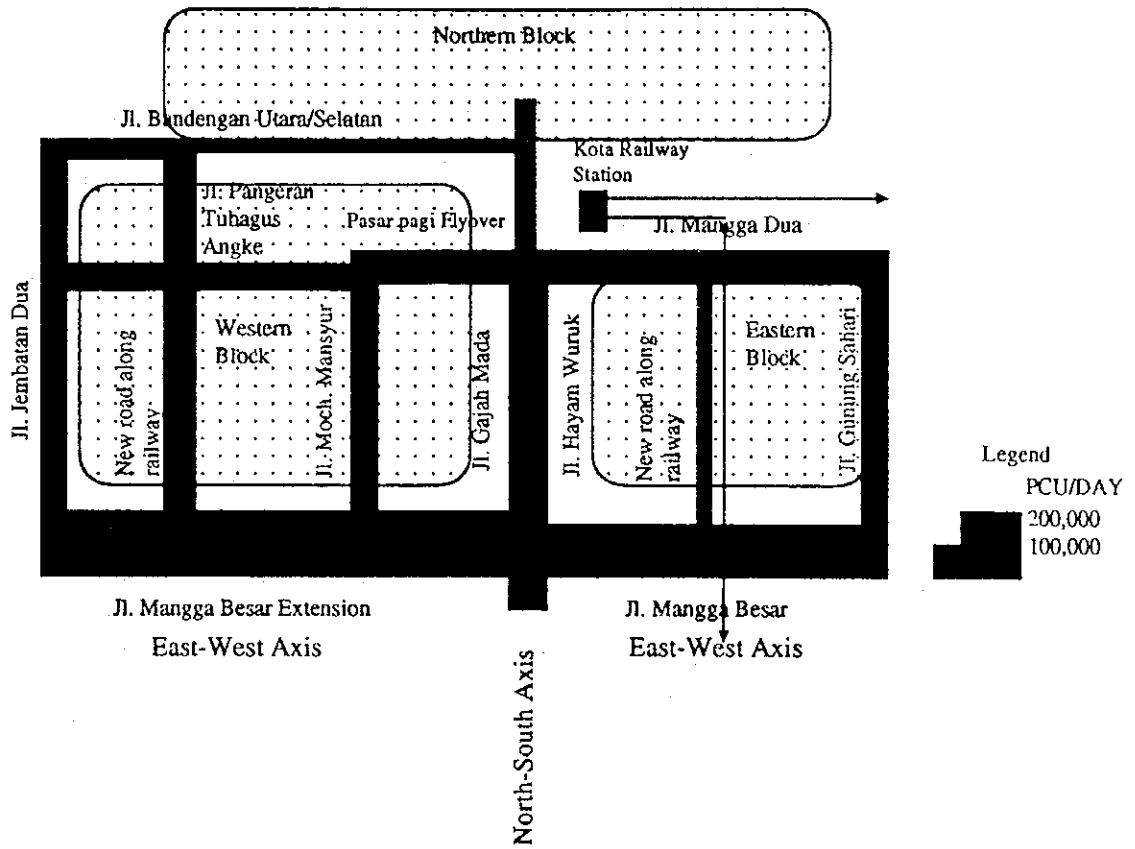

Fig. 7.4.4 TRAFFIC DEMAND FORECAST (YEAR 2010)

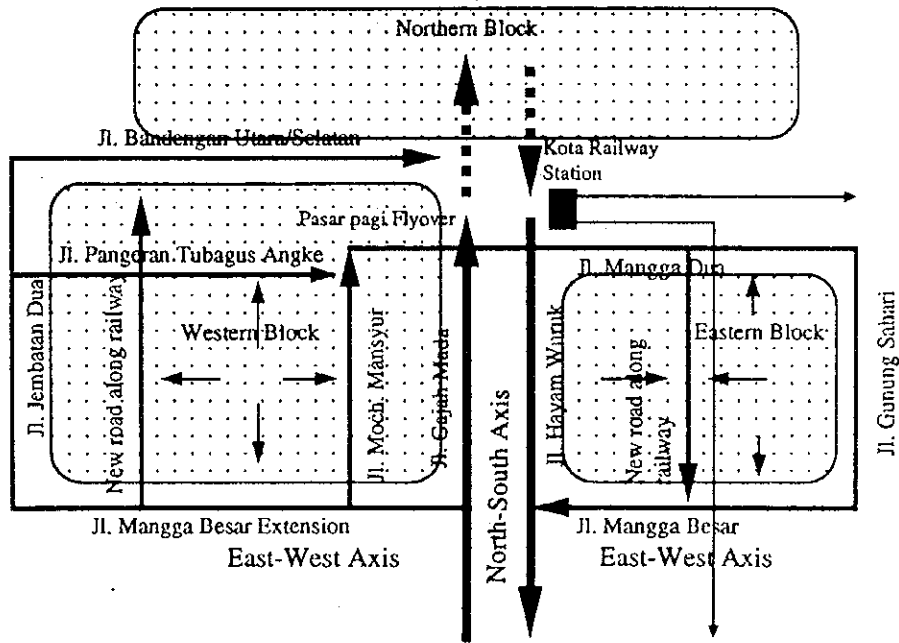

Fig. 7.4.5 CONCEPT OF TRAFFIC MANAGEMENT IN KOTA

2) Tollroad Users

The tollway users for Year 2000 and Year 2010 by toll rate are shown in Table 7.4.7.

The uses are 60,000 PCU/day to 75,000 PCU/day in Year 2000 for toll rates of Rp.5,000 per PCU trip and Rp.2,000 per PCU trip respectively (The toll rate is at 1994 price).

In Year 2010 those are estimated 90,000 PCU/day to 115,000 PCU/day.

Table 7.4.7 Number of Users per Day for North-South Axis (Tollway)

YEAR 2000

| Toll Tariff (Gol. I) | Number of Trips (PCU/day) | Average Cross- Sectional Volume (PCU/day) | Average Trip Length on the Tollway (Km/trip) |
|---------------------------|------------------------------|---|--|
| Rp.2,000 per trip | 75,100 | 44,600 | 11.9 |
| Rp.3,000 per trip | 66,600 | 40,700 | 12.2 |
| Rp.4,000 per trip | 63,000 | 39,300 | 12.5 |
| Rp.5,000 per trip | 58,100 | 38,100 | 13.1 |

YEAR 2010

| Toll Tariff (Gol. I) | Number of Trips (PCU/day) | Average Cross- Sectional Volume (PCU/day) | Average Trip Length on the Tollway (Km/trip) |
|---------------------------|------------------------------|---|--|
| Rp.2,000 per trip | 114,800 | 70,000 | 12.2 |
| Rp.3,000 per trip | 107,200 | 66,500 | 12.4 |
| Rp.4,000 per trip | 100,300 | 64,000 | 12.8 |
| Rp.5,000 per trip | 90,400 | 62,000 | 13.7 |

3) Traffic Volume at Interchange and Intersections

In a more detailed fashion, traffic volumes on the on-and off-ramps of the NS axis tollway interchanges are shown in Appendix 7A for the Year 2010 and 2000. Summary of those volumes are presented in Table 7.4.8.

The traffic movements on major intersections of EW axis road for the Year 2010 are also shown in Appendix 7A.

Table 7.4.8 Interchange Volumes on NS Tollway

| Interchane Name | Interchange Volume (pcu/day) | | | |
|--------------------|------------------------------|----------------|---------------|---------------|
| | Year 2010 | | Year 2000 | |
| | On Ramp | Off Ramp | On Ramp | Off Ramp |
| South JORR | 31,700 | 29,100 | 20,400 | 22,500 |
| Pangeran Antasari | 17,200 | 9,800 | 12,400 | 8,500 |
| Kemang Raya | 8,500 | 14,300 | 4,800 | 6,300 |
| Senayan North | 1,600 | 1,700 | 500 | 500 |
| Senayan South | 1,600 | 1,300 | 600 | 400 |

| Mangga Besar | 9,300 | 9,500 | 7,300 | 7,800 |
| Glodok | 13,500 | 13,800 | 11,500 | 11,400 |
| Total | 114,800 | 114,800 | 75,100 | 75,100 |

4) Modal Split Results with LRT in North-South Axis Corridor

One of the outputs of the assignment shows rather preferable result for the public transport demand in this North-South Axis corridor.

This would resultantly lead that both the mass rapid transit development and the arterial road development strengthening this corridor are definitely required with parallel development as not only one development but both being developed simultaneously.

The results are shown in the following Tables 7.4.9 and 7.4.10.

Table 7.4.9 Modal Split of Transport Demand in North-South Corridor

Unit : Thousand Passenger/Day
() : Percentage

Year 2010

| | Grand Total | Public Transport | | | Private Vehicle | | |

CHAPTER 8 BASIC ROAD DEVELOPMENT PLAN FORMULATION

CHAPTER 8 BASIC ROAD DEVELOPMENT PLAN FORMULATION

8.1 Basic Arterial Road System

(1) Development Concept

In order to establish a basic arterial road system in Jabotabek, a principal development frame will be provided within the Jabotabek regional master plan and the Jakarta Structure Plan. The project roads are placed in the basic arterial road system and their roles and functions are defined in this system formation shown in Fig. 8.1.1.

As the result of reviewing the development scenarios and strategies for the Jabotabek Development Plan and the Jakarta Structure Plan, metropolitan development goals can be summarized as follows :

Jabotabek Development Context

- a) From the regional development concept of West Java Province, Jabotabek is located strategically important location, where primary connections are required in the regional and national development contaxes, to be more in quantity and heavier in quality as shown in Fig. 8.1.1.
- b) The Jabotabek Metropolitan Area should be formed adopting the East-West linear city model for the long-term perspective.
- c) The east-west axis and urban fringe areas are basically developed in the early stage by the intensification of present landuse, and the resulting urban concentration will extend about 50 km from east to west, 40 km from north to south, where the development should, however, be directed with priority to confined areas of development consolidation.
- d) The linear city concept is spined with a ladder type road structure (based on parallel arterial routes interspersed with cross-link) and there would be less traffic pressure on the urban core area (Jakarta). The ladder road structure will enhance potentials to foster urban centers/sub-centers at those node locations.
- e) The land use in the linear city concept is not a homogeneous belt of urban development but a balanced variable mixed use.
- f) It is imperative for the urban formation to establish a hierarchy of urban centers (which are categorized in the JMDPR by population size as shown in Fig. 4.1.7).
- g) The introduction of green space into the urban structure is essential to secure the future "quality of life" for the descending generation.

 URBAN ARTERIAL ROAD SYSTEM DEVELOPMENT PROJECT
 IN JAKARTA METROPOLITAN AREA

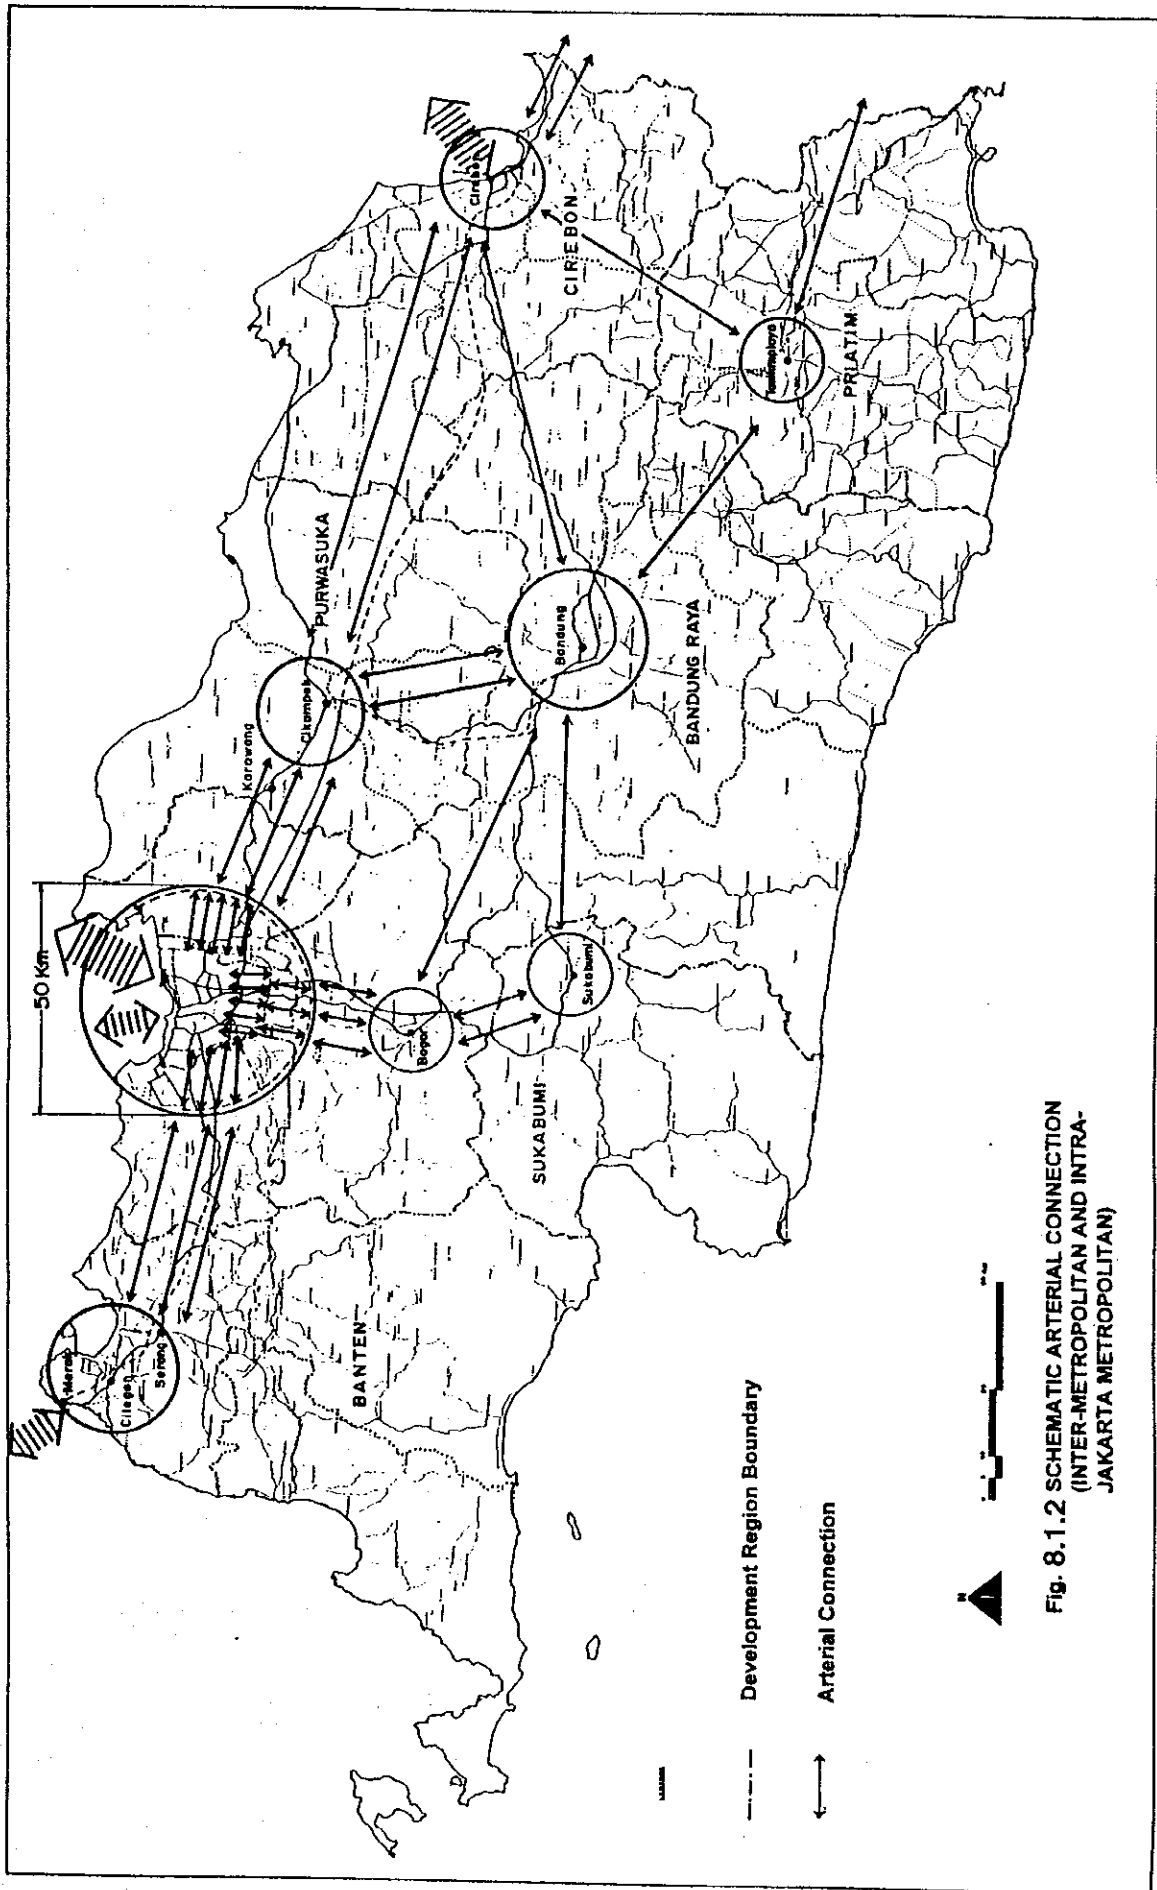

Fig. 8.1.2 SCHEMATIC ARTERIAL CONNECTION
(INTER-METROPOLITAN AND INTRA-
JAKARTA METROPOLITAN)

Jakarta Development Context

- a) Urban development priority should be given to the east-west direction, creating a new primary center development in the east and west.
- b) New development, especially in the Northwest and Northeast development regions should be limited at least until the year 2005. The south development region should be designated as the development control area to preserve natural environment and to eliminate as much as possible sources of water contamination for both surface and ground water.
- c) The intensity of development of activity centers (large and medium industry, trade center, service and offices) in the North and Central development regions should be limited, which should however be encouraged in the East and West development regions.
- d) Multi nucleus center development should be promoted with a proper center hierarchy to disperse the concentration of diversified activities into the central core area.

(2) Basic Arterial Road System Formation

1) Present Traffic Problem in Jakarta Metropolitan Area

Urbanization taken place in DKI Jakarta and its surrounding has naturally increased and continued toward the higher and upstream southern area from geographical reason. Road network in Jakarta Metropolitan area, which is the most fundamental infrastructure to constitute an urban structure, has been developed by several multi-lane arterial roads and its connecting roads. Ribbon development along major arterial roads, therefore, is dominant urbanization pattern. In order to keep mobility of major arterial roads, connecting roads have generally small capacity. Geographical features and urbanization pattern resulted in poor road network development in east-west direction.

On the other hand, public transportation fully depends on road transport. Although railway passengers for commuting are increasing gradually as commuter trains are introduced by official development aids from Japan and other foreign countries, the share of rail-base commuter remains only 3% and bus transport play important roles in public transport sector.

Rapid expansion of social and economic activities stimulates motorization in the urban area and resultingly chronic traffic congestion takes place on major arterial streets in the central business districts as well as on radial roads in the suburbs.

To cope with such traffic situation in Jakarta, the Government of Indonesia has decided to implement the various measures such as the expansion of one way traffic controlled area, increase of intersection with no right turning, application of exclusive bus lane and 3 in 1 regulation in the CBD as a short term scheme. However, it is impossible to solve traffic problems thoroughly by such traffic management scheme and social environment and living standard suffer damages by chronic traffic congestion.

2) Road Development Plans in Jakarta Metropolitan Area

In such circumstances, DKI Jakarta still retains the hub of financial, commercial and administrative activities in Indonesia and will continue to expand her urbanized area toward its surrounding, especially for east and west fringe of the city based on the development policy of Jabotabek Metropolitan.

The Government has medium and long term improvement plans in line with such development concept to construct toll roads and flyovers, to improve the existing railway for commuters and to introduce Light Rail Transit (LRT) system.

In order to propose the basic arterial road system in Jakarta Metropolitan Area, the following criteria/consideration is applied :

- a) Pressure and access requirements from further outside metropolitan areas to Jakarta Metropolitan Area.
 - Linkage from the secondary industry area to the tertiary and the administrative area v.v.,
 - Export and import purposes of products,
 - Governmental and social affairs,
- b) Most part of Kabupaten and Kotamadya Tangerang and Kabupaten and Kotif Bekasi are forming the Jakarta Metropolitan Area.
 - Free choice of jobs and almost no hazard for commuting and other activities,
 - Linkage of Botabek as the fringe area of DKI Jakarta,
- c) In order to synchronize those fringe area with main parts of DKI Jakarta.
 - Circular Arterial Roads including Jabotabek Ring Road
 - East-West Direction of Radial Arterial Roads, and
 - North-South Radial Arterial Roads should form arterial road system to meet both demand from outside of the metropolitan to the central area of DKI Jakarta and interval demand of the metropolitan.

In the central area, those radial roads would form a grid system road network with road hierarchy.

- d) But for the north-south direction radial arterial roads most of them should be limited inside the Jakarta Ring Road and a few radial arterial would be available to outside of the metropolitan area in order to guarantee the sustainable development in the southern region.
- e) Within DKI Jakarta, as the city planning road network including the improvement of intersection by flyovers or viaducts is planned and some of them are on-going or already programmed.

In order to realize the above mentioned arterial road network in the Metropolitan Area, at-most efforts should be taken to coordinate with such city planning road network and to make minimum modifications or additional works as those city planning road network has been worked out to meet the zoning plans.

- f) Mutual support with the mass rapid transit network are considered.
 - Supply easy access to the mass rapid transit network,
 - Better and easier operation and management of road traffic are possible with the well-balanced arterial road network,
 - Those better operation and management of road traffic would support higher user ratio of public transport including the MRT.
- g) In the central business district, the arterial road network is that of grid system with road hierarchy which would make it easier of urban unit development and of traffic management in the area.

Through those application and integrating the Metropolitan development strategies and targeted roles and functions of the project roads, a basic arterial road system was established separately for the Metropolitan area and for Jakarta's central urban area.

Metropolitan Area

- a) The east-west axis should be developed with a ladder type road structure with a proper planning of urban centers/sub-centers that could provide transport services with high efficiency.
- b) The ladder structure will initially be developed for about 50 kilometers in the east-west direction with about 10 kilometers in width along the belt.
- c) Introduction of mass transit system is essential to enable the urban area to expand \pm 50 km in the east-west direction.
- d) The east-west axis should be provided with multiple transport corridors to cope with diversified traffic characteristics from the mixed land use planned in the ladder road structure, the traffic demand will include such variation as long, medium and short distance; commuting, shopping, business, school purposes; and large/heavy cargo transport small parcel delivery.
- e) Southern Metropolitan area should be provided with some selected transport linkages to control spontaneous urban sprawls.
- f) The east-west axis outside the Jakarta Outer Ring Road should be planned as a divided carriageway with frontage facility road to secure the accessibility as well as mobility of the traffic in such developing areas as outside of the Ring Road.

Central Urban Area

- a) The road network planned in the Structure Plan 2005 should provide a basis to establish the basic arterial road system.
- b) As emphasized in the Structure Plan, the east-west axis development is a priority development policy, so that the axis should facilitate direct access to the CBD from either east or west centers, in order to stimulate these center developments.
- c) It is imperative to identify hierarchy of urban centers as well as street network to properly incorporate the project roads into the city planning road system.
- d) The east-west axis should be planned as the arterial road in order to improve the present network deficiency and to afford more efficient transport services. The access function of the east-west axis should depend on the adjacent land use and characteristics of traffic demand in different segment of the axis.
- e) The north-south axis should be prepared as a tollway to supplement the present Jl. Sudirman/Thamrin, and to eventually alleviate its traffic congestion.
- f) The north-south axis will function as an alternative route of the artery Jl. Sudirman/Thamrin, because the traffic demand in this direction is distinctively larger than others.

In accordance with the development concept, road development plan is formulated and implemented by DKI Jakarta and Directorate General of Highways, Ministry of Public Works.

3) Basic Arterial Road System Formation

The project roads are to work as one of links composed arterial road network system with designated roles and functions in Jakarta Metropolitan Area. The arterial road system is to provide mobility and accessibility for considerable traffic demand as a whole. The DKI Jakarta Structure Plan contains the road development masterplan which is officially approved in the study area, while the Jabotabek Metropolitan Development Plan Review (JMDPR) is prepared as the spatial plan to provide the development framework in the study area. The project roads which were proposed by ARSDS basically coincide with the location of city planning roads in the masterplan. However, recent road development and national economic growth stimulate regional economic activities and regional developments induce drastic change of massive demographic movement and commuters. It results in significant change of trip distribution. Accordingly, the review of roles and functions of each link including the project roads is required. The project roads are placed in the basic arterial road system and their roles and functions are defined in this system formation shown in Figs. 8.1.3 through 8.1.5 based on the above-mentioned review.

IN JAKARTA METROPOLITAN AREA**

8.2 Roles and Functions of Project Roads

8.2.1 East-West Corridor

A targeted role and function of the East-West corridor will be determined in such a development context of Jakarta Metropolitan Area and Jakarta itself.

1) Metropolitan Development Context

From the metropolitan development view, Tangerang and Bekasi are sub-growth centers, together with Depok, and are planned not only to accommodate housing facilities for Jakartans but also to support Jakarta's functions of such various sectors and levels as administrative, economic, social and cultural activities at national, regional and metropolitan levels.

In order to enable these cities to grow as sub-centers to Jakarta, the project corridor should provide higher mobility to stimulate the relocation of urban function from Jakarta, and concurrently raise their own development potentials.

A real estate development has been taking place rapidly in a last decade around the east and west urban fringe area. The population growth in these areas exceeds more than 7% p.a. during 1980-1990. Many of the increased population are Jakartans who have their jobs in Jakarta.

Despite such a dramatic population growth in the urban fringe area, transport facilities remain poorly developed. Accordingly, it is also requested that the East-West corridor should strengthen the road network in the Jakarta urban fringe area.

Thus, the East-West corridor should be planned to further enhance the development potentials of the two cities, and also to accommodate traffic service to newly developed residential areas of east and west periphery of DKI Jakarta.

2) Urban Development Context

In compliance with the development policy of Jabotabek, DKI Jakarta Structure Plan 2005 supports the urban development in the east-west direction, and it plans to develop new primary centers in the east and west as shown in the structure plan Fig. 4.2.2.

A road network in Jakarta has been developed in the north-south direction mainly because of Jakarta's geography. East-west connections, crossing rivers and major north-south arterial roads, are only developed for local traffic services with a relatively narrow width. A long thoroughfare such as Jl. Sudirman/Jl. Thamrin and Jl. Gunung Sahari - Jl. Otista is developed few, particularly in the area enclosed by Intra Urban Tollway.

Besides the center development in the east and west, a housing development in a large scale has been in progress to absorb relatively high income group of Jakarta residents. Local and service road networks are constructed in and around the planned new residential estate but they are concentrating to the existing east-west artery neither expanding the existing capacity nor constructing a new artery.

Therefore, from the urban development context, the East-West corridor should be planned so as to stimulate the development of planned east and west primary centers, to enhance the road capacity in the new housing development area, and to support through traffic in the central urban area.

This east-west axis should primarily play a role of the development inducement with additional and stronger access among several required access routes between Kabupaten/Kotamadya Tangerang and the central business district of DKI Jakarta; and between Kabupaten Bekasi and the central business district; and the port of DKI Jakarta in order to form the Jakarta Metropolitan Area.

Besides above, secondarily the axis take another role as a good arterial access to the central business district from those primary centres under development, e.g. East Primary Centre and from those large scale developments in surrounding area of those primary centers.

8.2.2 North-South Corridor

The north-south corridor is rather confined to the urbanized area of DKI Jakarta, and which already exhibits a large traffic demand along the existing north-south thoroughfare, and its urban structure is considered relatively stable compared to the east-west corridor.

Therefore, a targeted role and function of the north-south corridor can be simply defined as a strengthening of the existing north-south thoroughfare.

The present situation or background is as follows :

- The population in the central business district are decreasing as shown in figures derived from the results of census in 1980 and in 1990.
- Office buildings and multi purpose buildings are realizing in the central business district and along the major arterial roads with large volume and rapid speed. On the other hand, housing developments in the southern area, where is basically a sustainable development area including the southern part of the Jakarta Ring Road are being carried with a large volume and a rapid speed.
- It is likely that bussiness and private purpose trips will marginally increase, as the commuting demand towards the central core area grows from either south or north of Jakarta. Resultantly, the major roads in the north-south direction will be constantly congested during the whole day.

- It is well-known that shortage of traffic capacity causes traffic congestion in the CBD of Jakarta. Imbalance between capacity and demand is brought about mainly by deficient road ratio. Since road transport plays an overwhelmingly important role in the transport industry in Jakarta utmost efforts should be made to improve such situation by means of both increase of road ratio and its efficiency.
- In terms of road ratio, more roads should be constructed as far as feasible; even though it becomes an elevated road on viaduct. In terms of efficiency, on the other hand, functional road network should be established, segregating medium and long distance traffic from local traffic.
- Accordingly, the Jakarta-West Java Tollway System has been developed and being extended as required. Traffic volume on arterial roads in Jakarta demonstrated a sharp growth during these decades. It implies that latent traffic demand is so high that the North-South Axis can be justified as an alternative route to the existing Jl. Thamrin/Sudirman. The simulation of the N-S Axis on the existing road network revealed that total vehicle-kilometers would have the same level but total vehicle-hours would decrease significantly, that is, significant increase in transport efficiency could be achieved.
- From technical viewpoints, the following countermeasures are taken into accounts;
 - (a) In order to avert excessive concentration of traffic at On/Off ramps, their locations will be dispersed and intended selection of service directions will be made.
 - (b) To make full use of existing parallel roads as a frontage road, On/Off ramps are provided apart from connecting cross roads.
 - (c) The open system, which toll barrier is provided not on On/Off ramps but on the through way, will be proposed. Therefore, traffic congestion would be on a tollway if extraordinary traffic should happen.

8.2.3 Relationship to Mass Transport System

Both project roads are radial arterial roads and are planned not to conflict but to support a mass transportation system through efforts to change the present urban structure to a structure pertaining to the mass transportation system.

Regarding the urban transport in Jakarta and its surrounding, it is proposed to establish a transport system, efficient combination of rail, buses and private vehicles, functioning respectively in their appropriate range of service distance and their purpose of trip.

To cope with such situation and to consider such planning elements as securing of urban functions, maintaining of regional environmental conditions and energy preservation, the low private motorization is urged by public opinions and the Jabotabek Urban Mass Transit System is proposed on the use of a combination of LRT and conventional heavy rail.

Public transportation has two options, namely car-base transport and rail-base transport. The former is represented by bus transport. Many metropolitan cities through the world rely upon urban activities, particularly commuters, by means of bus transport. The main reasons why bus transport is well-advanced, are that it can share road network and rather small investment enables to operate and maintain buses with the flexibility against the fluctuation of demand. On the contrary, rail-base transport has the variety of capacity by type. The common features are that it is necessary for rather big organization to operate and maintain transport system and to accompany with enormous initial investment.

Jakarta has been developed as a road transport oriented city where several thoroughfares sustain urban activities. On the other hand, rail-base transport oriented city has different salient features. Urban development as well as road network have been developed around station square where bus bay, taxi bay and passenger waiting area claim their priority to occupy and they lay aside private car parking in the vicinity. Accordingly, Jakarta will have more public facilities and parking places in the CBD if a new rail-base transport system is introduced.

Generally, such a development scenario can be envisaged that the arterial road network with bus transport will accommodate urban activities in short and medium term and it will foster the circumstances to make rail-base transport viable and it will eventually enable to realize the scheme of low private motorization by means of administrative measures. The administrative measures are to discourage citizens the entry into the CBD by using private vehicle, particularly in peak hours by means of imposing higher transport costs and to encourage citizens to use the public transport system by frequency, comfort, safety, certainly and cheaper cost.

It is noted that the road transport still remains the predominant role in transport industry in Jakarta even if a new transport system has been developed. The tollway network contributes the leveling of the regional developments towards realization of a balanced development between the regions, and evenly distributed results of development. The arterial road network as well as tollway not only complement rail-base traffic but also accommodate services for commuters, business trips and goods and always door-to-door service.
