2000	4,086	41	
2001	4,252	43	
2002	4,426	44	
2003	4,606	46	
2004	4,794	48	
2005	4,990	50	

The existing number of employees, although deviating greatly from LWUA's Methodology Manual is deemed justified. The location and facilities of the TC-WD especially the booster pumping stations are in remote areas necessitating three(3) shifts of operators/pump tenders.

1

However, upon completion of the project in 1997, a reduction in the number of employees will be necessary in as much as the newly constructed pumping station is a single stage.

(2) Cost for Operation and Maintenance of the Water Supply System

A summary of operation and maintenance cost for the Tagaytay water supply system is shown in **Table 11.5-3**, and a breakdown of the expenditures is presented in **Table 11.5-4a** to **11.5-4c**.

11.5.3 Financial Analysis

(1) Financial Background

Tagaytay Water District was established in May, 1975. From 1984 to 1986, the district received the grant at the total amount of 12 million pesos from the central government to improve its water supply facilities.

(2) Development Cost

The cost estimates of the required improvements are presented in the preceding section. A breakdown of the project cost on an annual basis is shown in **Table 11.5-5**.

(3) Operating and Maintenance Costs

Operating and maintenance costs are shown in **Table 11.5-6**. Details are also shown in the preceding section (Section 11.5.2).

(4) Project Financing

100% of the total project cost is assumed to be financed by loans. The district shall be exempted from the equity contribution since it has not received major loan from LWUA. Computation of the loan is shown below.

TABLE 11.5-3 SUMMARY OF OPERATION AND MAINTENANCE COST TAGAYTAY WATER DISTRICT

	SALARIES POWER & FUEL CHEMICALS MISC. & MAINTENANCE	ESCALATED TOTAL O & M COST

Note:
For financial analysis, operation and maintenance cost in 1994 is mainly based on the financial statements of the district although large parts are projected. Therefore, it is not necessarily equal to the costs shown in Table 11.5-3 through 11.5-4.

Total Project Cost 67.24 million pesos
Capitalized Interest 12.22 million pesos
Total Loan Amount

(regular and soft loan) 79.46 million pesos

50% of the loan is assumed to be at regular loan with interest rates of 8.5%, 10.5% and 12.5% for the first 2 million pesos, the next 5 million pesos and the excess of 7 million pesos, respectively.

Remaining 50% of the loan is to be a soft loan with the terms and conditions described in Section 11.1-3.

The details of the project loan's debt service schedule is presented in Table 11.5-7.

(5) Projection of Financial Statements

The water district's projected income statement for the period 1994–2005, as presented in **Table 11.5-8**, shows that annual net income are positive except in 1995 and 1997. Major financial ratios derived from the income statement shows as follows;

- a) Operating ratio which measures the ability of revenues to cover operating expenses shows that the operating costs are between 66 74% of the operating revenues after the project completion.
- b) Return on the average fixed assets, which measures the earning power of the district's facilities, ranges from 11 to 19% after the completion of the project.

The projected cash flow statement for the same period as shown in Table 11.5-9 indicates the sources and applications of funds. Major highlights from this table are as follows:

- a) Increase in working capital is positive throughout the study period except in 1995.
- b) Debt service coverage which shows the ability of the district's internal cash generation to meet its debt services vary between 2.0 and 3.2 in 1999 2005. These ratios are higher than LWUA's minimum ratio of 1.3.

The projected balance sheet are presented in **Table 11.5-10**. Major points are shown as follows;

- a) Cash balance at the end of the study period (2005) is 42.6 million pesos.
- b) A total of 44.1 million pesos is accumulated for cash reserves by the year 2005.
- c) Current ratios which measure the ability of the district to meet its short term obligations increase from 5.0 in 1998 to 8.4 in 2005.

as The ratio which total current assets divided by the total current liability

Definity minus total current liability)

d) Debt/equity ratios which indicate the percentage of the long-term debt in the net worth decrease gradually from 74% in 1998 to 46% in 2005.

(6) Financial Internal Rate of Return

As shown in **Table 11.5-11**, the FIRR is 23.7 percent for the base case. The derived FIRR is well above the water district's weighted average cost of capital at 12.1 percent, which is shown in **Table 11.5-12**.

(7) Sensitivity Analysis

A sensitivity analysis is conducted to determine the effect of variances in the assumptions to the FIRR. The derived FIRR under selected variances to the base case are as follows:

<u>Scenario</u>	<u>FIRR</u>
Base Case	23.7%
1. 20% increase in Investment Cost	20.3%
2. 20% increase in O & M Cost	18.9%
3. 20% decrease in Revenue	13.8%

The computation of the FIRR under the different scenarios is also shown in Table 11.5-11. Results of the sensitivity analysis shows that the FIRR is greatly influenced by the decrease of revenue. The derived FIRR, however, are still more than the water district's weighted average cost of capital.

(8) Recommended Water Rates

The recommended water rates are shown below. The rates are proposed to increase annually up to 2005. The details including water rates over 40 m³ are also presented in Table 11.5-8.

	<u>Minimum</u>	11-20m ³	21-30m ³	31-40m ³
1994	110.00	5.80	7.05	9.05
1996	131.89	6.95	8.45	10.85
1998	160.31	8.45	10.27	13.19
2000	193.98	10.23	12.43	15.96
2002	226.18	11.93	14.50	18.61
2005	269.38	14.20	17.26	22.16

These recommended water rates are subject to the following criteria:

- a) Minimum charge (First 10 m³) must not exceed 5% of the average family income of the low income group
- b) Any increase must be limited to 60% of the prevailing rates.

The 1996 volume of cu.m. is deducted from the water demand projections annually throughout the study period for the incremental volume. Price per cu.m. was based on the de-escalated average rate per cu.m. of water. Economic value per cu.m. was assumed to be 1.2 times the price per cu.m. of water.

TOTAL INCREASE IN CONSUMER SATISFACTION

As can be seen in **Table 11.5-8**, the recommended rates for the first 10 m³ do not exceed 5% of the average income of the low income group. Also, all rate increases are within the maximum limit of 60%.

(9) Concluding Remarks of Financial Analysis

The proposed development program for Tagaytay Water District is financially viable. However, it must be emphasized that the following conditions should be fulfilled.

- a) Water rates as discussed above should be adopted and attained.
- b) The project should be implemented in 1996 and completed by the end of 1997.
- c) The targeted number of service connections should be attained because the FIRR is the most sensitive in the revenue reduction.

Since the recommended water rates are almost 5% of the average income of the low income group continuously from 1995 to 2001, the adoption of the progressive water rates system, with an increase of rates as the consumption of water increase, may be taken into consideration more clearly. Then, the minimum charge will be in a fully affordable range of the low income group.

11.5.4 Economic Analysis

(1) Project Benefits

Consumer Satisfaction

Under the assumption described in Section 11.1.4, the present economic value of water at 15% discount rate is 56.1 million pesos as shown in **Table 11.5-13**.

Health Benefits

Morbidity rate of water-born disease in Tagaytay City is 917 out of 100,000 according to the Municipal Socio-economic Profile. When 125 pesos per day and 8 days per patient were lost by illness, the present economic value of health benefits at 15% discount rate is 0.35 million pesos as shown in **Table 11.5-14**.

Fire Protection

Udder the assumption described in Section 11.1.4, the present economic value of fire protection at 15% discount rate is 2.3 million pesos as shown in **Table 11.5-15**.

Description of the second of th

The April of the American

TABLE 11.5-15 REDUCTION IN FIRE DAMAGE - Tagaylay Water District

Population in the service area was derived from the Population and Demand projections.

The number of structures was estimated by dividing the service area population by the average number of persons per dwelling unit of 5.2. The total value is estimated by multiplying the number of structures with the average replacement value of dwelling units in Tagaytay of 250,000 peacos.

Percentage fire protection was based on the area to be served by fire hydrants. ≈ 12 ⊏

(2) Project Costs

The detail of the conversion of financial project cost to economic cost is shown in **Table 11.5-16**. Further, incremental economic operation and maintenance cost is shown in **Table 11.5-17**. The summary of economic costs including the total replacement cost of 7.5 million pesos are shown in **Table 11.5-18**.

(3) Economic Benefits and Costs Analysis

The summary of quantifiable economic benefits and economic costs for the project is shown below expressed as net present values of a 15% discount rate. Benefit cost ratio (BCR) obtained is 1.01. Salvage value is shown in Table 11.5-20.

Increase in Consumer Satisfaction	56.05 million pesos
Health Benefits	0.35 million pesos
Reduction in Fire Damage	2.32 million pesos
Total Benefits	
(Salvage value is not included.)	58.72 million pesos
Total Project Costs	58.46 million pesos
Benefit Cost ratio (BCR):	1.01

(4) Economic Internal Rate of Return

The results of EIRR are summarized below. EIRR for base case is estimated at 15.2%. Details are shown in **Table 11.5-19**. A sensitivity analysis is conducted to determine the effect of variances in the assumptions to the EIRR. The derived EIRR under selected variances to the base case are as follows:

<u>Scenario</u>	EIRR -
Base Case	15.2%
1. 20% increase in Investment Cost	12.7%
2. 20% increase in O & M Cost	14.6%
3. 20% decrease in Revenue	11.3%

The result show all the scenario except base case can not exceed the opportunity cost of capital of 15%.

(5) Concluding Remarks of Economic Analysis

From the results of the preceding analysis, the proposed project for Tagaytay Water District is considered economically almost feasible although the results of sensitivity analysis are below the opportunity cost of capital.

SALVAGE VALUE		18,426			474			2,381	21,281
ADD: LAND TOTAL SALVAGE VALUE									5,152

The increase in land value as an economic benefit due to the provision of an improved water supply system was not estimated for this analysis since by NEDA it is not advisable to add the benefit in the economic feasibility study on the water supply project. This is mainly because it is difficult to isolate the benefits brought about by the improvement of the water supply system from other factors.

In Tagaytay such as other major tourism spot in the country, however, the benefit may be added with the careful market survey of the land value for commercial and tourism facilities in particular because the value seems to be large. Then, the EIRR may reach more feasible range.

11.6 PROJECT FOR TANZA

11.6.1 Estimation of the Construction Cost and Construction Period

(1) Construction Cost

The basic construction costs of the Phase I improvement for the Tanza water supply facilities totals P8.21 million, while the Phase II totals P21.16 million.

A summary of the estimated project cost is presented in Table 11.6-1a and 11.6-1b, and the detailed breakdown is shown in Table 11.6-2a and 11.6-2b.

(2) Construction Period

In accordance with the facility requirements as described in Section 10.6.6, the construction period is presented in Fig. 11.6-1.

11.6.2 Organization and Cost for Operation and Maintenance of the Water Supply System

(1) Organization

The TAN-WD presently has 6 employees headed by the general manager. However, it will be required to increase this number in 1997 after the proposed water supply system is implemented.

Based on the number of service connection described in Section 10.6.4, the number of personnel for the TAN-WD from the year 1995 up to 2005 is computed as follows:

_	Design year	No. of Connection	No. of Employee	
	1995	809	8	
	1996	1,365	14

(2) Cost for Operation and Maintenance of the Water Supply System

A summary of the operation and maintenance costs for the Tanza water supply system are shown in Table 11.6-3, and a breakdown of the expenditures is presented in Table 11.6-4a to 11.6-4c.

For the financial analysis in Section 11.6.3, a summary of operation and maintenance cost and a breakdown of the expenditures for Phase I only are presented in **Table 11.6-5**, and **Table 11.6-6a** to **11.6-6c**, respectively.

11.6.3 Financial Analysis

(1) Financial Background

Tanza Water District was established in 1988. The district has implemented the approved loan of 12 million pesos from 1991 to 1994 for the development of its water system which consist of drilling of a deep well, pipe laying of transmission and distribution lines, reservoir construction and provision for disinfecting of the water served. The district was exempted from the equity contribution since the project was their initial major improvement.

(2) Development Cost

The cost estimates of the required improvements are presented in the preceding section. A breakdown of the project cost on an annual basis is shown in Table 11.6-7.

(3) Operating and Maintenance Costs

Operating and maintenance costs are shown in **Table 11.6-8**. Details are also shown in the preceding section (Section 11.6.2).

ESCALATED TOTAL O & M COST	289	1,059	1,991	3,015	4,509	5.411	6,448	7,647	8.831	10,045	11,413	13,124

Note:
For financial analysis, operation and maintenance cost in 1994 is mainly based on the financial statements of the district although large parts are projected. Therefore, it is not necessarily equal to the costs shown in Table 11.6-3 through 11.6-6.

(4) Project Financing

90% of the total project cost is assumed to be financed by loans. It is assumed that the district will prepare 10% of the their own equity portion in the total project cost since the project is their second major improvement. Computation of the loan is shown below.

Į.

Total Project Cost (Phase 1)	10.63	million pesos
Water District Equity	1.06	million pesos
Capitalized Interest	1.96	million pesos
Total Loan Amount	•	
(regular and soft loan)	11.53	million pesos

Seventy percent (70%) of the loan is assumed to be at regular loan with the condition that interest rate of 12.5% is applied to all the amount of the regular loan.

Remaining 30% of the loan is to be a soft loan with the terms and conditions described in Section 11.1.3. The share of regular loan and soft loan is based on the experiences of the first improvement program in 1991–1994.

The details of the project loan's debt service schedule is presented in Table 11.6-9.

(5) Projection of Financial Statements

The water district's projected income statement for the period 1994–2005, as presented in **Table 11.6-10**, shows that annual net income are positive. Major financial ratios derived from the income statement shows the following;

- a) Operating ratio which measures the ability of revenues to cover operating expenses shows that the operating costs are between 55 - 68% of the operating revenues after the project completion.
- b) Return on the average fixed assets, which measures the earning power of the district's facilities, ranges from 13 to 20% after the completion of the project.

The projected cash flow statement for the same period as shown in **Table 11.6-11** indicates the sources and applications of funds. Major highlights from this table are as follows:

- a) Increase in working capital is positive throughout the study period except in 1995.
- b) Debt service coverage which shows the ability of the district's internal cash generation to meet its debt services varies between 1.7 and 2.3 from 1999 to 2005. These ratios are higher than LWUA's minimum ratio of 1.3.

The projected balance sheet are presented in **Table 11.6-12**. Major points are shown as follows;

Total data to the second secon												

a/ The ratio which total current assets divided by the total current liability
b/ Long-term debt as a percentage of the net worth (total liability) and equity minus total current liability)

- a) Cash balance at the end of the study period (2005) is 10.5 million pesos.
- b) A total of 10.4 million pesos is accumulated for cash reserves by the year 2005.
- c) Current ratios which measure the ability of the district to meet its short term obligations increase from 2.1 to 4.4 after the project completion.
- d) Debt/equity ratios which indicate the percentage of the long-term debt in the net worth decrease from 82% in 1998 to 51% in 2005.

(6) Financial Internal Rate of Return

As shown in Table 11.6-13, the FIRR is 28.5 percent for the base case. The derived FIRR is well above the water district's weighted average cost of capital at 12.0 percent, which is shown in Table 11.6-14.

(7) Sensitivity Analysis

A sensitivity analysis is conducted to determine the effect of variances in the assumptions to the FIRR. The derived FIRR under selected variances to the base case are as follows:

<u>Scenario</u>	<u>FIRR</u>
Base Case	28.5%
1. 20% increase in Investment Cost	24.1%
2. 20% increase in O & M Cost	18.8%
3. 20% decrease in Revenue	12.3%

The computation of the FIRR under the different scenarios is also shown in **Table 11.6–13**. Results of the sensitivity analysis shows that the FIRR is greatly influenced by the decrease of revenue. The derived FIRR, however, are still more than the water district's weighted average cost of capital.

(8) Recommended Water Rates

The recommended water rates are shown below. The high increase of the rates in 1995 and 1998 are tallied with the full implementation by the Program of Work and the projected implementation in this project although almost bi-annual increase up to 2005 is also proposed. The details are also presented in **Table 11.6-10**.

	Minimum	$11-20m^3$	21-30m ³	Over 31m ³
1994	60.00	6.00	6.20	6.35
1996	101.79	10.18	10.52	10.77
1998	127.24	12.72	13.15	13.47
2000	139.96	14.00	14.46	14.81
2002	153.96	15.40	15.91	16.29

The 1996 volume of cu.m. is deducted from the water demand projections annually throughout the study period for the incremental volume.

Price per cu.m. was based on the de-escalated average rate per cu.m. of water. Economic value per cu.m. was assumed to be 1.2 times the price per cu.m. of water.

× € €

186.29

These recommended water rates are subject to the following criteria:

- Minimum charge (First 10 m³) must not exceed 5% of the average family income of a) the low income group
- Any increase must be limited to 60% of the prevailing rates. b)

As can be seen in Table 11.6-10, the recommended rates for the first 10 m³ do not exceed 5% of the average income of the low income group. Also, all rate increases are within the maximum limit of 60%.

(9) Concluding Remarks of Financial Analysis

The proposed development program for Tanza Water District is financially viable. However, it must be emphasized that the following conditions should be fulfilled.

- Water rates as discussed above should be adopted and attained. a)
- The project should be implemented in 1996 and completed by the end of 1997. b)
- The targeted number of service connections should be attained because the FIRR is the c) most sensitive in the revenue reduction.

11,6,4 Economic Analysis

Project Benefits (1)

Consumer Satisfaction

Under the assumptions described in Section 11.1.4, the present economic value of water at 15% discount rate is 20.2 million pesos as shown in Table 11.6-15.

Health Benefits

Morbidity rate of water-born disease in Tanza is 342 out of 100,000 according to the Municipal Socio-economic Profile. When 120 pesos per day and 8 days per patient were lost by illness, the present economic value of health benefits at 15% discount rate is 0.07 million pesos as shown in Table 11.6-16.

Fire Protection

Under the assumption described in Section 11.1.4, the present economic value of fire protection at 15% discount rate is 8.8 million pesos as shown in **Table 11.6-17**.

(2) Project Costs

The detail of the conversion of financial project cost to economic cost is shown in **Table 11.6–18**. Further, incremental economic operation and maintenance cost is shown in **Table 11.6–19**. The summary of economic costs including the total replacement cost of 2.2 million pesos are shown in **Table 11.6–20**.

(3) Economic Benefits and Costs Analysis

The summary of quantifiable economic benefits and economic costs for the project is shown below expressed as net present values of a 15% discount rate. Benefit cost ratio (BCR) obtained is 1.58. Salvage value is shown in **Table 11.6-22**.

Increase in Consumer Satisfaction	20.18	million pesos
Health Benefits	0.07	million pesos
Reduction in Fire Damage	8.84	million pesos
Total Benefits		
(Salvage value is not included.)	29.09	million pesos
Total Project Costs	18.49	million pesos
Benefit Cost ratio (BCR):		1.58

(4) Economic Internal Rate of Return

The results of EIRR are summarized below. EIRR for base case is estimated at 34.4%. Details are shown in **Table 11.6-21**. A sensitivity analysis is conducted to determine the effect of variances in the assumptions to the EIRR. The derived EIRR under selected variances to the base case are as follows:

Scenario	<u>EIRR</u>
Base Case	34.4%
1. 20% increase in Investment Cost	29.0%
2. 20% increase in O & M Cost	31.0%
3. 20% decrease in Revenue	24.3%

For all the scenarios, the EIRR exceed the opportunity cost of capital of 15%.

	DEDITOTION	N EIDE DAMAGE				53 633		2000

Population in the service area was derived from the Population and Demand projections.

The number of structures was estimated by dividing the service area population by the average number of persons per dwelling unit of 5.2.

The total value is estimated by multiplying the number of structures with the average replacement value of dwelling units in Tanza of 200.000 peacos.

Percentage fire protection was based on the area to be served by fire hydrants.

(5) Concluding Remarks of Economic Analysis

From the results of the preceding analysis, the proposed project for Tanza Water District is considered economically feasible.

CHAPTER 12 ENVIRONMENTAL IMPACT ASSESSMENT OF THE WATER SUPPLY PROJECTS

CHAPTER 12

ENVIRONMENTAL IMPACT ASSESSMENT OF THE WATER SUPPLY PROJECTS

Although the advantage or positive impacts of the water supply projects are great, some adverse impacts have to be taken into consideration.

<u>G.M.A project</u> would contribute to the general increase of groundwater level drawdown in the area. Therefore, groundwater monitoring and management is suggested in this Study.

<u>Mendez project</u> concerns not only with the groundwater condition around the proposed wells, but also with the groundwater and/or spring conditions downstream of the project site. Therefore, the spring discharges should also be monitored together with the groundwater level.

<u>Tanza</u> and <u>Naic projects</u> face the same problem of saline water intrusion. Therefore, the monitoring of water quality and groundwater level should be conducted to provide basic data for pumpage control.

<u>Tagaytay project</u> has no direct impacts on groundwater. However, deforestation accompanying with development as an tourism zone should be restricted and wastewater treatment facilities should be improved to prevent reduction and deterioration of groundwater in lower elevation areas.

12.1 ENVIRONMENTAL IMPACT ASSESSMENT FOR G.M.A.

G.M.A. is located in the eastern part of the Study Area, at the boundary of groundwater flowing and storage areas. Generally, groundwater development potential in such a hydrogeological condition like in G.M.A. can be considered as relatively good. However, in spite of its relatively small area, G.M.A. has the highest level of urbanization and industrialization in the Study Area. The population density of G.M.A. is as high as 70.34 persons/ha, which is about 12.5 times the average in the Study Area. G.M.A. has also the highest industrial water consumption intensity (1598 m³/y/ha), which corresponds to 26.7 times the average in the Study Area.

Therefore, out of the 5 F/S areas, G.M.A. has the highest water utility intensity and consequently shows the largest groundwater level drawdown rate (1.57 – 2.55 m/year) during the past 10 years. This means that groundwater extraction in G.M.A. has, at least partially, exceeded the groundwater development potential.

It is projected that the water demands of G.M.A. WD for the years 2000 and 2005 will be about 2.43 times and 2.96 times that of 1994. On the other hand, the water supply facility survey revealed that the future water demand will exceed the capacity of the present facilities. Therefore, new water resources have to be developed and new facilities have to be designed and constructed to meet the needs of water supply for the well-being of the population. Furthermore, the results of groundwater simulation in Chapter 5 indicated that with the projected water demand, the groundwater level would decline by one (1) to two (2) meters per year in the G.M.A. area.

As discussed in Chapter 10, no water resources other than groundwater can be used practically and economically for domestic water supply in G.M.A. at present and in the near future. The G.M.A. project of groundwater development is critical from the viewpoint of groundwater conservation, but indispensable from the viewpoint of human livelihood and health, which is the most essential factor in environmental assessment.

General items regarding the impact of groundwater development project on the environment have been discussed in Chapter 9. Thus, only items that needs particular emphasis will be discussed here.

Since G.M.A. has nearly reached and/or partially exceeded its limit for groundwater development at present, there is a serious concern that any future tapping of groundwater will cause more serious groundwater level drawdown and even groundwater depletion.

For the purpose of groundwater conservation, the following monitoring/management (M/M) plan should be formulated:

(1) Establishment of Groundwater Monitoring System

Abandoned and operational wells can be used to establish a groundwater monitoring network. Proper spatial distribution should be taken into account.

(2) Ground Water Level Observation

Ground water levels should be observed monthly as part of the operation and maintenance program of the water district. All the observation records should be made available to LWUA for arrangement and encoding to the database.

Groundwater quality should also be monitored periodically.

(3) Analysis and Evaluation

Observations encoded in the database shall be input to the groundwater flow model installed at LWUA for evaluation of the existing and future groundwater conditions.

(4) Groundwater Management Options

Results of the evaluation shall be the basis for making groundwater management policies or decisions for the water district.

In addition to the proposed Groundwater Management Committee in Chapter 9, a Technical Subcommittee should be formed, which could be composed of LWUA personnel, to do the evaluation on the existing and future groundwater conditions using the groundwater flow model. Like the MWSS for its service area, the water district then should be deputized by NWRB to investigate water rights application for groundwater exploitation in their district. In consultation

with the Technical Subcommittee, the water district sets the volume of water (and also the screen positions) that can be exploited based on the results of the evaluation.

Serious campaign to save water should be done. People should be made to understand that they have no choice but save water since no alternative source of water is available. Facts regarding groundwater usage such as records of groundwater pumpage and water levels must be disclosed to the people to enhance users awareness to save water. When the time comes that LWUA is confident on the reliability and accuracy of the groundwater model, the results and recommendations of the simulation must be publicized so that the people and the government could respond to the problem quickly.

Future land use plan of the province in general and each municipality in particular should be reviewed and revised if needed from the viewpoint of groundwater potential.

For the purpose of avoiding groundwater pollution, a safe distance should be maintained from the wells to prevent admission. Especially in G.M.A., many industrial effluent and a lot of domestic wastewater constitute a very high pollution threat to groundwater.

From ocular survey, it seems hard to meet the demand for a safe distance, as in the case of JICA test well and most G.M.A. WD wells. Therefore, measures should be taken, such as providing cement grout deep enough to avoid the infiltration of pollutants into the wells.

12.2 ENVIRONMENTAL IMPACT ASSESSMENT FOR MENDEZ

Mendez is located upland in the recharge area of the groundwater basin of the Study Area. Existing groundwater levels range from 50 m to 100 m below ground surface. The recharge area of Mendez itself is small. The groundwater development potential in Mendez is low, as shown in the Groundwater Evaluation Map. On the other hand, Mendez has the highest level of urbanization with the highest population density among the upland municipalities.

The water demands of Mendez WD for the years 2000 and 2005 are estimated to be 1.7 times and 3.3 times that of 1994. On the other hand, the water facility survey reported that the future water demand will exceed the capacity of the present facilities. On this account, new water resources have to be developed and new facilities have to be designed and constructed to meet the water needs for the well-being of the people.

Since most headwaters of springs lie in Mendez, no surface water potential can be taken into consideration. The only possible water resources at present although limited is groundwater. Thus, the Mendez project of groundwater development is indispensable from the viewpoint of people's livelihood and health.

Three (3) alternatives are discussed in Chapter 10, and alternative 1 is recommended for its cheaper cost. This alternative seems to be the best one from the viewpoint of environment conservation,

because the wells and other construction items proposed in this alternative are the fewest and, consequently, its impact will be relatively small.

The most serious impact of the Mendez project seems to be that groundwater development will cause decrease in groundwater level and perhaps in the discharge of springs located downstream of the wells.

For the purpose of groundwater conservation, the M/M plan for Mendez project should have the same content as that for G.M.A. project. Besides the Mendez WD wells, springs around the project site, especially those springs located downstream of the wells, should also be monitored.

12.3 ENVIRONMENTAL IMPACT ASSESSMENT FOR NAIC

Naic is located in the northern lowland of the Study Area, facing the Manila Bay. As part of the groundwater storage area, a relatively high groundwater development potential can be expected in Naic.

Naic is largely an agricultural area with 60 percent of its population residing in the rural area. Therefore, the water consumption intensity for domestic and industrial purpose is relatively low.

The water demands of Naic WD for the years 2000 and 2005 are projected to be about 3.5 times and 11.2 times that of 1994. On the other hand, the water supply facility survey revealed that the future water demand will exceed the capacity of the present facilities. Therefore, new water resources have to be developed, and new facilities have to be designed and constructed to meet the water needs for the well-being of the people.

Though Naic lies in the lowland area where several rivers are flowing, the surface water can hardly be used for drinking purposes, because it requires a complex and high cost water treatment system. Therefore, the proposed groundwater development project is indispensable from the viewpoint of human livelihood and health.

Naic WD uses spring water as its present water source and has no groundwater development facilities such as pumping station, storage tank and disinfection facilities, except several kilometers of transmission/distribution lines. According to the survey, another spring can not be used to increase the supply amount. Therefore, groundwater development is indispensable, and supplementary facilities such as disinfection facilities are needed.

Of the four (4) alternatives presented in Chapter 10, alternative 4 is recommended for its lower cost. This can be recommended also from the viewpoint of environment conservation. More facilities like wells and tanks are proposed in alternative 4 and this is unfavorable for groundwater quality protection. However, the most serious factor in this project is the threat of saline water intrusion.

Well No.1, which is included in all the four (4) alternatives, has the largest designed discharge and is the nearest to the coastline among the proposed wells. Therefore, a large drawdown in

groundwater level can be expected, and consequently, saline water intrusion may occur. In fact, the appearance of saline water intrusion has been released by EC observation in EIA survey.

Furthermore, the results of groundwater simulation in Chapter 5 indicated that with the projected water demand, the groundwater level would decline by 5 to 10 meters in 10 years (1995–2005) in Naic area.

However, if alternative 4 were adopted, two (2) other wells will be located at a safe distance from Well No.1. Therefore, it is possible to decrease the pumping discharge of each well, which will consequently contribute to minimize groundwater level lowering. This should be given an important consideration in the coastal area in order to prevent saline water intrusion.

For the purpose of groundwater conservation, a M/M plan similar to that of G.M.A. is necessary. Besides groundwater level, groundwater quality should be given enough attention in the monitoring, specifically, Na, K, Cl, Ca, TDS and EC.

12.4 ENVIRONMENTAL IMPACT ASSESSMENT FOR TAGAYTAY

Tagaytay City is located in the highest portion of the Study Area and is considered as a recharge area for groundwater. Since the city is famous for its mild climate and beautiful landscape, Tagaytay is planned as a tourist center.

The water demands of Tagaytay WD for the years 2000 and 2005 are forecasted to be about 1.74 times and 2.3 times that of 1994. On the other hand, the water supply facility survey revealed that the future water demand will exceed the capacity of the present facilities. Therefore, additional water resources have to be developed, and new facilities have to be designed and constructed to meet the domestic water demands.

Because of its high elevation, existing groundwater level is more than 100 m below the ground surface, and since recharge is scarce, any production well will inevitably cause a rapid and serious drawdown of groundwater water level. Accordingly, almost no groundwater can be developed practically.

The present water sources of the city water supply are three (3) springs with discharge enough to meet the water demand in the year 2005. Thus, increasing spring water utility may be the most reasonable option to adopt for the present and in near future.

Since it differs from the other projects, which are all designed for groundwater development, the Tagaytay project has no direct impact on groundwater.

The two (2) alternatives presented in chapter 10, however, show no obvious difference from the viewpoint of environment conservation.

Because the landscape is a more sensitive factor in Tagaytay City than in any other areas of the Study Area and the project involves the construction of pumping stations and about 4 kms of pipeline, these facilities must be in harmony with the landscape.

Moreover, deforestation accompanying with development as an tourism Zone should be restricted and wastewater treatment facilities should be improved to prevent reduction and deterioration of groundwater in lower elevation areas.

12.5 ENVIRONMENTAL IMPACT ASSESSMENT FOR TANZA

Tanza is also a lowland municipality located in the vicinity of Naic and exhibits the same geological and topographical characteristics of Naic.

The water demands of Tanza WD for the years 2000 and 2005 are projected to be about 12.9 times and 24.4 times that of 1994. On the other hand, the water supply facility survey showed that the future water demand will exceed the capacity of the present facilities. Therefore, new water resources have to be developed, and new facilities have to be designed and constructed to meet the domestic water demands.

Like Naic, Tanza can not use its surface water resources for domestic purposes.

Three (3) alternatives are presented in chapter 10, and alternative 1 seems to be the most environmentally suitable one, requiring relatively fewer facilities (wells and storage). Besides, all these facilities are relatively far from the coast; consequently, there will be less concern with regards to saline water intrusion. However, it is the most expensive (about 1.7 times more than alternative 2 and 1.3 times more than alternative 3). Perhaps, alternative 2 is a more reasonable option at the moment.

The results of groundwater simulation in Chapter 5 indicated that with the projected water demand, the groundwater level would decline by 10 to 40 meters in 10 years (1995–2005) in Tanza area towards Noveleta, and a groundwater level depression of 50 meters below MSL near the coast will occur in the middle and lower aquifers at its boundary with Noveleta. This depression will cause saline water intrusion especially in the area between the coastline and the center of depression. For the rest of the Tanza area, no danger of saline water intrusion is expected unless the depression moves inland.

The M/M plan for Tanza should be formulated similar to that of Naic.

CHAPTER 13 CONCLUSIONS AND RECOMMENDATIONS

CHAPTER 13

CONCLUSIONS AND RECOMMENDATIONS

As shown in Fig. 13.1, the Study Area is divided into four (4) sub-areas from the view point of groundwater potential and future water demand (year 2005).

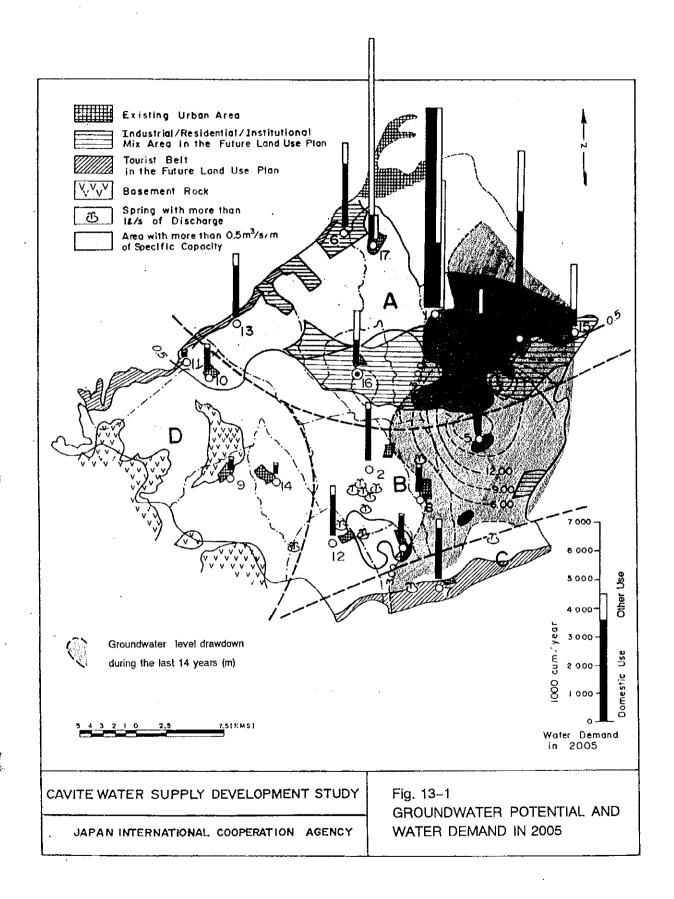

Sub-area A which comprises Dasmarinas, G.M.A., Tanza, Naic, Carmona as well as parts of Silang and Trece Martirez covers the low elevation area. Though groundwater potential is comparatively high, the projected water demand is also large since the area is rapidly developing as an Industrial/Residential/Institutional Mix Zone. As mentioned earlier, groundwater level drawdown and saline water intrusion are in progress in Sub-area A. According to the results of groundwater simulation, these phenomena shall be accelerated drastically, considering the projected water demand. Consequently, permissive yield (or permissive critical water level) should be decided for Sub-area A, and monitoring of groundwater level and water quality is vital and should be conducted. It is also necessary to re-examine the existing development plans and to establish measures to control the use of groundwater by industries and secure its use for domestic.

Sub-area B which comprises Mendez, Tagaytay, Amadeo, Alfonso as well as the southern part of Silang covers the middle to high elevation area. Though groundwater potential is low in Sub-area B, the projected water demand is not as large as that of Sub-area A since its designated land use is agribusiness and tree crops zone. It is desirable therefore to maintain its present land use and use groundwater sustainably since Sub-area B is part of the recharge area of the groundwater basin and it has many springs which are at present valuable domestic water sources.

<u>Sub-area C</u> which comprises Tagaytay and the southern part of Alfonso covers the highest elevation area. Groundwater development is difficult in this area not only because groundwater potential is low, but also groundwater level is deep. Springs on Tagaytay cliff, however, have been utilized as domestic water sources because of its large discharge. Still they have plenty of discharge to be developed to meet future water demand if the consumers are willing to pay a high water rate equivalent to the operation and maintenance cost. When this area is developed as a tourist zone, it is necessary to preserve forest and improve wastewater treatment facilities, because Sub-area C is part of the recharge area of the groundwater basin.

<u>Sub-area D</u> which comprises Magallanes, Maragondon, Ternate and Gen. Aguinaldo covers the western end of the Study Area. The groundwater potential of this area is low since the basement rocks crop out widely. But the future water demand is also low because the development of this area as predicted will be left behind mainly due to insufficient road network. Thus, the groundwater development in Sub-area D has no special problem with regards to the conditions of the projected water demand.

As mentioned above, pumping control is necessary for Sub-areas A and C monitoring pumping discharge and groundwater level. Four measures recommended in Section 9.5, which are (1) Establishment of the priority of groundwater use, (2) Establishment of groundwater management

committee, (3) Examination of permissive pumping discharge, (4) Re-examination of regional development plan and land use plan, should be implemented for sustainable use of groundwater, which is a valuable water resource in the Study Area.

Feasibility studies of water supply projects for the urban areas of G.M.A., Mendez, Naic, Tagaytay and Tanza were conducted on the assumptions that the measures recommended would be implemented. The essence of the projects are summarized in Table 13-1.

ANNEX

<ANNEX>

EXPLANATION OF HYDROGEOLOGICAL MAP OF CAVITE PROVINCE

1. Objective of Hydrogeological Map

The "Hydrogeological Map of Cavite Province" was made based on various hydrogeological data collected in the "Cavite Water Supply Development Study".

This map is expected to be revised when new data are collected since the data used in the preparation of this map are not always accurate.

2. Climatic and Topographical Conditions (Lower left of No.1)

Isohyet lines show the average annual precipitation calculated from the observed data at five PAGASA stations in the Study Area and its vicinity. Observation period is from 1984 to 1993. Colors show the difference of elevation divided at every 200 m. It clarifies the relationship between precipitation and elevation: the higher the elevation, the more precipitation.

3. Administrative Unit Map (Upper left of No.1)

Administrative boundaries shown in this map are based on the map "PROVINCE OF CAVITE (1/50,000)" published by NAMRIA in 1990.

4. Hydrogeological Map (Center of No.1)

Various hydrogeological information as well as information on topography, survey points, administrative boundaries, watershed boundaries and road network are included in this map.

The topographical information was extracted from the topographical map published by NAMRIA in 1990 with a scale of 1/50,000, and the road network information was extracted from the map prepared by DPWH (REGION-4A).

As for the survey point information, the location of four test wells drilled during the Study, the survey lines of geophysical prospecting, the hydrological observation points, and the existing wells (registered in PGDB:105, not registered in PGDB:62) are entered.

As for the hydrogeological information, the distribution pattern of each stratigraphic formation, faults and other geostructural elements, contours of groundwater table, and top surface contours of Talisay formation are entered.

Contours of groundwater table were drawn using the data obtained from the simultaneous groundwater level measurement in twenty (20) deep wells and the static

water level of existing 167 wells. The top surface contours of Talisay formation means the top surface of Lower aquifer which is distributed over the whole Study Area, and the groundwater stored above this aquifer flows along this plane.

5. Groundwater Resource Potential Map (Upper left of No.2)

This map shows the distribution pattern of specific capacity (Sc), which were obtained from the data of existing wells and the four test wells drilled in the Study. The specific capacity shown in this map does not mean the specific capacity of the same aquifer, but it indicates the groundwater potential in the Study Area in a broader sense.

In this map, a high specific capacity zone with more than 2.0 l/s/m is around Tanza. It is known that several thick conglomerate layers are distributed in this area, forming a good aquifer.

6. Hydrogeological Cross Sections (Lower right of No.2)

Two geological cross sections in east-west and north-south directions and three sections using the data obtained from the geophysical prospecting survey are shown. The Upper, Middle and Lower aquifers can be identified in these sections.

7. Results of Water Quality Analysis (Upper right of No.2)

The results of analysis for spring water (10 samples), river water (15 samples) and deep well water (20 samples) collected in dry and wet seasons of 1994 are plotted on the key-diagram and the map. These figures tell that the water quality changes in proportion to the storing time.
