

(5) **Review about IDC**

For hydropower project, interest during construction makes significant influence for increasing the total project cost. In this study, IDC is calculated for the project by the following manner.

$$IDC = 0.4 \times R \times T \times \text{Investment Cost}$$

where, R ; rate of interest
T ; Construction Term (year)

In this review, above equation is checked to be appropriate or not in Viet Nam, using data of Son La project studied in "Pre-F/S". In this report, construction term of the project is considered to be 14 years, and yearly progress ratio by investment cost is shown in Table 6.2-11.

Supposing that yearly interest ratio is equal to 10%, and that investment cost is equal to 100, calculated IDC based on yearly disbursement schedule becomes 58 as shown in that table.

If IDC is under same condition, that is R=10%, and T=14 years, by above equation, it is calculated by the above equation as follows;

$$IDC = 0.4 \times 0.1 \times 14 \times 100 = 56$$

Therefore, it can be appreciated to estimate IDC by the above equation.

6.2.3 **Assessment of Hydropower Projects**

(1) **Scope of Assessment**

Assessment of hydropower projects is made based on the planned figures submitted by IEV (PIDC1) and result of JICA Study Team's review described in 6.2.2.

In this section, the assessment is made by employing several indexes, those are "B/C" and "Levelized Unit Energy Cost".

However, the following should be kept in mind as the initial condition for making assessment of hydropower projects;

- (a) In the calculation, the benefits for other sector/s such as flood control, irrigation, etc. of the multipurpose projects have not been considered, so that the project cost has not been allocated to other sector/s, and the power sector has to bear all the project cost, except several projects ordered by IEV.
- (b) For the calculation of benefit, electricity is quoted from 6.2.2 for the reviewed project. For other projects, electricity offered by IEV as shown in Table 6.2-1 is applied.
- (c) In assessment of the new hydropower projects and Power Development Planning Study in chapter 8, investment costs offered by IEV are applied. Among the new projects, IEV notified JICA Study Team, that the investment cost of Ban Mai

project, Dong Nai 4 project, and Dai Ninh project should be changed to figures which they offered.

- (d) According to IEV, part of power discharge of Dai Ninh project reviewed in 6.2.2 is not used for power generation, but irrigation. Though influence to projects downstream is not changed, annual energy of Dai Ninh project becomes different. As there is no information about this matter, annual output for assessment is quoted from the figure shown in Table 6.2-1 for Dai Ninh project, that is 1,218 GWh generated by the project itself, and 1,175 GWh, considering the influence to energy production of Tri Anh hydropower plant downstream.

(2) **Basic Concept of Assessment**

Assessment described here is to evaluate hydropower project from economic aspect. One of the economic evaluations of a hydropower project is made based on the benefit-cost analysis comparing its cost with that of an alternative thermal power project with the equivalent power supply functions. In this study, annual benefit and equalized annual cost is adopted for evaluation. These matters are described later. Also the hydropower projects are evaluated by levelized unit energy cost (US\$/kWh).

A coal thermal power project is adopted, because coal can be supplied economically and stably in Viet Nam, comparing with oil, natural gas, and other fuel materials as described in 3.5.

(3) **Equalized Annual Cost**

The equalized annual cost of a hydropower project consists of depreciation and operation-maintenance (OM) cost. This is estimated by multiplying the annual cost factor by the investment cost assuming a discount rate of 10% and the following conditions;

- Service Life:

| | |
|-----------------------------|----------|
| Civil Facility | 50 years |
| Hydro-mechanical Facility | 25 years |
| Electro-mechanical Facility | 25 years |

- Rate of Operation and Maintenance Cost to Direct Project Cost:

| | |
|-----------------------------|------|
| Civil Facility | 1.5% |
| Hydro-mechanical Facility | 1.5% |
| Electro-mechanical Facility | 1.5% |

The method of calculation of equalized annual cost is shown in Appendix 6.2.6.

(4) **Levelized Unit Energy Cost**

Using equalized annual cost and results of electricity calculation in 6.2.2 or electricity shown in Table 6.2-1, "Levelized Unit Energy Cost" is also calculated by next equation. IDC is considered here as described in 6.2.2.

Levelized Unit Energy Cost = Equalized Annual Cost x (1 + 0.4 x R x T) / Annual Energy

(5) **Annual Benefit**

The annual benefit of hydropower projects is provided according to the cost of the alternative thermal power project composed of capital cost, OM cost and fuel cost. Those costs are divided into fixed cost and variable cost, and converted to unit kW and unit kWh cost at the receiving end of power and energy. The figures are shown in Table 6.2-12.

The annual benefit of hydropower project is obtained by next equation.

$$\text{Annual Benefit} = \text{kW value} \times \text{Pf} \times 24 / \text{Tp} + \text{kWh value} \times \text{E}$$

where, Pf: Firm capacity (MW)
Tp: Peak Operation time (hour)
E: Annual Output (kWh)

In this matter, benefit of hydropower project varies depending on "Tp". In this study, "Tp" is basically assumed to be 8 hours to evaluate capacity value of hydropower.

For some projects, however, value of "Pf x 24/Tp" becomes larger than installed capacity of the project, if "Tp" is shortened. In this case, therefore, peak firm capacity, that is the value of "Pf x 24/Tp", is set with limitation of installed capacity in the calculation of annual benefit. Here, firm capacity is defined as the capacity which can be supplied more than 95% of the calculation term.

(6) **Results of Assessment**

Using the method described as clauses (1)~(5), hydropower projects are evaluated economically by "B/C" and "Levelized Unit Energy Cost".

(a) **Results of the projects along the Da river, the Sesan river, and the Dong Nai river**

The results of the assessment of reviewed projects in case of peak operation of 24 hours and 8 hours are shown in Table 6.2-13. Comparing the values in this table, findings of the assessment are as follows;

In the assessment of hydropower project by "B/C", kW value makes large influence in B/C value. B/C can be larger by employing shorter peak time. If peak time operation is not considered, that means "24" hour peak operation, the projects of which B/C is larger than 1.0 are only Son La (L), Plei Krong and Sesan 3 projects.

If peak operation time is supposed to be 8 hours, B/C of almost all the projects become larger than 1.0. Even in this case, however, B/C of Dong Nai 8 is less than 1.0.

Compared with B/C of three river systems, that of the Da river systems is highest. Though B/C of the Dong Nai river systems is the lowest, projects along the Dong Nai river systems could be developed not only as important hydropower resource in Southern region, but also multi-purpose project to make effective use of water resource.

For individual projects along these three river systems, Son La, Huoi Quang, Thuong Kontum, Plei Krong, and Sesan 3 project can be highly appreciated.

For the Dong Nai river basin, Dai Ninh project can be highly appreciated.

(b) Comparative Study about the Da river basin development scheme

There are two alternatives for the Da river development scheme in this study. Compared with two alternatives, combination of Son La (S) and Huoi Quang scheme is highly appreciated in levelized unit energy cost. But compared by B/C value, Son La (L) scheme is highly appreciated in 24 hours peak operation, and Son La (S) and Huoi Quang scheme is highly appreciated in 8 hours peak operation as shown in Table 6.2-13. So, B/C value of these two alternatives are compared by varying peak operation time, those are 24, 12, 10, 8, 6 hours. The results are shown in Table 6.2-14 and Figure 6.2-3.

These data shows that Son La (L) scheme is highly appreciated under the condition of more than 10 hours peak operation, and Son La (S) and Huoi Quang scheme is highly appreciated under the condition of less than 10 hours peak time operation.

Considering above matter, Son La (L) project supplies power mainly for base demand, and Son La (S) and Huoi Quang scheme can be oriented to a power supply mainly for peak demand. Role of the project in electricity demand and load curve after the commissioning year should be taken into consideration to determine the development scale of Son La project. This matter is studied in Power Development Planning Study in chapter 8.

(c) Assessment of Individual New Hydropower Projects

Assessment of individual new hydropower projects is made, using the same method described above. The result of study in 24, 12, 10, 8, 6 hours peak operations are shown in Table 6.2-15. In the table, electricity values are quoted from Table 6.2-1 for the projects not reviewed in 6.2.2. Rankings of the projects under varying peak operation time and levelized energy unit cost are shown in Table 6.2-16. Besides this study, individual projects are assessed by using reviewed investment cost. The results are shown in Appendix 6.2.7.

Findings of the study are as follows:

The projects of which B/C is larger than 1.0 under 24 hour peak time operation are Sesan 3, Ban Mai, Son La (L), and Plei Krong projects. If studied by reviewed investment cost, B/C of Ban Mai project becomes less than 1.0. These projects can be highly appreciated as hydropower energy generator.

Considered by peak operation, B/C of all the projects except Dong Nai 8 and Can Don project becomes larger than 1.0. But B/C of Cua Dat and Song Con 2 projects also becomes less than 1, using reviewed investment cost.

By shortening peak operation hour, B/C of Thuong Kontum and Dai Ninh project becomes larger, and ranked as high class. This shows that these projects are suitable mainly for power supply for peak electricity demands. But ranking becomes lower, if considering reviewed investment cost.

By shortening peak operation hours, B/C of Son La (L) and Plei Krong projects are ranked lower. It is because the ratio between firm capacity and installed capacity is so high that peak firm capacity, that means firm capacity multiplied by "24/Tp" becomes larger than installed capacity by shortening peak operation hours, and benefit by kW is limited.

As shown in Table 6.2-16, levelized unit energy cost of Ham Thuan/Da Mi project is 0.0524 US\$/kWh. Considering this fact, projects ranked less than Song Con 2 in Table 6.2-16 seem to be expensive in levelized unit energy cost. Projects of which levelized unit energy cost is less than 0.0600 US\$/kWh, that is a kind of criterion of levelized unit energy cost, are recommendable to be developed. But eight projects are considered to be expensive, in the condition with JICA Team's reviewed cost, as shown in Appendix 6.2.7.

Son La, Huoi Quang, Sesan 3, Dai Thi, and Ban Mai projects are ranked in higher class than Ham Thuan & Da Mi project in Table 6.2-16. They can be highly appreciated as promising projects. But, considered with JICA Team's reviewed investment cost, Ban Mai project is ranked lower.

(7) Conclusion

Considered in Viet Nam as the whole area, projects along the Da river and Dai Thi projects are highly appreciated in Northern region. In Central region, projects along the Sesan river are highly appreciated. In Southern region, Dai Ninh project can be highly appreciated under peak operation as the next project to be developed after Ham Thuan/Da Mi project. For these projects, collecting basic data is necessary for further study.

As shown in Table 6.2-16, Son La, Huoi Quang, Dai Thi, and Sesan 3 projects are confirmed to be promising projects.

Among 4 projects, Sesan 3 project is now studied only at the desk level. Also, there are five projects planned in the Sesan river basin including Yaly project under construction. Therefore, master plan study along the Sesan river basin will be necessary at first, before it's F/S. But master planning study should be started as soon as possible to make sure of promising project and development scale, because Sesan 3 project which is ranked first in the ranking table, is expected to be commissioned after 2002 and before 2010 by IEV.

For Dai Thi project, F/S will be necessary. But Dai Thi project is not expected to be commissioned until 2010 by IEV. According to IEV, it is multipurpose project. Therefore, the following matters should be studied, besides general technical matters;

- (a) Amount of monthly or daily water supplying plan
- (b) Distribution of effective volume of reservoir for each purpose, for example, irrigation, energy generation, flood control, etc.
- (c) Reservoir operation rule with water supply

Pre-F/S of Son La project along the Da river has already been finished by PIDC-1. First generating unit of Son La project is expected to be commissioned in 2007 by IEV. Considering the construction schedule, construction work should be started at least by the beginning of 2000's. And F/S and definite design work should be finished before construction work. Therefore, F/S should be started as soon as possible.

Considering above matters, F/S of Son La project should be promoted positively, if official development assistance for Viet Nam in energy sector is considered to be made.

In F/S, determining the development scale is one of the basic problems for Son La project. According to the study in this section, Son La (S) project (2400MW) is confirmed to be suitable mainly for a power supply for peak demands, and Son La (L) project (3600MW) is confirmed to be suitable mainly for a power supply for base demands. Development scale will be selected as a result of this stage of study, by the result of optimum power development planning study described in chapter 8.

For the purpose of F/S on Son La project, items to be confirmed are summarized in Appendix 6.2.8. Additionally, comments on Son La project are described in next section.

(8) Comments on Son La Project

Since the Son La project is planned with a range of installed capacity of 2,400 MW to 3600 MW, and, therefore, has significant impact on power system development of Viet Nam, general description of the Son La hydropower project is given below to clarify its present status for the purpose of the study.

The development plan of Son La project was established in 1978. "General Report on the Multipurpose Use of the Da River" approved by the Vietnamese government specifies the exploitation of Da River by two hydropower projects, the Hoa Binh hydropower plant with a normal reservoir level of 115 m in the 1st stage and Son La (Ta Bu Site) with a normal reservoir level of 260 m estimated in the 2nd stage.

After that, the pre-F/S was implemented by PIDC1 and approved by the government in 1992. The pre-feasibility report clearly shows the concept of the project and findings to be cleared in the F/S. The report shows the study on 3 cases of the project scale depending on the high water level of the reservoir, large scale with EL 265 m, middle scale with EL 240 m and small scale with EL 215 m. Four candidate dam sites of the project are proposed for each case. But technical matters on site selection and development are not described in detail in the report.

Four candidate dam sites of the reservoir are called Pa Vinh, Ta Bu, Ban Pau, and Ban Ta from upstream. For Son La project, dam is considered to be constructed at Ban Ta site by PIDC-1. But elevation level of Ban Ta site is lower than High Water Level of Hoa Binh reservoir downstream. Therefore, High Water Level of Hoa Binh reservoir will be set lower by 20 ~ 30 m during construction of Son La project. In this case, energy of Hoa Binh hydropower plant will be decreased by 40~50%, considering the effective head of Hoa Binh hydropower plant. This matter should be taken into consideration in the study of dam site selection and optimum development scale study. Geological information about Son La project is shown in Appendix 6.2.9.

Sedimentation is now one of the big problems at the Da river systems. According to IEV, sedimentation level of Hoa Binh reservoir back water becomes almost the same as the planned level after impounding of Hoa Binh reservoir by only a few years. Unfortunately, these data were not offered by IEV. For Hoa Binh project, sedimentation was estimated with the method of former USSR. Sedimentary inflow might have been estimated lower than the actual sediment inflow. This matter should be reviewed in detail in F/S. This is an important factor for determining Low Water Level of reservoir of Son La project, and can make some influence for development scale.

For rockfill dam construction, materials for embankment were also studied. In pre-F/S report by PIDC-1, however, borrow area for soil materials and quarry site for rock materials are not described. In F/S, location of borrow area and quarry should be studied.

at first. And amount of embankment materials of each borrow area or quarry should be estimated taking quantities of embankment and type of dam into consideration.

Because of the long term of required construction period, construction plan and schedule is important aspect for project economy.

Environmental issues are a concern because of the wide area at High Water Level of Son La project, those are 275 km² in Son La (S) project, and 508 km² for Son La (L) project. As recommended in the pre-F/S report, the north-western part is constituted by flat terraces with elevation of about 230~240 m. These areas will be under High Water Level of reservoir in case of Son La (L) project, that is 265m at present. The small scale development of the project is preferable from environmental view point. Avoiding the resettlement of too many people and wishes of minority people to conserve their old lands are taken into consideration in environmental impact assessment of the project.

Table 6.2-1 Specification of Hydro Power Projects

| Project Name | Unit | The Northern Region | | | | | | The Center Region | | | | | | | | | | The Southern Region | | | | | | | |
|------------------|--------------------|--------------------------------|------------|------------|---------|---------|---------|-------------------|-------------|-----------|--------|------------|---------|---------|---------------|-----------|----------|---------------------|-----------|-------|------------|------------|---------|----------|-------|

Chapter 7 REVIEW AND ASSESSMENT OF ENERGY RESOURCES FOR POWER GENERATION

7.1 Assessment of Availability of Energy Resources until the Year of 2010

7.1.1 Coal Resource Availability

Coal reserves in Viet Nam for thermal power generation are more than enough. At least, coal reserves theoretically fulfill the demand. In northern Viet Nam, Quang Ninh province, there are 3.1 billion tons of anthracite reserves, which is the total of surveyed reserves (A+B+C1+C2), to the depth of 300m. Total reserves of anthracite and semi-anthracite to the depth of 1,000 m are said to be 6.6 billion tons. Usually, when the development of a coal mine is being decided, coal reserves of A, B and half of C1 will be counted as recoverable. Among the surveyed reserves of coal, anthracite mineable reserves are 557 million tons (Refer to Table 7.1-1).

In Viet Nam, there are other coal reserves beside anthracite, 11.8 million tons of bituminous and 244.1 million tons of lignite and semi-bituminous of surveyed reserves category. Especially in the lower part of the Red-river, under the depth of 700m, there are about 20 billion tons of lignite reserves. However these estimated reserves of lignite are not yet proved, nor technically and economically possible to be exploited.

Coal reserves in Viet Nam are concentrated in her northern part, especially in Quang Ninh province, and anthracite reserves which are 92% of all kinds of total coal reserves lie in Quang Ninh province, about 3 billion tons or 97% of its total reserves. Among the northern coal reserves of 557 million tons mineable reserves, 538.5 million tons are in Quang Ninh province. There are three coal production areas; Uong Bi, Hong Gai and Cam Pha, in the north-east of Hai Phong in the province. There are four main coal sedimentary basins of these three and Bac Thai. In these basins or areas, there are the same names of the coal companies and they are exploring and extracting coal. There is 300 km coal belt area in northern part of Viet Nam, which makes possible the development of thermal power plants in north, but in middle and southern parts of the country coal production and supply to the thermal generation site will be rather high cost.

Coal quality in Viet Nam is good, although there are differences in each coal of coal mines. All of them are high heating value, low sulfur content and considerable small ash content. Adequate quality of coal for thermal power generation does not require high level of heating value. At present, No.8 and No.9 of Vietnamese category coal are supplied, and No.5 and No.4B coal of 4,000 - 5,000 Kcal/kg of low heating value will be supplied in future (Refer to Table 7.1-2).

Today, coal supply to the Pha Lai thermal power plant is from Uong Bi Coal; Mao Khe and Vang Danh mines, recoverable reserves of which are 91 million and 37.4 million tons each, and will be enough to supply for the future coal requirement. For the Pha Lai thermal power, coal supply from Hong Gai and Cam Pha Coal companies will be added, especially from Coc Sau mine of Cam Pha Coal; open pit mine of 25.4 million tons of recoverable reserves, is enough to exploit with its existing facilities. At the Cam Pha Coal, there are other mines which will be possible to supply coal in future.

Production capacity (designed capacity) of 4 state coal companies in Viet Nam are like as follows at present.

| | |
|--------------------------|--|
| Cam Pha Coal Co. | 5,750,000 tons (Raw Coal) 4,300,000 tons (Clean Coal) |
| Hong Gai Coal Co. | 1,900,000 tons (R. C.) 1,600,000 tons (C. C.) |
| Uong Bi Coal Co. | 1,250,000 tons (R. C.) 1,000,000 tons (C. C.) |
| Domestic (No.3) Coal Co. | 1,510,000 tons (R. C.) 1,180,000 tons (C. C.) |

There are several forecasts of coal demand for the thermal power plants in Viet Nam. According to the forecast prepared by the Institute of Energy, Viet Nam, coal demand for the thermal power plants in Viet Nam in 1994 is 500 thousand tons and it will increase 900 thousand tons in 1995, 1.7 million tons in 1996, 2.3 million tons in 1997, 2.4 million tons in 1998, 2.5 million tons in 1999 and 3.2 million tons in 2000, in the average case. There is another forecast of the coal demand for thermal power plants in the year of 2010; 4.8 - 6 million tons. In this average forecast case, total production of coal is 7.5 million tons in 2000 and 12 - 15 million tons in 2010, among which 42.7% and 40% will be supplied to the thermal power generation demand. Toward the above coal demand, the possible coal supply will be from the above state coal companies, especially Cam Pha Coal company will be the biggest supplier. However, this average forecast case consists rather low demand of coal for other industry except electricity and cement industries, where coal demand decreases one third from 1994 to 2000. Total demand of coal in Viet Nam will be more and the high case of this forecast may be adequate one. At this high case of forecast, total production of coal in 2000 is set at 10 million tons, and it will be necessary to finance the required investment to this supply capacity of coal in coal companies (Refer to Table 7.1-3 and 7.1-4)

Summing up the demand and supply of coal to the thermal power generation;

- (1) Initial coal reserves in Viet Nam are enough to fulfill the coal demand under the current production plan in long term.
- (2) Present coal production capacity of Viet Nam; 10 million tons of raw coal and 8 million tons of clean coal a year, will be possible to extract coal 8 million tons till 1997, with the productivity increase of coal mines.
- (3) For the coal supply above 8 million tons of demand after 1998, new investment for coal production facilities is necessary.
- (4) For the coal production and supply after 2000, new mine development and transportation facilities and others are essentially needed, and the investment for this should be in early stage and with large amount.
- (5) Among the total coal production, thermal electricity coal demand and supply will be the largest, always, and electricity industry should be the protector to the coal industry especially on the coal price issue.

7.1.2 Natural Gas Resource Availability

(1) Forecast based on the Ultimate Recoverable Reserves

Oil and Gas exploration activity in on-land and off-shore Viet Nam is in an early stage of its history and the evaluation work of hydrocarbon reserves in various sedimentary basins in Viet Nam is not yet attained. Exploration work is at present concentrately carried out in Cuu Long and Nam Con Son basins southern off-shore from Ho Chi Minh city and probably is in its highest time in 1994 and 95. The state oil and gas company, Petro Viet Nam (here-in after referred PVN) had signed numbers of production sharing contracts with foreign oil companies, and they had carried out geophysical surveys in their contracted areas, discovered more than 300 structures after the analysis of processed data, drilled more than 70 exploration wells. However, it is rather difficult to estimate the ultimate recoverable reserves of hydrocarbon in exploration untouched sedimentary basin areas. Nevertheless, the ultimate recoverable reserves of oil and gas in all the sedimentary basins in Viet Nam is estimated at approximately 4 to 5 billion tons (30-37 billion barrels) in oil equivalent. Geologists are in tendency to conservatively evaluate resources, and this reserve estimation will be increased according to the exploration progress and supply of new geological data.

Natural gas ultimate recoverable reserves are estimated at 600-700 billion m³, among all the hydrocarbon reserves. This figure is calculated from the above mentioned hydrocarbon reserves adopting with GOR (gas oil ratio) of 170, namely 170 m³ of gas per one ton of oil.

Among the natural gas ultimate recoverable reserves of 600-700 billion m³, only 100 billion m³ are so far discovered. These reserve figures are natural gas from oil fields (associated gas) and from gas fields (non-associated gas). These figures will probably increase rapidly as the exploration activity progresses. So far, oil fields were discovered in Cuu Long basin and oil and gas fields were discovered in Nam Con Son basin. Numbers of these discovered fields are already developed or being developing. It can be said that there are gas prominent sedimentary basins in off-shore Viet Nam. Especially in Danang Basin in off-shore mid-Viet Nam, huge gas reserves were discovered while this gas contains large amount of carbon dioxide (CO₂) and is not economically possible to develop and produce gas. In the Red-river basin in northern Viet Nam, there should be more exploration work aiming a gas discovery, and in Minh Hai basin of off-shore area of southwest, adjacent to the Cambodian and Malaysian boundary ocean area, large gas fields are expected to be discovered (Refer to Figure 7.1-1).

There is a close relationship between exploration progress and the shifting of the possible ultimate recoverable reserves to the proved reserves. And oil and gas discovery degree will be parallel with exploration speed. Exploration activity in off-shore Viet Nam is still in burgeoning stage in the large areas of sedimentary basins. Exploration is concentrated in the above mentioned two basins, and there is quite a lot of work of geophysical survey or exploration drilling in other basins. Therefore the available data to estimate the ultimate recoverable reserves in sedimentary basins is deviated, and the accurate evaluation of all the hydrocarbon in offshore Viet Nam is almost impossible to proceed at present. Nevertheless, with reviewing of the past ten years exploration results econometrically, there will be no doubt an estimation of another 100 billion m³ of natural gas discovery in the coming ten years.

Natural gas discovery is watched in numbers of oil and gas fields in off-shore Viet Nam, and there are the associated gas in Cuu Long basin and non-associated gas in Nam Con Son basin. There are fields of under-evaluation of reserves with drilling of confirmation wells. Therefore, there are another 100-150 billion m³ of estimated reserves in these fields, and if we add it to the above discovered reserves, the total reserves can be said between 200 to 250 billion m³ in the discovered fields. With the drilling of confirmation wells, the accuracy of reserves is increasing and the reserve category of oil or gas will shift to the more accurate part. In the Vietnamese category which resembles the Russian one; A, B, C1, C2, D1 and D2, there will be more A and B shifted from C1 and C2.

(2) Discovery of Oil and Gas Fields and Natural Gas Supply

In Viet Nam, associated gas from Bach Ho oil field is being flared and burnt uselessly at present, at the oil production spot of Vietsovetro had been planned to deliver to a thermal power plant inland as fuels with lying of off-shore gas pipeline. This 100 km pipeline from the field to inland near Vung Tau was nearly completed in October, 1994 and a gas processing plant and on-shore pipeline are under construction at present by the company, and probably gas will be delivered to Ba Ria thermal power plant within 1995. It will be the first time for huge gas utilization in Viet Nam of the Bach Ho associated gas use at the power plant.

Ba Ria thermal power plant will consume natural gas about 280 million m³ annually while Bach Ho oil field's flared gas is 1,200 million m³ and it will be enough to supply at present. Together with Bach Ho field, Rong oil and gas field lying south-west of Bach Ho field, is also in the development stage and gas of Rong field both associated and non-associated will be supplied in future with connection of a pipeline. The ultimate recoverable reserves of associated gas in Bach Ho field are confirmed as 20 billion m³, and Rong field gas is 5 billion m³ (Refer to Table 7.1-5).

The associated gas from both fields will be supplied also to Thu Duc thermal power plant north-east of Ho Chi Minh city and the inland pipeline lying for this supply of about 100 km is also accelerated. Thu Duc thermal power plant will consume about 300 million m³ of gas annually. Other gas utilization of this flared gas is planned such as LPG manufacturing plant and chemical fertilizer factory. Gas sending capacity of this pipeline will be 1,200 million m³ annually in initial stage, while the associated gas of Bach Ho field will be used as fuels on site of production, and as materials of the tertiary recovery of oil; gas lift method, in future.

Among the 20 billion m³ of Bach Ho associated gas, total 4.7 billion m³ of gas had been already flared and burnt at the end of 1994. Therefore there is 15.3 billion m³ of remaining recoverable gas at this field. If we add the Rong field gas of 5 billion m³ to this, 20.3 billion m³ of gas is available which is theoretically only 17 years availability supporting the supply and consumption of 1.2 billion m³ annually. Moreover, if the replacing of fuels of oil to gas at thermal power plants, especially such change in Thu Duc plant will not be realized in early time, the amount of flared gas uselessly by burning will be increased. When we expect long time gas supply, these two fields gas supply seem to be clearly not enough. Because of the associated gas production which is determined by the production of oil, it will not be possible to get 1.2 billion m³ of gas constantly with these two fields when the oil fields production declined.

It was reported that the peak production year of Bach Ho oil field is 1995. Therefore, the associated gas of this field will be also in production peak in 1995, and then it declines.

The ultimate recoverable reserves of this field are 117 million tons of oil and 20 billion m³ of gas. In Figure 7.1-2 (a), there are both oil and gas production declining curves, which accelerate after 2000 year, but gas production declining curve is rather moderate compared with oil production declining, due to that, after oil production comes to an end, gas reserves will still remain and continue production.

Bach Ho field gas production declining will be partly substituted by Rong field gas, but not completely. In Figure 7.1-2 (a), there are production forecast curves of additional gas supplied by fields beside the above two fields; Case A means the associated gas production from the nearby oil field, Case B (Figure 7.1-2(b)) means non-associated gas production. The supplying of 1.2 ~ 1.5 billion m³ yearly of associated gas is not enough and non-associated gas production is essential. Especially after 2000, non-associated gas production will increase rapidly and will reach 6 billion m³ production in 2010, half of which is BP/Statoil's production from their 2 gas fields.

Among the so far discovered oil or gas fields in off-shore Viet Nam, the field in which can fulfill supplying gas to Bach Ho field's declining is said to be Dai Hung field 100 km south from Bach Ho. However, this field's recoverable reserves were cleared rather smaller than originally estimated, after drilling of confirmation wells and determination of the structure. Associated gas of this field initially estimated as large with oil reserves of 500 - 600 million barrels, but it comes to a smaller amount as oil reserve estimations have shrunk to only 150 million barrels at present. Taking the GOR of 160, Dai Hung gas is estimated at about 3.2 billion m³ of ultimate recoverable reserves which is smaller than Rong field gas reserves. Dai Hung field started its oil production in October, 1994, with early production facility and associated gas produced with oil burnt on site. The nearest oil field to Bach Ho field so far discovered is Rang Dong oil field in Mitsubishi oil company's contracted area but the delineation work of this field is in ahead and actual reserves are not yet determined. However, it is reported that the GOR of this field is rather high and the associated gas reserves are large. Petronas Carigali of Malaysia discovered Jade and Ruby fields in their contracted block, north-east of Bach Ho field, but details of these discoveries are not yet reported because of lack of data.

Gas reserves are expected to be found in Nam Con Son basin which lies south of Cuu Long basin where Bach Ho field is situated. In Nam Con Son basin, beside the above mentioned Dai Hung field, two gas fields were discovered by the British Petroleum/Statoil group (Refer to Figure 7.1-3).

This group of companies drilled three wells of exploration in 1993 to 94 and discovered Lan Tay and Lan Do gas fields. The structures of these fields are rather large and it can be estimated that the reserves of gas combining both fields is approximately 2-3 TCF (60 - 90 billion m³). The British Petroleum Co., officially declared that reserves of these two fields was 2 TCF, in September, 1994. BP/Statoil group wishes to commercialize these two gas field discoveries associated with other company gas discoveries in nearby areas, because these offshore areas are rather deep water and distance from the shore is 270 km and the field's development cost is rather large. Companies engaged in exploration in these areas are jointly planning to lie another pipeline to the shore, 300 km totally, to send gas to onshore, but this plan is not yet finalized.

Natural gas supply in southern Viet Nam thermal power plants will be limited if it depends on only associated gas of oil fields. It is doubtful which field will be a supplier of gas when Bach Ho field associated gas declines its production except Rong field. The associated gas of Rang Dong field is the most expected one, but it will be decided by the result of future exploration work. Gas supply from Bach Ho and Rong fields will be

declined to rather low levels in 10 years time and it is desired to discover and develop other will decline large fields in Cuu Long basin promptly.

It will be most important issue to develop gas fields discovered by BP/Statoil in Nam Con Son basin, together with the development of other company gas discoveries near by their fields, and to lie a new joint pipeline system. For this development work of natural gas supply, at least US\$3/MMBTU should be approved and then gas production of 3~6 billion m³ per year will be realized.

7.1.3 Petroleum Product Availability

Fuel oil consumption in thermal power plants in Viet Nam is not so large amount at present. Fuel oil used in thermal power plants such as Ba Ria in south Viet Nam is planned to to be replaced by natural gas in the future. In the remote area, where transmission line of electricity is not approached, diesel oil burning generation plant will be used. Heavy fuel oil co-burning at the coal fired power plants will continue but the demand forecast of these fuel oils is rather difficult. However it is estimated that the present consumption level of fuel oil will continue without much change; such as 700,000 tons of petroleum products to the thermal power plants a year, nearly half and half of heavy fuel oil and diesel oil.

It is rather easy to acquire these amounts of fuel oil from outside of the country, and companies in Singapore and Malaysia supplied fuel oil to Viet Nam. In future, Viet Nam will have her own petroleum refinery in the country and supply petroleum products domestically. PVN decided to build a refinery at Van Phong near Vung Tau, by the joint venture with CFP Total Co., of France and CPC of Taiwan and others. Refining capacity of this refinery is 6.5 million tons a year (130,000 BPSD) and it will be completed and commence production in 1999, with estimated construction cost of 1 - 1.3 billion dollars. This refinery will be filled with crude oil, Vietnamese produced at, Bach Ho and other fields, but a part of crude oil will be Middle Eastern crude. Vietnamese low sulfur crude oil can be sold at high price and Middle Eastern lower price crude of the refinery use attains high merit of economic value.

Beside the above refinery project, PVN plans to build another one or two refineries in future. All of these are in planning stage and the details of these, especially availability of fuel oil products, are not yet confirmed. Therefore, it is unknown at present how much petroleum products can be supplied domestically, but if 700,000 tons of fuel oil annually continue on the demand side, petroleum product to thermal power plants can be supplied without difficulty. However, in the year 2010, if thermal power plants replace their gas fuel to petroleum products in case of lacking of gas supply with production hintage, domestic fuel oil supply may become short and fuel oil imports will revive again.

7.2 Technical and Economic Assessment of Energy Resources

7.2.1 Assessment of Coal Resources

There are several important issues on the assessment of technical and economical matters of availability of coal resources in Viet Nam.

First of all on coal reserves, even if there are enough coal reserves in Viet Nam to fulfill thermal power plants in coming decade, when we make long term forecast of demand and supply, these present proved reserves of coal can not be said to be completely enough. Coal exploration activity to determine proved reserves in Viet Nam in the last few years had tremendously decreased. The state four coal companies carried their coal exploration, stratigraphic well drilling in 1993, only 8,348 m which is one sixth of 10 years ago in 1984, 50,997 m. Other exploration work of the companies may be also declining even if data is not available. In the year 1993, 19,530 m of stratigraphic drilling had been planned but it was not achieved because of lack of investment found for exploration. This situation makes coal availability for thermal plants indefinite in 21st century. In the exploration planning, stratigraphic drilling in the year 2000 is expected 45,000 m and in 2005 it is designed 35,000 - 40,000 m, but it is doubtful if it can be achieved or not (Refer to Table 7.2-1).

Recoverable reserves of coal (anthracite) in Viet Nam are at present 557 million tons and this runs 111 years of coal supply in the level of production of 5 million tons a year. However, coal is expected to increase production; 10 million tons in 2000, 15 - 20 million tons in 2010. In such case, cumulative production amount till 2010 will be 170 - 200 million tons. Therefore, the remaining recoverable reserves is still more than 300 million tons in 2010 and there will be enough recoverable reserves according to the calculation of these factors. However, this production forecast of coal is rather moderate and if coal will exploit 40 - 50 million tons a year, this present proved reserves continue only 11 to 14 years. It will be impossible to establish such huge production systems promptly, however, if thermal power plants will be expanded rapidly and if huge natural gas supplies are be attained, establishment of large coal supply systems in Viet Nam will become the most necessary factor. For this purpose, exploration of coal to add new recoverable reserves is essentially needed.

Next issue is the timeworn of coal production facilities in Viet Nam and delaying of its rehabilitation of old facilities. It is needless to say on the actual situation of old production facilities of each mine relates to production decline and rising costs. For this rehabilitation it is necessary to invest tremendous amounts of capital or funds, while the financial situation of coal companies deteriorated and their new investment amounts decreased. Among the rehabilitation of coal facilities, coal clean facilities are the most important. Old cleaning coal unit of No.1 site of Cam Pha Coal, Hong Gai Coal, and out of dated facility of Uong Bi Coal are necessary to renew, then the additional value of coal will be increased and economically improved. Unless there will not be a revolutionary investment increase on coal development, production, loading, shipping and transportation facilities, coal production in Viet Nam will continue only at the current low level of production till 2000 with present old facilities, but after 2000 year there will be a tight situation of coal supply.

Coal investment plans have been made by companies, for each five years from 1991 to 2005, by two separate programs (Refer to Table 7.2-2). Total investment amount in 15 years is 3 trillion Dong (\$280 million) in the first plan and 4.1 trillion Dong (\$380 million) in the second plan, which is 20 - 30 million dollars investment program every year. In this investment plan, coal production facilities investment for Phu My thermal power plant is not included (in case the fuel for this power plant in future will be changed from natural gas to coal), and investment for the related infrastructure is also not summed up. However, the actual investment in the last few years was recorded at a far less amount than this program and should there be some sort of improvement, the present situation will

be renewed. For the healthy development of coal industry, 40 - 60 million dollars yearly investment is necessary, and for the improvement of financial situation of coal companies, the raise in mine head coal prices and introduction of foreign investment in Vietnamese coal production should be necessary. Coal delivery prices were raised several times, but the present coal price in Viet Nam is still far lower than international price. Foreign coal companies also joined Vietnamese coal industry contracting the Production Sharing with state coal company, e.g an Indonesian firm's case, but there should be more foreign investment. However, the most important issue on coal companies investment program is strong support of the state with supplying domestic or foreign bank loans, and so on.

7.2.2 Assessment of Natural Gas Resources

The most important issue of technical and economic assessment on natural gas development and production is the establishment of resource reserves. The potential reserves of natural gas in Viet Nam are large, and it is estimated about 600 - 700 billion m³ as stated in former page. The point at issue is the exploration of oil and gas and establishment of proven gas reserves.

The state oil company, PVA had offered off-shore oil exploration rights to foreign oil companies in international bidding and signed the Production Sharing contracts. There are nearly 30 PS contracts and the exploration work was carried out being by foreign oil companies with their risk bearing (Refer to Figure 7.2-1).

In the exploration procedure, oil companies aim to find oil and gas, with priority of finding oil and then finding gas subsequently. In case of Drill Stem Test (DST) of oil and gas during the exploration drilling, oil testing is presently carried out and even if there is a gas zone in the strata, gas testing will be the secondary case. On the PS contracted block of oil companies, there will be only several exploration wells drilled by the obligation clause and oil companies will withdraw from the contract area if their discovery is a marginal one, unless they find a large accumulation of oil or gas. Several oil companies have already withdrawn from off-shore Viet Nam or firmed out their contract rights to other companies.

Petroleum exploration technology is advanced day by day and the re-opened block to foreign oil companies where the former oil companies withdrew because of unsuccessful exploration work, may be a hopeful block. The new comer may be a finder of oil or gas with new technology or by new geological knowledge. The discovery of Rang Dong oil field by Mitsubishi Oil Co., is one such case, as their block was formerly explored by Deminex company of Germany and abandoned as not promising.

It is widely recognized that either the vast area of sedimentary basins is determined as rich oil and gas bearing area or not, there should be more than 200 exploration wells drilled. In off-shore Viet Nam, there are so far only 70-80 wells having been drilled and it is too early to determine such a definition. Therefore when three times more wells are drilled such a situation will be recognized. With taking the above mentioned fact, will sign more PS contracts with foreign oil companies in future or the company contract terms may be amended, the exploration work will be continued.

Oil or gas fields in Viet Nam; Bach Ho field being the most prominent, are known as geologically specialized fields where the oil accumulation is in fracture of basement rock (Refer to Figure 7.2-2 and 7.2-3).

This is an oil field named by Chinese of "Old Buried Mountain" or in English, "Buried Hill" type of field. Special features of this type of oil field are the difficulty of determination of the size of

structures (in this case, fracture or cave) by analyzing work of the records of seismic survey and indefiniteness of reserve confirmation. Another specialty is that production of oil will be initially very large for several years but it will decline drastically in the subsequent years. Bach Ho field is a large one in such type of oil fields, and is producing large amounts of oil and gas, however its peak production will be in 1995 and then it will follow the declining curve of production. Rang Dong field is also a "Buried Hill" type and it is necessary to drill confirmation wells carefully. Because, there is a good case of reference; Dai Hung field which shrank its reserves by drilling of confirmation wells. However, in the case of "Buried Hill" type of oil field, whether its oil or gas reserves are large or not is difficult to be determined, and the trial and error had been performed during the development work of Bach Ho oil field by Vietsovpetro. Therefore, rashness of determination should be avoided and diligent exploration work should be performed even in the producing stage and we can find oil or gas even in the unexpected area.

It is too early to estimate or determine all the gas reserves in sedimentary basins in Viet Nam at this stage of exploration history. Whether natural gas supply to thermal power plants will be stable or not depends on solely future exploration results of oil and gas. With gas supply from so far discovered 100 billion m³, theoretically it is enough to provide gas to the planned three gas fueled power plants. However, it will not be the situation of confirming these gas reserves in the coming several years.

Next issue of economical point of view is that it will be rather high cost of development of oil or gas fields in off-shore Viet Nam, especially in Nam Con Son basin, where the water depth is deep and the distance from the shore is more than 200 km or nearly 300 km. If discovered oil field is small a marginal, temporary or early production system will be performed, but in the case of large gas field development, the situation is different. There should be a large jacket constructed, or sub-sea completion and production facilities designed, and construction of gas compressor and gas processing facilities with long distance pipeline are prominent. Therefore the development cost of such large gas field in off-shore area is higher than usual case, and unless the circumstance will not be favorable, oil companies can proceed the development stage, otherwise companies will withdraw. BP/Statoil's two gas fields discovery is a typical such case, and they are looking for cooperation development partners of gas and pipeline constructor as their two gas field reserves of 2 TCF are a bit small for their sole development.

Summing up the demand and supply of natural gas to the thermal power generation;

- (1) There are around 100 billion m³ of natural gas reserves so far discovered in off-shore Viet Nam, which is total of all the gas in north, central and south of Viet Nam, while economical and technical development is disregarded. Progress of exploration activity will make discovery of natural gas reserves further more, and its amount will be another 100 billion m³ in future.
- (2) However, actual figure of proved recoverable reserves of natural gas in off-shore Viet Nam is not so large at present. The associated gas of Bach Ho field of Vietsovpetro is confirmed as 20 billion m³, and Rong field gas is 5 billion m³. Other gas reserves, especially BP / Statoil group's two gas fields discovery in Nam Con Son basin; Lan Tay and Lan Do, are not yet proved nor confirmed. Reserves of oil and gas of Bach Ho and Rong had been approved by the state Mine Reserve Committee of Viet Nam while gas reserves of Lan Tay and Lan Do are under the evaluation by the committee at present, and only declared reserves of 2 TCF (60 billion m³) by the company are reported.
- (3) Other fields discovered in off-shore Viet Nam, Dai Hun of BHP group, Rang Dong of Mitsubishi Oil Co. and other oil or gas showing of exploration wells in PS contracted areas of many foreign oil companies, have not yet confirmed their reserves, except Dai Hun

which had started the early production system's crude oil production, and its associated gas is estimated as 3.2 billion m³.

- (4) The associated gas of Bach Ho field will be sent to the shore and will be used as fuels of thermal power plants (Ba Ria, Thu Duk, and Phu My) simultaneously, totally 1.2 billion m³ per year. While, Bach Ho field will have its production peak in 1995, and then it declines in oil and gas production. One of the replacement gas supplying fields for this decline is Rong field near Bach Ho. However Rong is not enough to replace all the declining, and there should be other fields developed and connected with a pipeline to Bach Ho. The most prominent one of them is the discovery of Mitsubishi Oil Co; Rang Dong, while it has not yet confirmed its reserves of oil or gas.
- (5) Development cost of Lan Tay and Lan Do gas fields of BP / Statoil group is rather high because they are situated long distance from the shore and deep water-depth. Gas reserves of the group's announcement; 2 TCF is not so large amount and will not be enough to establish LNG plant economically and its gas is only for the domestic supply. With creating new gas demand, the group plans to develop the fields and lie a pipeline to shore, together with other foreign oil companies which are operating exploration and discovered gas near by the group's blocks.
- (6) It is essentially needed to explore constantly for oil and gas to secure the proved oil or gas reserves, and for this purpose PVA will proceed the accelerated contract policy of Production Sharing with foreign oil companies, with taking foreign companies risky investment, with giving adequate reward to them.
- (7) Exploration work of natural gas resources in off-shore Viet Nam is under way, and it is too early to determine the future availability of gas at present. We should be in careful stance to decide the available amount of natural gas for the thermal power plant. On the point of reserves, there is a definite view on coal rather than gas in Viet Nam.

CHAPTER 8 POWER DEVELOPMENT PLAN

8.1 Basic Concept

This section examines the basic concept and condition arrangement for the establishment of the long term power development plan (PDP) by taking into account the prospect of the power generation energy resources and energy policy in Viet Nam.

(1) Resources limitation

The characteristics of the primary energy resources for power generation, except nuclear power, are enumerated in the following table;

| Political Items | Large Hydro | Small Hydro | Coal | Natural Gas | Oil |
|-------------------------|-------------|-------------|------|-------------|-----|
| a) Domestic Energy | ○ | ○ | ○ | ○ | X |
| b) Renewable Energy | ○ | ○ | X | X | X |
| c) Environment | △ | ○ | △ | △ | △ |
| d) Foreign Money Saving | ○ | ○ | ○ | ○ | X |

Note ○ : Resources clear the constraint items
 △ : Resources required countermeasures
 X : Resources not conformed to the constraint items

From synthetic evaluation of policy items, hydropower, coal and natural gas can be regarded as energy resources for power generation.

(2) Resources development potential

Development potential of coal, natural gas and hydropower, which are limited energy resources, is shown in the following table.

| Resource Factor | Coal (Anthracite) | Natural Gas | | Hydro |
|---------------------|---------------------------|---------------------------------------|---------------------------------|------------------|
| | | Associated Power Sector | Non-associated gas Power Sector | |
| a) Proven Resources | 557 x 10 ⁶ ton | 28.2 x 10 ⁹ m ³ | Not-Proven | 100 TWh |
| b) Demand | Export, Power, Cement | Power Sector | Power Sector | Power Irrigation |
| c) Develop. Period | Short | Medium | Long | Medium |
| d) Develop. Risk | Small | Small | Large | Small |

The resources development potential is determined with the above four factors mutually related. The development potential of non-associated gas is presently unconfirmed. However, the development potential of natural gas expands due to success in gas field drilling in future and new gas demands are expected (heavy chemical industry, public welfare and commerce).

In this situation, the following two proposals are considered as combinations of energy resources for the electric power sector.

Proposal (1) (Water power + coal + non-associated gas)

Proposal (2) (Water power + coal + associated gas + non-associated gas)

In this power development plan, proposal (1) is hereinafter called "gas small" and proposal (2) "gas large".

8.2 Precondition

8.2.1 Power Demand Forecast

The anticipated annual growth rate of power demand is 9% to 14% and the peak load is for lighting in the evening (18:00hrs to 20:00 hrs.). The daily load factor is from 60% to 70%. These values vary with season and region and the basic characteristics will make no great difference in the future.

This power resources development plan uses the daily load curve by region for every hour of the modified type on the basis of the 1993 values in order to meet the kW and kWh values of power demand as forecasted in Chapter 5. (Refer to the appendix for details.)

Demand forecast values to be used in the power development plan are shown in Table 8.2-1.

8.2.2 Power Development Project Site

(1) Development projects scheduled to start operation before 2000

Power resources development project sites planned or constructed for startup before 2000 are shown in Table 8.2-2.

(2) Development projects to be commissioned after 2001

For hydropower candidate sites, the top 15 projects where the B/C exceeds 1 are selected and used for simulation calculation (Refer to Table 8.2-3).

(3) **Matters for attention in hydropower projects**

(a) **Development potential of three major rivers**

Power Generation Potential of Three Major Rivers in Viet Nam

| Item | Unit | Da (North) | | Se San (Center) | Dong Nai (South) |
|--------------------------|-----------------------|------------|---------------------------|--------------------|---------------------|
| | | Son La (L) | Son La (S) +Huoi Quang | | |
| 1) Annual Output | GWh | 17,396 | 13,788 | 4,331 | 4,163* |
| 2) Investment | (US\$ Mil) | 3,485 | 2,785 | 1,229 | 1,346 |
| 3) Annual Cost | " | 657 | 470 | 180 | 170 |
| 4) Annual Benefit | " | 713 | 468 | 168 | 127 |
| 5) B/C | | 1.08 | 1.00 | 0.94 | 0.75 |
| 6) Unit Cost | (¢/kWh) | 3.78 | 3.41 | 4.07 | 4.68 |
| 7) Affected Pollution | (thousand) in 1990 | 106 | 78 | 6.5 | - |

*Note) except for Don Nai 8

The macro development expenses and generation cost of the hydroelectric power generation project seen by three large rivers in Viet Nam (the Da, Se San and Don Nai). All are economically better than those of the thermal power projects. Of these, the generated electric energy and profitability at the River Da are excellent.

When a new power plant is constructed upstream, an increase or decrease of the electric energy generated by the downstream power plant is considered as a benefit for the new upstream power plant and is added to the generated electric energy.

(b) **Son La hydropower project**

As the Son La hydropower development, which is a very large project of the hydropower project points, exerts great influence on the overall development plan, the Son La development is based on the following two proposals.

- 1) Son La large-scale development (Son La (L)) places emphasis on power generation and flood control.
- 2) Son La small-scale development (Son La (S)) mainly places emphasis on power generation and the multi-staged development of the Da river.

In view of the role of this project as flood control and economical power generation cost, its commissioning will be hastened as much as possible and startup of the first plant is set for 2007 in the basic plan in view of construction process which extends over a long period. The Son La (S) case plans integrated development with the tributary upstream Huoi Quang power plant as one set (Refer to Table 8.2-4).

An approximate construction schedule of the Son La and Huoi Quang hydro projects is shown in Table 8.2-5.
