nesses are to be promoted seeking to legalize the informal sector. Industry is to be promoted by creating an industrial development pole in Guaxindiba.

A water transportation terminal is to be constructed at Porto da Madama, seeking to improve mass transportation which is currently dependent on buses using the already congested Rio-Niteroi bridge, and the ferry service between Rio and Niteroi. A technical study for the boat service between Sao Goncalo (Porto da Madama) and Rio de Janeiro was completed by the Transportation Secretariat of the State in 1991. Also, railroads are to be reactivated to complement the boat service between Rio and Porto da Madama, so as to spread the benefits of improved mass transportation to residents of Sao Goncalo living far from the coast.

(4) Nova Iguacu

The Municipal Development Master Plan was formulated in 1991 with a 5-year planning horizon. The Master Plan is to have jurisdiction over the Districts of Queimados and Belford Roxo, which are soon to become independent Municipalities, until such a time as the newly established Municipalities formulate their own Development Master Plans.

The Master Plan provides basic guidelines for public and private agents on matters relating to land use, rationalization of public investments, and environmental preservation and protection, with the purpose of promoting the well-being of the people and the economic growth.

On environmental matters, the Master Plan seeks recuperation of degraded areas, adoption of alternative technology for the disposal of solid wastes and sewage. Likewise, industries to be promoted are those compatible with environmental protection. In the practical implementation of projects, coordination with other surrounding Municipalities is to be pursued, so as to achieve more efficient and integrated solutions.

Zoning includes Urban Areas, Rural Areas, and Areas of Restricted Occupation. One of the Restricted Areas is the Special Environmental Interest Zone, which is defined as those areas showing characteristics worthy of preservation or recuperation from the viewpoints of fauna and flora, topography or scenery, protection of water source or water quality, and cultural or historical values. Examples of Special Environmental Interest Zones are the Atlantic Forest, the Madureira Range, the Fazenda Sao Bernardino, and some railroad stations such as Adrianopolis, Japeri, Tingua and Rio d'Ouro. Tourism and leisure activities are to be promoted in some of the said areas such as Fazenda Sao Bernardino, Rio d'Ouro and Tingua. An example of Permanent Preservation Areas is the Tingua Biological Reserve where no activity affecting the flora and fauna is permitted.

Industrial activities, especially those of medium and large scale, should be located in the Exclusively Industrial Use Zone (ZEI) which is the Industrial District of Campo Alegre in Queimados. Small scale industries are to be permitted in Diversified Use Zones, while mini to small industries are to be permitted also in Residential Zones.

Environmental and sanitary conditions are to be improved, as preconditions for better living standards of the people, by gradually expanding sewer service coverage, by promoting community participation in the solution of sanitation problems, and by defining priority areas. Sanitation improvement is to be pursued through coordinated actions in the following areas: drainage, sewer service, solid wastes disposal, water supply, and control of disease vector.

#### (5) Nilopolis

The Municipal Development Master Plan, formulated in February 1992 with a 5-year planning horizon, has the objectives of improving the quality of life, socioeconomic development coordinated with the Baixada Fluminense-the Metropolitan Rio-the Rio de Janeiro State, so as to increase employment and to improve income distribution. Regional integration is to become especially relevant on environmental matters concerning drainage, water supply, sewer system and solid wastes disposal.

The objectives are to be pursued through a balanced land use, implementation of sectoral projects, and dynamization of economic activities. For these purposes, the Municipal Development Master Plan is to provide the basic framework and directives.

Land use is to be based on the following three macrozoning categories.

1. Urban macro-zone

2. Restricted use macro-zone (non-building area)

3. Special macro-zone (Gericino military camp)

Banned from urban areas are polluting industries and storage of explosives.

The infrastructure policy gives high priority to water supply, sewer works and solid wastes disposal. The Mayor is authorized to sign agreements with financial institutions, so as to implement relevant sectoral projects.

Macro-drainage of Sarapui and Pavuna Rivers, although the responsibility of the State government, is to be given support by the Nilopolis Municipal government, in coordination with other municipalities of the Baixada Fluminense.

(6) São João de Meriti

The Development Master Plan formulated in 1991 seeks a socially just and ecologically balanced land use in pursuance of people's welfare. The Master Plan is to regulate urban development and to guide actions of public and private agents.

Since the Municipality is fully urbanized, intensity of land use is to be balanced with available infrastructure and transportation, in addition to environmental considerations. New housing developments are to be located near employment sites, or viceversa. Mass transit is to be improved, and supply of basic sanitation is to be expanded with the purpose of improving standards of living.

(7) Duque de Caxias

The Municipality of Duque de Caxias has hired a consulting firm for the preparation of the Municipal Development Master Plan. The consulting firm submitted the first half of the job, "Basic Report on the Characteristics of the Municipality", in July 1992. This report contains basic information and data on natural and socioeconomic characteristics, land use, urban infrastructure, transportation systems, service infrastructure and financial resources of the Municipality.

The second half of the job, the Municipal Development Master Plan, is expected to be completed soon.

(8) Itaborai

As of October 1992, the Municipality of Itaborai had a draft of a Municipal Law to promulgate the Municipal Development Master Plan, but without convincing proof of actual passage of the law.

The draft of the law seeks to improve quality of life of the people by gradually expanding basic service infrastructure, preservation of natural resources especially soil and water, and reduction of pollution to acceptable levels.

(9) Mage

There is no Municipal Development Master Plan in Mage. However, legal provisions on their development activities are presumed to be up-to-date, since they were promulgated in 1991. These include the Zoning Law, the Land Parceling Law, and the Law on Municipal Works.

The Zoning Law provides for Preservation and Protection Areas, which are defined as forests and natural vegetation --including mangrove forests-- where land use is to strictly abide with the Federal Forestry Law.

The Land Parceling Law provides for protection of water courses. Land parceling is to be conducted only with prior approval granted by the Colonization and Agrarian Reform Institute (INCRA), by the Brazilian Institute for the Environment and Renewable Natural Resources (IBAMA) and by the State Forestry Institute (IEF).

(10) Rio Bonito

The Municipality of Rio Bonito has not yet prepared the Development Master Plan. Their development guidelines are contained in their Zoning Law and Land Parceling Law, both presumably promulgated in 1979. On their own recognition, these laws are grossly outdated and inadequate for present conditions. For example, housing developments are reportedly expanding at present into areas originally classified as Areas of Permanent Preservation. These were defined as forests and vegetation existing along water courses or around water bodies, on mountain tops and on slopes exceeding 45 degrees.

(11) Cachoeiras de Macacu

This Municipality has neither a Municipal Development Plan nor zoning and related laws serving as guidelines for their development activities. However, they are actively negotiating with the Inter-American Development Bank (BID) to expand their sewer service coverage. In addition, they are in the final stages of establishing an Industrial District, in which eight industries were committed to operate as of October 1992.

2.2.1.3 The Environment in the Development Plans

The State and Municipal Development Master Plans, or zoning and related laws in the absense of such Plans, were reviewed above. They all contain provisions on environmental protection, but without sufficiently concrete details on development activities. Therefore, these Development Master Plans are not specific enough to serve as basis for estimating future socioeconomic conditions in the Guanabara Bay basin.

Ironically, Cachoeiras de Macacu, which is a Municipality without a development plan and without zoning and related laws, has taken the initiative to establish an Industrial District, and to directly negotiate with BID for financing the expansion of sewer services. The sewer infrastructure usually requires large investments, whereby Municipalities usually rely on other government institutions for the provision of these services.

Municipalities can be said to have the basic legal provisions for environmental protection. Likewise, municipal governments purport to protect the environment, and to pursue the type of economic development which is compatible with the rational utilization of natural resources, in order to avoid irreversible damages to the environment. In this regard, even in the promotion of manufacturing industries, the emphasis is on "environmentally friendly" or "non-polluting" industries.

The parts that need to be strengthened are the application or enforcement of the existing laws, and the lack of specific details on types, scales and time frames of industries and other activities to be promoted as basis for socioeconomic development. Therefore, these two weaknesses need to be dealt with by the relevant State and Federal Institutions.

Concerning the enforcement of environmental legislation, the hope can be placed on the Rio de Janeiro State Development Plan, which deals with the establishment of an "environmental crime prevention force". The implementation of this idea, if coupled with necessary financial, technical and institutional support, can turn out to be a great contribution in instilling life into the numerous environmental laws, which currently are not effectively enforced.

In reference to the promotion of "non-polluting" industries, the role of FEEMA will be critical, as one of its functions is to monitor and control industrial effluents according to established water quality standards. If the monitoring and control are effectively implemented, then manufacturing industries will indeed be "non-polluting" and "environmentally friendly".

#### 2.2.2 Existing Environmental Improvement Projects

#### 2.2.2.1 Rio-Reconstruction Project

The Rio-Reconstruction Project was formulated with the World Bank financing to deal with the aftermath of the disastrous flood of February 1988. The purpose of the Project was prevention of such destructive floods, and included environmental improvement measures. The Project area includes Rio de Janeiro, Baixada Fluminense (Nilopolis, Sao Joao de Meriti, Nova Iguacu, Duque de Caxias) and Petropolis, but the bulk of investments is concentrated in the Baixada Fluminense, which is the area hardest hit by the floods. The Project is administered by GEROE (Executive Group for Recuperation and Emergency Works) to carry out construction works, acquisition of equipments, provision of new services and preparation of plans for the prevention of floods. The project components that remain to be implemented are shown in Table 2.2-1.

The basis of the Project is environmental education and provision of services for solid wastes disposal and sewer systems, as well as implementation of programs on reforestation and resettlement of families. Drainage and dredging works target rivers and channels which flow into the Guanabara Bay, such as Sarapui, Pavuna, Cunha, Iguacu, Saracuruna and Inhomirim. The Project has been continuously adjusted, and environmental improvement components to be implemented between 1992 and 1994 are summarized below.

| Component     | Foreign<br>Cost(1) | Local<br>Cost(1) | Beneficiaries<br>(2) |
|---------------|--------------------|------------------|----------------------|
| Sewer System  | 10.74              | 16.10            | 1,000,000            |
| Solid Wastes  | 2.36               | 4.38             | 2,000,000            |
| Reforestation | 3.98               | 4.38             | 1,200ha              |
| Drainage      | 54.42              | 54.42            | 3,000,000            |

2.2.2.2 Basic Sanitation Program

The detailed formulation of this huge environmental program was expected to be finalized in November 1992. It is composed of more than 20 projects on sewer systems, solid wastes disposal, drinking water supply and human resettlements in Municipalities adjacent to the Guanabara Bay. The foreign cost components of the projects are to be financed jointly by the Inter-American Development Bank (IDB) and the Overseas Economic Cooperation Fund (OECF) of Japan. For the administration of this Program, the Governor of Rio de Janeiro established the Executive Group for Pollution Control of the Guanabara Bay (GEDEG) through Decree No. 17136 of December  $12^{tn}$ , 1991. GEDEG has been recently changed to CODEG (Coordinating Commission for the Execution of the Pollution Control Program of the Guanabara Bay).

The original projects of the Program are listed below, and Table 2.2-2 presents the most recent version of the Program by component groups.

- 1. Sewer System of the Alegria Basin and Improvement of Penha Sewage Treatment Station
- 2. Sewer and Sewage Treatment System in the River Basins of Pavuna/Acari/Sao Joao de Meriti
- 3. Sewer and Sewage Treatment System of Sarapui River Basin

- 4. Sewer and Sewage Treatment System No. 2 of São Goncalo
- 5. Expansion of Icarai Sewage Treatment Station and Undersea Marine Sewage Pipe
- 6. Sewer and Sewage Treatment System for North-Central Zone of Niteroi
- 7. Water Supply System Sectorization for the Baixada Fluminense
- 8. Water Supply System Sectorization for Sao Goncalo
- 9. Operation Improvement and Micro-metering
- 10. Macro-drainage and Resettlement in the Acarai River Basin
- 11. Macro-drainage and Resettlement in the River Basins of Faria and Timbo
- 12. Treatment of Hospital Wastes
- 13. Improvement of Gramacho Metropolitan Landfill
- 14. Improvement of Collection and Final Disposal of Solid Wastes in Niteroi
- 15. Improvement of Solid Wastes Collection and Transfer Stations of Nilopolis
- 16. Improvement of Solid Wastes Collection and Transfer Stations of São João de Meriti
- 17. Improvement of Collection and Final Disposal of Solid Wastes in Mage
- 18. Improvement of Collection and Final Disposal of Solid Wastes in Duque de Caxias
- 19. Improvement of Collection and Final Disposal of Solid Wastes in Sao Goncalo
- 20. Organizational and Institutional Support for Solid Wastes Management in the Rio de Janeiro State

## 21. Complementary Environmental Projects

22. Digital Cadaster of the Municipalities in the Guanabara Bay Basin

23. Development of Cadastral Information Center of IPLANRIO

The total cost of the Program was originally estimated at US\$ 667 Million , but it has been revised up to US\$ 793 Million (US\$ 350 Million financed by the IDB, US\$ 294.2 Million by the OECF of Japan and US\$ 148.8 Million of local funds by CEDAE and the Rio de Janeiro State).

#### 2.3 Futures Socioeconomic Framework of the Guanabara Bay Basin

#### 2.3.1 Target Years of the Master Plan

There is no scientific method to set the target year of a water pollution control master plan. The method can only be subjective, although the degree will vary from project to project. For setting the target year, due consideration should be paid to ongoing plans and projects. State and Municipal development master plans are usually prepared with a 5-year planning horizon, which is too short for a large scale water pollution control plan. Worse yet, the reviewed State and Municipal development plans did not contain quantified details nor sector-specific goals. On the other hand, the World Bank financed Rio-Reconstruction Project is nearing completion, Consequently, the only relevant project to be taken into account to set the target year for the Master Plan for the Recuperation of the Guanabara Bay Ecosystem (hereinafter the "Master Plan") is the already mentioned "Basic Sanitation Program of the Guanabara Bay Basin" (hereinafter the "Program").

According to the loan request document submitted to BID in December 1992, the Program has five major components: Sanitation (Water Supply and Sewerage), Macro-drainage and Human Resettlement, Solid Wastes, Complementary Environmental Programs, and Digital Mapping and Tax Collection. The proposed implementation schedule spans from 1992 to 2005, originally estimated at a total cost of US\$ 667 Million, later revised up to US\$ 793 Million, to be jointly financed by BID, OECF of Japan, and Brazil.

The extremely large scale of the Program, and the equally large scale improvements in water quality which are expected from its implementation, make it necessary to set the target year for the Master Plan beyond the implementation period of the Program. Further, water quality improvement will not occur instantaneously after completing implementation of the Program in 2005. In addition, administrative measures, and the institutional reforms that may be needed, are estimated to require a lot of time to be implemented.

Under the foregoing considerations, the following target years are proposed for the Master Plan.

#### <u>Short-term</u>

Target year 2000: Completion of sewerage works to be implemented by the Program, that is, completion of Phase I

#### Medium-term

Target year 2010: Full completion of the Program; although a water quality improve ment project requires a longer time frame, the estimation of future conditions becomes even more difficult and unreliable

#### Long-term

The target year is not explicitly set. The goal is the recovery of the Guanabara Bay water quality to the level that prevailed during the first half of the 1960s.

#### 2.3.2 Future Socioeconomic Scenarios

Formulation of a pollution control master plan implies the need to envisage the socioeconomic situation that is likely to prevail some time in the future (target year). This will be the result of changes in population, presence or lack of a diversity of measures that the government usually implements, leading ultimately to a particular way of life and living standards. The future socioeconomic situation defines changes in discharge of pollutants, and influences the choice of pollution control measures to be applied. The reverse is also true, that is, pollution control measures have definite effects on the future socioeconomic conditions.

2.3.2.1 Bases for Future Scenarios

The present master plan has two target years: 2000 and 2010. Socioeconomic scenarios for the two target years are to be defined in terms of (1) population, (2) coverage of basic services: water supply, sewerage and solid wastes disposal, and (3) economic activities, including changes that are bound to occur in the land area under cultivation, and the sector-specific growth rates.

#### (1) Population

Population projection usually falls under the jurisdiction of official institutions, because they have access to all the necessary background data and information which are frequently unavailable to outsiders. However, the two relevant official Brazilian institutions in charge of census and statistics, IBGE at the national level and CIDE at the Rio de Janeiro State level, have no population projections.

Under this situation, the alternatives are either to use the population projection of the IDB financed Basic Sanitation Program, or use past population growth trends to subjectively estimate Municipality-specific growth rates. Using the population projection of the Basic Sanitation Program has the advantage of providing consistency to the population data for plans relating to the Guanabara Bay basin, but the drawbacks are the partial coverage of the basin and the lack of breakdown by Municipality.

(2) Coverage of Basic Services

Concerning the coverage of basic services (water supply, sewerage and solid wastes disposal), the source for future socioeconomic scenarios should normally be the regional development plans. However, the reviewed State and Municipal development plans contain broad policy objectives without sector-specific quantitative goals. In addition, the planning horizon of these development plans is usually five years, shorter than the target years for the pollution control master plan.

Consequently, the IDB financed Basic Sanitation Program for the Guanabara Bay basin contains the only concrete data that can be taken into consideration in the estimation of future coverage of solid wastes disposal services in some Municipalities.

(3) Economic Activities

Estimation of types and scales of future economic activities is the most difficult proposition, especially in view of the abnormal situation of the Brazilian economy during the past decade. The hope of relying on development plans, both at the State and Municipal levels, turned out to be impractical, because such plans generally lack sector-specific quantitative goals. Encouraging, however, is the emphasis placed on promoting "environmentally friendly" or "non-polluting" industries. This opens the possibility for estimating future pollutant discharge as reductions from present levels, instead of basing on types and scales of future industrial activities.

An alternative is to estimate future economic activities on the basis of existing data, namely, various censuses (1960, 1970, 1980 and 1985) of agriculture, industry and services. The future is to be estimated by economic sector, from base figures of selected sector-specific indicators and subjectively assumed rates of growth. The growth rates of these selected indicators should keep a balance between those showing the expanding "Brazilian miracle" economy of the 1970s and those reflecting the foreign-debt ladden sluggish economy of the 1980s.

Selected Indicators

Primary Sector : Area of land under cultivation by, Municipality in 1985

Secondary Sector : Number of employees by industry type, in Metropolitan Rio de Janeiro in 1985

Tertiary Sector : Number of employees in the food and lodging services, by Municipality in 1985

Another conceptually possible procedure in estimating future economic activities is to start from the population projections. Then, the economically active population can be estimated and proportionatelly distributed among economic sectors.

2.3.2.2 Assumptions for Future Scenarios

(1) Case 1 - Expected Scenario

Population growth: slowing and stabilizing

Basic Services : expanding as per IDB Program

Economy

: "clean" industries and services

#### POPULATION GROWTH

Population growth is assumed to slow down and stabilize around the year 2005. This is the theory of the World Bank, whereby the Brazilian population growth rate will equal the replacement rate, or zero population growth (ZPG), in the year 2005. As the overall population growth rate in Brazil between 1980 and 1991 was 1.87% per year, the natural population growth rate is assumed to be a moderate 2%.

For purposes of population projection, the Municipalities of the Guanabara Bay basin were divided into four groups on the basis of past population growth trends. Then, future population growth rates were subjectively estimated by Municipality and by time span. The assumed population growth rates will be smaller the farther into the future the relevant time span is. This reflects increasing difficulties to predict the more distant future, and can be defended on grounds of the future expansion of opportunities for women's education, which is widely recognized as the most significant factor for an effective family planning.

The assumed growth rates by Municipality and by time span in the four groups are shown in **Table 3.2-1**. The four groups are the following.

"Grown" (Rio de Janeiro, Niteroi, Nilopolis, Sao João de Meriti)

"Grown" Municipalities consist of those fully urbanized, with very high population densities. Very low population growth rates were observed in the recent past and are presumed to occur in the near future in these Municipalities. Further, the very slow population growth (0.5%-0.75%) is assumed up to 2005, when population is assumed to stabilize.

The assumed population growth rates are as follows.

1992-2000: 0.5%-0.75% 2001-2005: 0.5% 2006-2010: 0.0%

## "Growing" (Sao Goncalo, Itaborai, Rio Bonito)

"Growing" Municipalities consist of those presently growing or are likely to grow in the near future. This is based on the observation of on-going housing developments in Sao Goncalo and the expansive economy of Itaborai. These effects are likely to spill over onto Rio Bonito, which presently serves as the commercial center bridging Metropolitan Rio de Janeiro and the surrounding rural areas. The growth expected in "growing" municipalities is induced by the saturation of "grown" municipalities.

The assumed population growth rates are as follows.

1992-2000:2.0%-4.0%2001-2005:2.5%2006-2010:0.5%-1.0%

"Next-to-grow" (Mage, Cachoeiras de Macacu)

"Next-to-grow" Municipalities consist of those likely to grow slightly later than the "growing" municipalities, even though chances are that they will grow at about the same time. Mage is slowly changing from an area of weekend houses and private recreation facilities to an area with houses where people normally live and from which they commute to work. Cachoeiras de Macacu, although too far for daily commuting to Metropolitan Rio de Janeiro, is likely to have a population inflow induced by the establishment of an industrial park with the cooperation of CODIN, plus the efforts to begin installation of sewer works by the Municipal government.

The assumed population growth rates are as follows.

1992-2000: 2.0% 2001-2005: 3.0% 2006-2010: 1.0%

"Possible Growth" (Duque de Caxias, Nova Iguacu)

"Possible Growth" Municipalities consist of those relatively large communities (over half a million), practically fully urbanized, but with insufficient service infrastructure. These Municipalities are assumed to have a moderate natural growth rate. Both the World Bank and the IDB have targeted this area to improve living conditions through provision of flood control infrastructure, and services of water suppy, sewer and solid wastes disposal. Given the convenient location of these Municipalities within the Metropolitan Rio de Janeiro, if living conditions improve as a result of the World Bank and IDB projects, population inflow is likely to occur from the saturated "grown" municipalities into these "possible growth" municipalities. However, this population inflow is considered to be short lasting, quickly reaching the zero population growth stage.

The assumed population growth rates are as follows.

1992-2000: 2.0% 2001-2005: 2.5% 2006-2010: 0.0%

#### BASIC SERVICES

Service coverage rates of water supply, sewerage and solid wastes disposal are assumed by taking into consideration the IDB financed Basic Sanitation Program. In general, the following coverage is to be assumed.

\* Municipalities with IDB Projects

2000: 90%-100% 2010: 100%

\* Rio de Janeiro and Niteroi

2000: 100% 2010: 100%

\* Other Municipalities

2000: 70% 2010: 90%

Detailed growth rates by Municipality and by time span are shown in Tables 3.2-2, 3.2-3 and 3.2-4.

#### ECONOMY -

An attempt was made to reflect the Regional Development Plans, which appear to promote the service sector. Accordingly, the tertiary sector is to grow at the fastest rate. The growth of the manufacturing sector is to be relatively slow, as incentives are mainly focused on those industries without adverse environmental effects. Since manufacturing grows rather slowly, farming, in addition to the service sector, is to grow at a faster rate.

Primary Sector

The future of the primary sector is to be estimated as a function of the land area under cultivation by Municipality in 1985, which is the year with the latest available census data.

Growth rates of land area under farming were subjectively estimated by Municipality for both periods encompassing 1986-2000 and 2001-2010, as shown in **Table 3.2-5**.

#### Secondary Sector

The future of the secondary sector is to be assumed as a function of the number of employees by industry type in Metropolitan Rio de Janeiro in 1985, which is the year with the latest available census data. Because manufacturing activities are concentrated in Metropolitan Rio de Janeiro, it was deemed appropriate to represent the Guanabara Bay basin with these data rather than the Municipality-specific data. In addition, the selected industry types accounted for more than 80% of employment in the secondary sector in 1985.

Following a similar procedure as in the primary sector, growth rates of the number of employees by industry type were subjectively estimated for Metropolitan Rio de Janeiro for both periods encompassing 1986-2000 and 2001-2010, as shown in **Table 3.2-6**.

#### Tertiary Sector

The future of the tertiary sector is to be assumed as a function of the number of employees in the lodging and food service by Municipality in 1985, which is the year with the latest available census data. Following a similar procedure as in the primary and secondary sectors, growth rates of the number of employees in the lodging and food service were subjectively estimated by Municipality for the two periods encompassing 1986-2000 and 2001-2010, as shown in Table 3.2-7.

(2) Case 2 - Pessimistic Scenario

Population growth: increasing even after 2005

|   | Services | : | lower | ec               | verage  | than | the  | IDB     |
|---|----------|---|-------|------------------|---------|------|------|---------|
|   |          |   |       |                  | Progr   | am   |      |         |
| : | Economy  | : | "dirt | 7 <sup>11°</sup> | industr | ies  | keep | growing |

#### POPULATION GROWTH

The World Bank assumption of zero population growth since the year 2005 is assumed to materialize only in the Municipalities of Nilopolis and Sao Joao de Meriti, which at present have the highest population densities. Population growth is assumed to continue into the future, albeit at a slower rate. However, for the 1992-2000 period, population growth rates are assumed to be the same as in Case 1, as shown in Table 3.2-1 and summarized below.

"Grown" Municipalities

1992-2000: 0.5%-0.75% 2001-2005: 0.5% 2006-2010: 0.0%-0.5%

"Growing" Municipalities

1992-2000: 2.0%-4.0% 2001-2005: 2.5% 2006-2010: 0.5%-1.0%

"Next-to-Grow" Municipalities

| 1992-2000: | 2.0% |
|------------|------|
| 2001-2005: | 3.0% |
| 2006-2010: | 1.0% |

"Possible Growth" Municipalities

| 1992-2000: | 2.0% |
|------------|------|
| 2001-2005: | 2.5% |
| 2006-2010: | 1.0% |

## BASIC SERVICES

Service coverage of water supply, sewerage and solid wastes disposal is assumed to be lower than the target of the IDB financed Basic Sanitation Program. The assumed coverage rates are shown in **Tables 3.2-2 to 3.2-4** and are summarized as follows.

\* Municipalities with IDB Projects

2000: 70% - 90% 2010: 80% - 100%

\* Rio de Janeiro and Niteroi (same as Case 1)

2000: 100% 2010: 100%

\* Other Municipalities

2000: 50% - 70% 2010: 70% - 90%

## ECONOMY

The difference in assumptions from Case 1 concerning economic activities refers mostly to the secondary sector. Here, the manufacturing sector, including "polluting" industries, are assumed to keep growing at a faster rate than the primary and the tertiary sectors. Accordingly, the growth rates are to be relatively slower in farming and the service sectors. The assumed growth rates are shown in **Tables 3.2-5 to 3.2-7**.

## 2.3.3 Socioeconomic Framework in the Target Years

The socioeconomic scenarios described in Section 3.2 served as bases for estimating the socioeconomic framework for the Guanabara Bay basin in the two target years 2000 and 2010. Details are shown in Tables 3.3-1 to 3.3-7, and summarized in Table 3.3-8.

#### 2.3.3.1 Population

The 1991 population census data for the Municipalities comprising the Guanabara Bay basin were projected to the target years with the assumed growth rates, and resulted in the summary below. Scenario 1 represents a slowing population growth, stabilizing around the year 2005 according to the World Bank theory, while Scenario 2 assumes that the population in most Municipalities keeps growing after 2005.

1991 Census

9,471,951

Scenario 1 2000 2010 Growth rates 1992-2000 2001-2010

11,376,950 1.29%/yr. 0.68%/yr.

10,629,649

Scenario 2 2000 2010 Growth rates 1992-2000 2001-2010

10,629,649 11,670,796 1.29%/yr.

0.94%/yr.

## 2.3.3.2 Coverage of Basic Services

The coverage of basic services in the Guanabara Bay basin, at present and the projections for the two scenarios, is presented below. The figure in parentheses refers to the percentage of the serviced population relative to total population. Scenario 1 represents achievements of coverage goals consistent with the BID Basic Sanitation Program, while Scenario 2 assumes lower coverage.

| (1) | Solid Wastes Disposal |                 |         |
|-----|-----------------------|-----------------|---------|
| ·   | Present               | 7,115,316       | (75.1%) |
|     | Scenario 1            |                 |         |
|     | 2000                  | 9,831,045       | (Q9:59) |
|     | 2010                  | 11,163,463      |         |
| -   | 2010                  | 11,100,400      | (00.10) |
|     | Scenario 2            |                 |         |
|     | 2000                  | 8,962,932       | (84.3%) |
|     | 2010                  | 10,649,977      |         |
|     |                       | - • · - • · · · |         |
|     |                       |                 |         |
| (2) | Water Supply          |                 |         |
|     | Present               | 7,390,507       | (78.0%) |
|     | Scenario 1            |                 |         |
|     | 2000                  | 10,176,766      | (95.7%) |
|     | 2010                  | 11,336,825      |         |
|     |                       |                 |         |
|     | Scenario 2            | (d. 1)          |         |
|     | 2000                  | 9,558,759       | (89.9%) |
| -   | 2010                  | 11,132,674      |         |
|     | : .                   |                 |         |
| (3) | Sewerage              |                 |         |
|     | Present               | 5,272,870       | (55.7%) |
|     | Scenario 1            | · · ·           |         |
|     | 2000                  | 10,069,896      | (94.7%) |
|     | 2010                  | 11,309,529      |         |

Scenario 2 2000 2010

8,531,207 (80.3%) 10,874,346 (93.2%)

## 2.3.3.3 Economy

The economic framework in the Guanabara Bay basin is described in reference to the sectoral growth rates. Scenario 1 represents a relatively slow growth rate in the manufacturing sector, due to the emphasis in the service sector and "clean" industries. Consequently, the relatively strong primary sector growth reflects absorption of some labor displaced from the manufacturing sector. Accordingly, there is an increase in the cultivated land area.

On the contrary, Scenario 2 represents a less than expected growth rate in the service sector, which coupled with the continued growth of "dirty" industry types, provide employment opportunities in the secondary sector. Accordingly, the primary sector grows relatively less and the cultivated land area is smaller.

(1) Primary Sector

Cultivated land area (ha)

Present (1985) 118,488 Scenario 1 2000 134,916 2010 140,811 Scenario 2 2000 122,117 2010 124,630

## 2.4 Benefits from Water Quality Improvement of the Guanabara Bay

Evaluation of benefits from a purely environmetal improvement project poses serious difficulties in the practical application of recently developed theoretical concepts. These difficulties range from the lack of reliable and sufficiently long time-series data, to the unproven methods of data collection due to the general lack of consciousness about environmental problems among the people, who will ultimately determine the success of an environmental improvement project.

### 2.4.1 Assessment of Benefits

In the assessment of benefits from water quality improvements, attention should be paid to both the benefits accrued and the costs avoided. This means that benefits should include those effects easily recognized as straightforward benefits and those effects that lead to cost avoidance. The assessment of these broadly interpreted benefits entails critical problems due to the uncertainty of information and the difficulties involved not only in the identification of benefits but also in the quantification of identified benefits.

When a pollution abatement project is undertaken to reach desired environmental quality targets, the gathering of relevant information on the relationship between pollution and environmental quality requires very careful research and technical analysis. Even if benefits are identified as effects, for example, on expanded recreation opportunities, or on health and productivity improvements, the ensuing quantification is still extremely difficult.

2.4.1.1 Criteria for Benefit Assessment

Conceptually, the following criteria can help as guides in the identification and quantification of benefits.

(1) Complement to another good

When water quality is improved, it might generate consumption of other goods, such as the increased demand for beach areas for swimming or fishing.

## (2) Infrastructure protection

Polluted waters may cause damage to industrial, transportation or household infrastructure, which requires adoption of preventive measures (additional expenditures) to protect against these adverse effects of pollution. If these expenditures in the form of increased frequency of painting, or corrosion protection, can be reduced or eliminated altogether, then the difference in expenditures can be quantified as benefits.

(3) Production input

If the pollution abatement project lowers production costs, benefits accrue either to consumers as reduced output price or to producers as increased profits.

(4) Land value appreciation

The improvement of environmental characteristics increases the value of the land as a result of intensification in agricultural, commercial or residential uses.

(5) Willingness to pay

Improvements in water quality may cause people to react positively, inducing them to show willingness to pay for the improved environmental quality. However, it is difficult to make individuals conceptualize the expected improvements in water quality, thereby leading to overestimation or underestimation of expected personal benefits, which results in an inaccurate willingness to pay.

2.4.1.2 Alternative Criteria

A broader classification of both the quantifiable and nonquantifiable categories of benefits can be as follows.

## (1) Current user benefits

#### a. Direct use (quantifiable)

1. In water

\* Recreation

Contact : swimming Non-contact: fishing, boating

\* Commercial: navigation, fishing

2. Withdrawal: industrial/commercial cooling

b. Indirect use (difficult to quantify)

1. Recreation: near water hiking, birdwatching

2. Relaxation: pleasant scenery

3. Aesthetic : enhancement of nearby site amenities

(2) Intrinsic benefits (non-quantifiable)

a. Potential use

Option value: amount that an individual may be willing to pay for the right to use a water body (over and above the expected user values) even though such a right may never be exercised

b. No use

Existence value: individual's willingness to pay simply for the knowledge that a resource exists even if never used.

\* Bequest: to present or future generation

\* Vicarious consumption: enjoyment from the knowledge that others are using the resource

## 2.4.1.3 Bases for Benefits in the Guanabara Bay Basin

A questionnaire survey was conducted on the environmental awareness of the residents in the Guanabara Bay basin. The survey showed that 93.6% of respondents regarded the bay water as dirty or very dirty, and its major causes were seen as domestic waste water by 46.7%, factory waste water by 25.6%, garbage thrown into tributary rivers or directly into the bay by 12.3%, and garbage/oil from ships by 8.7%. The resident awareness on the weight of waste water as a cause of pollution was indicated by those respondents favoring control or rigorous control of domestic waste water (92.8%) and of factory waste water (94.8%).

Facing the described situation, 89.6% of respondents thought that the Guanabara Bay water should be cleaned soon or cleaned if possible. The strong interest in improving the water quality stemmed from the present use of the bay, in which 21.3% of respondents claimed to be using the bay beaches for recreation, 21.2% using the ferry boat service, 16.9% enjoying regular strolls along beaches, 16.8% fishing as full-time profession in the bay, 9.6% fishing occasionally, and 7.9% enjoying the scenery.

The respondents planned utilization of the bay, if the bay water were to be cleaned, contrasted sharply with the present use in the weight given to fishing and recreation. In this regard, 31.3% of respondents thought they would use the bay for fishing, 30.8% for swimming and enjoying beaches, and 14.9% for practicing marine sports.

The questionnaire survey clarified the close relationship between the Guanabara Bay and the basin residents, as well as their strong interest in the improvement of the bay water quality. These provide the basic background for estimating the benefits from improving the Guanabara Bay ecosystem. From the criteria mentioned in Sections 4.1.1 and 4.1.2, the benefits from the improved Guanabara Bay ecosystem were chosen to be those that were already identified and quantified by FEEMA, as listed below.

(1) Recreation benefits: water contact

These benefits involve swimming and water sports, and depend on the number of persons swimming or practicing water sports, which in turn depend mostly on the available beach area. These benefits are underscored by the numerous bay beaches that are contaminated and hence unsuitable for recreation. Therefore, the nearby residents are forced to travel longer distances seeking cleaner beaches for recreation, which give rise to overcrowding of ocean beaches. The fact that 45.7% of respondents wanted the Guanabara Bay in the future to be clean enough for swimming/enjoying beaches and for the practice of marine sports is a good indication on the importance of these benefits.

## (2) Recreation benefits: boating and fishing

These benefits involve boats of a specified tonnage class, and consist of avoidable costs in the absence of pollution in the Guanabara Bay. These avoidable costs refer to additional operation and maintenance costs due to pollution and due to longer sailing distance in search of cleaner water areas for recreation boating and fishing. These benefits are likely to accrue to the 9.6% of respondents who at present fish occasionally, as well as to recreation boaters.

#### (3) Commercial shipping benefits

These benefits involve avoidable dredging costs in the case of large ocean going vessels requiring wharfage within the Guanabara Bay, and avoidable operation and maintenance costs in the case of small passenger boats operating within the bay. The likely beneficiaries are the 21.2% of respondents who at present use the boat service and may enjoy lower fares which can be passed on by the boat operators as a result of reduced operation and maintenance costs.

(4) Commercial fishing benefits

These benefits involve changes in fishery production, and refer to declining shrimp catch in the Guanabara Bay in recent decades, due presumably to worsening pollution level in the bay. Conversely, if the quality of the bay water were to improve, shrimp catch would again increase. These benefits are underscored by 45.1% of respondents who thought the Guanabara Bay should be cleaned to the level of assuring increasing production of fish, shrimp and shellfish, as well as by the 31.3% of respondents who wanted to use the bay for fishing in the future.

## (5) Land value appreciation

These benefits involve the land located along the shoreline of the Guanabara Bay, and refer to its value being inversely correlated with the pollution level of the bay water, that is, higher land value with clean water and lower land value with polluted water.

#### (6) Health improvement

This potentially large benefit will not be taken into consideration in this project, because the technique of measuring changes in human productivity poses major ethical problems. Human life or the psychological costs of illness and death should not be subject to monetary valuation, even if technically possible, except under the following restricted conditions.

The loss-of-earnings approach can be applied to value environmental effects when (a) a direct cause-and-effect relationship can be established and the etiology of the disease is clearly identifiable; (b) the precise economic value of earnings and medical care is known; and (c) the illness is relatively short, not lifethreatening and without long-term effects. This means that chronic and long lasting illness, which is likely to be the health effects of environmental pollution, are hard to handle. The basic problem refers to the lack of a clear definition in the exact cut-off point between short-lasting and long-lasting illnesses.

The above three conditions do not prevail in the case of the Guanabara Bay basin. The large number of pollution sources in the basin make the relationship between cause and effect difficult to establish. Moreover, the etiology is not well established, that is, the effects of the polluted bay water cannot be translated into health consequences. These effects are likely to be debilitating but not completely disabling. For instance, in the case of parasitic infections, the valuation problem is complicated because the victim appears to be healthy but functions at less than full potential.

#### 2.4.2 Benefit Types in the Guanabara Bay Basin

In the case of Guanabara Bay, potential benefits from mproving its water quality have been studied for nearly 20 years by Mr. Victor Coelho of FEEMA, even before establishment of FEEMA, while he was still with the Institute for Sanitary Engineering of the Science and Technology Secretariat. Mr. Coelho incorporated the basic concepts of recent theoretical evaluation methods into practical calculation procedures which are easily understood. Therefore, it was agreed to update relevant aspects of Mr. Coelho's work to make it applicable to the present situation of the Guanabara Bay basin. Accordingly, it is appropriate to describe Mr. Coelho's original work, which is the following.

Mr. Coelho estimated potential benefits stemming from the possible water utilization types, which were classified as follows:

- (1) Recreation: water contact
- (2) Recreation: boating and fishing
- (3) Commercial shipping
  - (4) Commercial fishing
  - (5) Land value appreciation

Mr. Coelho's calculations based on 1974 data for the above water utilization types yielded the following estimated benefits.

(1) Recreation benefits: water contact

These benefits involved swimming and water sports, and were assumed to depend on the number of persons swimming or practicing water sports. The number of swimmers was calculated on the basis of the saturation population of the beaches of the Guanabara Bay as a function of the area of these beaches. The saturation population was calculated assuming 2 sq.m. of beach per swimmer in crowded beaches, and 10 sq.m. of beach per swimmer in uncrowded beaches. Then, the saturation population of the Guanabara Bay beaches was estimated at 197,340 persons.

Next, the utilization rate of beaches was estimated as a function of climate or season, day of the week, and school vacation time. The assumed beach utilization rate was expressed as percentage of the saturation population, as indicated below.

| Sunday:    |                 | 70%        |
|------------|-----------------|------------|
| Saturday:  |                 | 50%        |
| Work days: | school vacation | months 20% |
|            | other months    | 10%        |

The resulting number of the saturation population of swimmers in the Guanabara Bay beaches was estimated at 11,922,600 persons per year.

To give monetary value to benefits from recreation swimmers, an extreme scenario was assumed whereby the Guanabara Bay beaches would be so polluted as to preclude any swimming activity. Then, the residents who wished to go swimming would have to go to ocean beaches outside the Guanabara Bay. In this case, the time spent to go to more distant beaches, and the added transportation costs could be quantified. The following was assumed.

| Hourly wage (Cr\$):            | 4.00 |
|--------------------------------|------|
| Hourly recreation value (Cr\$) | 6.00 |
| Travel time (hours):           | 2.00 |
| Transportation cost (Cr\$)     | 2.00 |

For a family of 5 in which two were wage earners, the following quantification could be made.

| Two hours of recreation for 2 persons (Cr\$) | 24.00 |
|--|-------|
| Transportation costs for 5 persons (Cr\$)    | 10.00 |
|  |       |
| Total for 5 persons (Cr\$)                   | 34.00 |
| Benefit per person (Cr\$)                    | 6.80  |
|  |       |

Thus, total benefits, or avoidable costs if the Guanabara Bay beaches were safe to swim for nearly 12 million swimmers per year, would amount to Cr\$81,600,000 per year.

(2) Recreation benefits: boating and fishing

To quantify this recreation benefit, the number of boats in the Guanabara Bay was classified by tonnage, with the following results. Less than 10 ton From 10 to 20 ton More than 20 ton 7,270 boats 300 boats 630 boats

Boats of less than 10 ton were assumed to be suitable for recreation fishing and boating. Then, based on a questionnaire survey, the additional operation and maintenance costs due to pollution were estimated to be Cr\$ 200 per boat per year.

Also assumed was that, due to increased pollution, some of these recreation boaters would prefer to go outside the Guanabara Bay. They were assumed to consist of 2,000 motor boats and 1,000 sail boats, incurring additional costs of Cr\$ 50 and Cr\$ 10, respectively, per boat per trip. These boaters going out of the Guanabara Bay were assumed to do so on alternate weeks, that is, 26 times a year. Then, the potential benefits, or avoidable costs if pollution was prevented, would be as follows.

(3) Commercial shipping benefits

The benefits, or avoidable costs, from commercial shipping were considered under the two categories of ocean going vessels and those restricting transportation services to inside the Guanabara Bay. For ocean going vessels that needed wharfage in ports within the Guanabara Bay, the benefits would consist of avoidable dredging costs. These were estimated on the basis of 10 cu.m/sec. of sewage inflow containing 4 ml/l of settling solids, resulting in 1,261,440 cu.m. per year of settled silt and mud. Dredging at the assumed unit price of Cr\$ 7.00/cu.m., would cost an estimated Cr\$ 8,830,000 per year.

Dredging costs would have been a lot higher if proper account was taken of the siltation resulting from the inflow of river discharge.

Benefits from passenger transportation in the Guanabara Bay was estimated under the assumptions of transportation by large ferry boats and by small high speed boats. Large ferry boats were assumed to be free of pollution damages. On the other hand, small passenger boats were assumed to require additional costs due to frequent damages to the propeller caused by floating debris. These additional costs were assumed to be 20 propeller changes per boat per year, and the need for a monthly hull painting to prevent excessive corrosion. These additional operation and maintenance costs were estimated at Cr\$ 73,000 per month, amounting to Cr\$ 876,000 per year for the fleet.

(4) Commercial fishing benefits

Shrimp catch in the Guanabara Bay in 1955 was 330 ton, but went down to 24 ton in 1972. The reduced shrimp catch, presumably due to increased pollution (siltation, landfill, oil spill), at the assumed unit price of Cr\$ 13.00/kg amounted to Cr\$ 3,978,000 per year.

The benefits from commercial fishing would have been much larger if other fish species were included.

(5) Land Value Appreciation

The value of land is undoubtedly higher if located on water bodies with clean water rather than with polluted water. Therefore, when a polluted water body is cleaned up, the value of land along its shoreline is expected to increase.

To quantify the above benefits, the Guanabara Bay was assumed to have a 130km perimeter or shoreline, which together with the estimated 70km coastline of the islands within the bay, would result in a 200km total shoreline. Of these, 120km of shoreline were assumed to be suitable for urbanization. Further assuming as urbanization land a 100m tract from the shoreline, the urbanization area would be 12 million sq.m., which at the average unit price of Cr\$ 50/sq.m., gave a total value of Cr\$ 600,000,000. A percentage of this value would accrue as benefits from improving the water quality or the ecosystem of the Guanabara Bay.

## 2.4.3 Valuation of the Selected Benefits

Section 4.1 presented a general classification of the possible benefits that may be expected from the improvement of the water quality of the Guanabara Bay. Benefit estimation is to be based on the procedure used by FEEMA, by updating the relevant information and expressing the value in terms of the American dollar. Of the many types of benefits estimated by FEEMA, the following update refers to the benefits from water contact recreation. Also estimated was one type of benefit that the FEEMA estimation did not quantify thoroughly, and this concerns the appreciation of the value of the land surrounding the water body.

#### (1) Water contact recreation benefits

These benefits refer to the value of recreation in the Guanabara Bay beaches. Benefit estimation is based on the saturation population of beaches, the hourly value of recreation, and the value of transportation.

#### a. Saturation population

The saturation population is a function of the beach area. Table 4.3-1 lists the beaches in the Guanabara Bay, along with the estimated width and length. Consequently, the total beach area in the Guanabara Bay is estimated at 1,111,500 sq.m.

The beach area per person was estimated at 5 sq.m. for Flamengo, Botafogo, Icarai and San Francisco, while 10 sq.m. per person was estimated for the remaining beaches. The resulting saturation population of the Guanabara Bay beaches was estimated at 152,950 (Table 4.3-1).

b. Number of potential beach users per year

The number of potential beach users was estimated using the following assumptions.

Hot months (November to April)

Sunday: 100% of the saturation population (26 days) Saturday:70% of the saturation population (26 days)

1.2

Weekdays:

Summer vacation (3 months): 30% of sat. pop. (65 days) Other months (3months): 15% of sat. pop. (65 days)

Cool months (May to October)

Sunday: 70% of the saturation population (26 days) Saturday:50% of the saturation population (26 days)

Weekdays:

Winter vacation (2 weeks): 20% of sat. pop. (10 days) Other months: 10% of sat. pop. (120 days)

Table 4.3-2 shows that the number of potential beach users in the Guanabara Bay is 18,147, 518 persons.

c. Value of recreation

The value of recreation is estimated by assuming the following.

- Salary: US\$100 (minimum wage)
- Monthly working hours: 176
- Hourly wage: US\$0.57/hr.
- Value of recreation: 1.5 hourly wage = US\$0.85
- Family size: 5, of which 2 are wage earners
- Transportation cost: US\$2.00 per person round trip
- Time spent on the beach: 2 hours

Then, the value of recreation is the following.

| 2 | hours : | x 2 | persons  | x US\$0.85 | =        | US\$ | 3.40  |
|---|---------|-----|----------|------------|----------|------|-------|
| 5 | person  | s x | US\$2.00 | (transp.)  | =        | US\$ | 10.00 |
| ÷ |         |     |          |            | <u> </u> |      |       |
|   |         | T   | otal 5 p | ersons     |          | US\$ | 13.40 |

The value per person per visit would be US\$13.40 divided by 5, that is, US\$2.68. This value should be multiplied by the number of potential beach users per year.

US\$2.68 x 18,147,518 persons = US\$48,635,348/year

If it is arbitrarily assumed that one/fourth of potential beach users are induced to practice water contact recreation by the cleaner water of the Guanabara Bay, then the benefits from this specific recreation type would amount to US\$ 12,158,837 per year. This is obviously an underestimation, since the basis for calculation is the minimum wage.

This is a flow of benefits to accrue over a future time period, presumed to be 30 years, during which the improvement in the Guanabara Bay water quality and the public perception of it are assumed to remain unchanged. If it is further assumed that this flow of benefits accrues between the 11<sup>th</sup> year and the 30<sup>th</sup> year, then the present value of contact recreation benefits discounted at 10% amounts to US\$ 39,910,045.

(2) Land value appreciation

The appreciation of the value of the land surrounding a water body is understood to be a summary measure, which includes all the beneficial effects from the water quality improvement. The land value appreciation depends on the unit value of land and the distance from the shore. The benefit estimation is based on the following.

## a. Unit value of land (US\$/sq.m.)

Values provided by realtors

| Flamengo                              | US\$1,260/sq.m. |
|---------------------------------------|-----------------|
| Botafogo                              | US\$1,160/sq.m. |
| Ramos                                 | US\$ 725/sq.m.  |
| Urca                                  | US\$1,525/sq.m. |
| I. do Governador                      | US\$ 485/sq.m.  |
| Maua                                  | US\$ 5/sq.m.    |
| · · · · · · · · · · · · · · · · · · · |                 |

Assumed values

| Icarai            | US\$ | 500/sq.m. |
|-------------------|------|-----------|
| San Francisco     | US\$ | 500/sq.m. |
| Remaining beaches | US\$ | 50/sq.m.  |
| Non-beach         | US\$ | 1/sq.m.   |

b. Distance from the beach

A study by the Environmental Protection Agency in the United States found that the improvement in water quality affected the value of the land surrounding the water body. The appreciation of the land ranged from 8% to 24%, and the value appreciation disappeared beyond 4,000 ft. from the shore.

Accordingly, the estimation of value appreciation is based on the following assumptions.

Distance from the beach

% Value appreciation

| Up to 100m   |  | 24% |
|--------------|--|-----|
| 100m - 500m  |  | 15% |
| 500m - 1000m |  | 8%  |
|              |  |     |

#### c. Total value

Table 4.3-3 shows that the total value of land appreciation amounts to US\$ 1,733,858,000. This is a one-time accrual of stock benefits, which are assumed to encompass all the benefits that can be derived from the improvement in the water quality of the Guanabara Bay.

If it is further assumed that the land value appreciation occurs in the 15th year, then the present value of these benefits discounted at 10% amounts to US\$415,071,820.

| : | Table 4.3.1<br>Beach | Area and<br>Width | Saturation<br>Length | Popula <sup>†</sup><br>Area |       | uanabara B<br>on Populat |        |
|---|----------------------|-------------------|----------------------|-----------------------------|-------|--------------------------|--------|

# CHAPTER 3

# POLLUTION SOURCES

## CHAPTER 3

## POLLUTION SOURCES

#### 3.1 INDUSTRIAL POLLUTION SOURCES

#### 3.1.1 Point Pollution Sources

The point pollution sources in the Guanabara Bay Basin consist of domestic sanitary sewage, industrial waste and urban solid waste. These pollution sources are managed by the following different governmental institutions:

- (1) Sanitary sewage (domestic wastewater): Companhia Estadual de Aguas e Esgoto - CEDAE
- (2) Industrial waste: Fundacao Estadual de Engenharia do Meio Ambiente - FEEMA
- (3) Urban solid waste:
  Companhia de Limpeza Urbana COMLURB.
  Rio de Janeiro State Government Municipalities.

## 3.1.1.1 Sanitary Sewage (Domestic Wastewater)

The sanitary sewage point pollution sources are divided into raw sanitary sewage point pollution sources and treated sanitary sewage point pollution sources.

(1) Raw Sanitary Sewage

Most of the sanitary sewerage basins located in the Greater Rio de Janeiro area are not covered by complete sanitary sewage systems, including wastewater collection and treatment.

In the central and north area of Rio de Janeiro City the sanitary sewage system was built over a hundred years ago. The treatment plants have stopped working, but the wastewater collection system is still working and discharging raw sanitary sewage directly into Guanabara Bay. Further, the existing urban drainage system, small channels and rivers, also contribute to Guanabara Bay, raw sanitary sewage is discharged from many points such as hospitals, sporting clubs, industry and commerce, the port, the airport and bus stations.

These discharge points are called: raw sanitary sewage point pollution sources. The sanitary sewage basins of Arsenal, Cais di Porto, Mangue, Sao Cristovao, Alegria are under CEDAE's responsibility and will be part of the future Alegria Wastewater Treatment Plant. The Paqueta Sewerage Basin, a small island located in Guanabara Bay and the North Niteroi Sewerage Basin contain wastewater collection systems and are also considered as point pollution sources.

Table 3.1-1 shows the discharge points of raw sanitary sewage, and corresponding sanitary sewerage basins.

#### (2) Treated Sanitary Sewage

As was mentioned before, few sanitary sewerage basins are covered by complete sanitary sewerage treatment systems. They represent a small percentage of the total sanitary sewage production that contributes to Guanabara Bay.

Table 3.1-2 shows the point pollution sources treated sanitary sewage, referring to each wastewater treatment plant. INFRAERO's Wastewater Treatment Plant, one of these points, is responsible for the sanitary sewage from the Rio de Janeiro International Airport, located on Ilha do Governador.

All the others are CEDAE's responsibility. As a result, this table shows the remaining pollution load after treatment.

#### 3.1.1.2 Industrial Wastewater

The industries located around Guanabara Bay are also considered point pollution sources.

FEEMA recently listed 455 factories which contributed about 90% of all organic substances discharged into Guanabara Bay. Table 3.1-3 shows the name, location and estimated pollution loads of the 117 heaviest contributors of pollution loads into the Guanabara Bay Basin selected from the FEEMA/DECOM list arranged in 1993. Unfortunately, the COD and oil in the effluent load has not been calculated.

The example of a Questionnaire filled out by all factories is shown in Table 3.1-4.

| TOTAL  |              |               |          | 227.873  | 5.489,4      |

Reference:

- 1 TSS-01, TSS-02, TSS-03, TSS-06, TSS-07 and TSS-08 flow and pollution load average values, based on Annual Report, 1991. Operation and Treatment Division. Wastewater Superintendence. Operation and Maintenance Directory - CEDAE
- 2 TSS-04 and TSS-05 flow and BOD effluent are average values based on Monthly Reports. Faulhaber Operation and Maintenance Engineering S/A. INFRAERO.

## Reference:

## 1-Points RSS-01, RSS-02, RSS-03, RSS-04, RSS-05

1.1-Domestic sewage per capita flow = 256 l/hab.d and average BOD = 240 mg/l:

Alegria Wastewater Treatment Plant Design. Report No.4. Calculation and Description Memorial Multiservice Consultant Engineering S/A 1991.

1.2-Pumping station flow, sewerage basin area, sewer system length and population. North Area of Rio de Janeiro Sewerage System Final Report, 1991. Wastewater Superintendence. Operation and Maintenance Directory - CEDAE

## 2-Point RSS-06

- 2.1-Domestic sewage per capita flow = 240 l/hab.d, sewerage basin area and population: Niteroi Centro Norte Sewage Final Disposal Design. STE Consultant Engineering S/A. August, 1988.
- 2.2-Average BOD = 200 mg/1: Ponta de Areia Wastewater Treatment Plant Design. STE Consultant Engineering S/A. January, 1991.

3-Point RSS-07

3.1-Population:

National Demographic Research, 1991 Brazilian Institute of Geographic and Statistics -IBGE.

3.2-Domestic Sewage per capita flow equals to 200 l/hab.d: Technical Normalization NB-41 (Septic Tank). Brazilian Association of Technical Normalization -ABNT

3.3-Pollution load per capita equals to 54g. BOD/hab.d based on CEDAE's usual application for wastewater characterization.

## 3.1.2 Production of Raw Sanitary Sewage and Urban Solid Waste

## 3.1.2.1 Production of Raw Sanitary Sewage

Table 3.1-5 shows the total production of raw sanitary sewage for each sewerage basin of Guanabara Bay, considering the total flow and the pollution load. The calculation was made applying the domestic sewage per capita flow and the average BOD of each sewerage basin, according to the reference listed previously.

# Table 3.1-5 Total Production of Raw sanitary Sewage in Guanabara Bay Sewerage basins

## 3.1.2.2 Production of Urban Solid Waste

Table 3.1-6 shows the urban solid waste production for each city in the Great or Rio de Janeiro area.

The population is based on the National Demographic Research, 1991.

Brazilian Institute for Geographic and Statistics - IBGE.

The per capita production is based on Guanabara Bay Ecosystem Recuperation.

Table 3.1-6 Urban Solid Waste Production

The Urban Solid Waste Production is not the influence values for the Guanabara Bay (landfill) as it show in table 1.3.1.

## 3.2 SEWER SYSTEMS AND SEWAGE TREATMENT PLANT

#### 3.2.1 Sewer Systems

CEDAE is responsible for the implementation, control and operation of the Greater Rio de Janeiro Sewer Systems.

The existing sewer systems of the Greater Rio de Janeiro area (wastewater collection systems) are shown in **Table 3.1-2** as point pollution sources.

In Greater Rio de Janeiro, - the central and northern areas of Rio de Janeiro City, Paqueta Island, Centro Norte and Icarai areas of Niteroi City are covered by sewer systems.

The Central and northern areas of Rio de Janeiro City contain several sewerage basins by system, according to Table 3.2-1.

Paqueta Island has 11km of sewer pipelines, the final disposal point of the sewage is Guanabara Bay.

Niteroi Central Norte located in Niteroi City has km of sewer pipeline.

Icarai also located in Niteroi City has km of sewer pipeline and the final disposal of the sewage is Guanabara Bay

# CHAPTER 4

# INDUSTRIAL WASTEWATER CONTROL AND ITS CHARACTERIZATION

### CHAPTER 4

### INDUSTRIAL WASTEWATER CONTROL AND ITS CHARACTERIZATION - Monitoring Results of Industrial Wastewater

### 4.1 Current Situation of Industrial Wastewater

The Guanabara Bay basin constitutes one of the most important industrial parks in the country it accounts for, approximately, 6,000 potentially polluting factories involved in various activities, including chemical, petrochemical, food, textile, beverage, metal finishing, etc.

The oil refinery at Duque de Caxias, part of the PETROBRAS petrochemical complex, contributes greatly in terms of industrial pollution. Its liquid effluents contain, significant amounts of oil and other organic matter, heavy metals, phenols and toxic organic substances that are possibly carcinogenic or mutagenic.

Many seafood producing factories located in the municipalities of Niteroi and Sao Goncalo generate large volumes of effluents with high concentrations of oil and organic matter, releasing also, unpleasant smells which incommodes the inhabitants of the region. Almost all factories in this industry do not have treatment facilities.

In the metal finishing sector, the total pollution discharged from the many small scale factories contributes significantly.

In 1988, it was estimated that about 9.5 t/d of oil was discharged into the bay, 3.5 t/d from the Duque de Caxias refinery, 1.0 t/d from the marine terminal, 2.8 t/d from other industries and 2.2 t/d from the 40 shipyards and 2,000 gasoline stands.

An oil control plan started in 1988 to reduce by, approximately 50% to oil discharged into Guanabara Bay. It was planned to install small scale oil separators in each gasoline stand to control of discharge of oil but this plan was unsuccessful doe to the economic recession.

Currently 23 plants have disposal treatment facilities in operation and 13 others are in the process of constructing. The names of these plants are listed in Table 4.1-1 and Table 4.1-2.

### 4.2 FEEMA Monitoring Program

FEEMA selected recently 455 factories which contribute 90% of all organic matter discharged into Guanabara Bay.

Total BOD, heavy metals and oil loads generated by all factories are estimated at 120 t/d, 0.55 t/d and 4.8 t/d, respectively.

To effectively control these pollution sources, FEEMA recently drew up an industrial waste control program for the Guanabara Bay basin following a request from the I.D.B.

According to this program, FEEMA will obligate 455 factories to treat their wastewater during the 4 years of the program. These factories are listed in Table 4.2-1.

The expected reduction of BOD, heavy metals and oil loads for each year is shown in Table 4.2-2.

Table 4.2-3 shows the names and location and estimated pollution loads of the 150 heaviest contributors of pollution loads in the Guanabara Bay basin selected by FEEMA, taking into consideration their activities.

Fig. 4.2-1 shows the general geographical distribution in the Guanabara basin of these factories. As it can be seen, most of the factories are located on the west and north west sides of the Guanabara basin, especially, in the Rio Timbo-Faria tributary basin. Further, food and chemical industries predominate, in terms of number as well as BOD loads, corresponding, to 55 to 59% of the total pollution loads from all factories. Table 4.2-4 ranks the industries in terms of contribution of BOD.

Fig. 4.2-2 presents, schematically, the discharge of industrial BOD loads into the tributary basins. The Niteroi and Sao Goncalo regions, where there is a conglomeration of seafood producers, constitute the greatest BOD load contributors in the Guanabara basin, followed by the Rio Timbo-Faria and Rio Iguacu tributaries.

Fig. 4.2-3 compares industry and domestic BOD loads flowing into each tributary basin to demonstrate the point source pollution distribution. Domestic loads were estimated, based on the population of each tributary basin (1991), multiplied by 50g BOD/cap./day.

The Sao Joao de Meriti and Sarapui basins generate relatively large BOD loads composed, only 10 and 5% of industrial source. This situation is totally different to the Niteroi and Sao Goncalo tributaries, where industrial sources are almost 1.8 times greater.

In the Rio Timbo-Faria basin, also, industrial BOD is discharged in appreciable amounts.

The explanation mentioned above concerns only organic loads. According to FEEMA data, approximately 75 factories in the metal finishing are mainly responsible for 362 kg of heavy metals.

Finally, FEEMA plans to improve oil control efficiency, including, almost 2000 gasoline stands that constitute one of the most important pollution sources.

Table 4.2-1 Chronogram of the Industrial Control
