

Table 8-4 Total Cost for Water Supply Project for Small Urban Areas by Province

Province	Total Township Number	New Production (m ³ /day)	Total Cost (Mil. US\$)
Lusaka	1	960	0.66
Copperbelt	3	6,324	3.66
Central	7	13,084	13.32
North-western	2	3,395	4.11
Western	9	16,878	10.16
Southern	18	25,216	22.09
Luapula	2	8,374	6.61
Northern	9	19,373	16.25
Eastern	7	27,956	14.28
Zambia Total	58	121,560	91.14

- 1) Boreholes are equipped with power pumps.
- 2) Diameter of borehole is 30cm.

The cost for water supply in small urban areas is summarized as follows:

- 1) Difference in the cost for drilling one borehole is small by province on the assumption that every province has a drilling centre in its provincial town. The average cost for drilling is US\$25,400 per one borehole. Price of the power pump is a large factor in the cost.
- 2) Difference in the cost for maintenance is small by province. The average cost for maintenance is US\$15,600 per one borehole.
- 3) The average cost of one borehole including both drilling and maintenance is US\$41,000 per one borehole.
- 4) The total cost for each township is different according to the safe yield of the borehole.

The total cost shown in Figure 8-5 and 8-6 includes source development cost (drilling boreholes cost), treatment cost, distribution cost and engineering services

8.3 Cost of Groundwater Development in Lusaka

Cost of completing one borehole is shown in Table 8-6. The borehole cost estimation includes almost the same assumptions as in the case of water supply for small urban areas, however, the length of borehole changes to 100m.

Northern Lusaka Groundwater Supply Project, comprising 50 wells of 20,000m³/day pumpage, is estimated to cost about 16 million US\$. The total cost includes cost for Lusaka Groundwater Training Centre Project apart from source development cost (drilling boreholes cost), treatment cost, distribution cost, engineering services.

<Grand Total>				27,370,000	44,900

8.4 Cost of Constructing Shallow Well

Cost for construction of shallow well is shown in Table 8-7. The cost estimation includes the assumptions listed below:

- Items of cost and unit price are the same as those of DWA.
- Size of shallow well is assumed as 15m in length and 1.2m in diameter.
- Maintenance cost is not included.

Table 8-7 Cost of Standard Shallow Well

Item	Unit Price	Number	
Casual workers	40,000	4	160,000
Windlass	115,000	1	115,000
Well chain	3,000	1	60,000
River sand	9,000 / ton	8	72,000
Crushed stone	12,000 / ton	6	72,000
Pockets cements	4,500 / pocket	23	103,500
Shovels	18,000	2	36,000
Picks	19,500	2	39,000
Blasting	27,000 / rock	3	81,000
Transport & Supervisor	200,000	1	200,000
Sub Total			154,000
Contingency	10%		95,400
Total			1,049,400

In the Table, the item for blasting means breaking up rock at the bottom of wells using dynamite and blasting is assumed as required 3 times for a standard well. However, the amount of blasting depends on geology of the site. The cost of a shallow well is sometimes dominated by the amount of blasting. On the other hand, the number of days needed for completion of a shallow well is as follows:

Table 8-8 The number of days needed for completion of standard shallow well

Digging up to 15m	5 days
Drilling of holes for 3 times blasting	12 days
Removal of debris from well after blasting	3 days
Lining up to 15m from ground surface	16 days
Installation of collar ring, cover, apron and chain	1 day
Total number of days	37 days

The number of days increases rapidly according to the amount of blasting. If the amount of blasting is 6 times, construction period becomes 52 days. The amount of blasting has more weight on the cost than the period of . The cost of a shallow well is less than one fifth as high as that of a borehole. However, the number of days needed for completion of a shallow well (37 days) is more than 7 times as long as that of a borehole(5days). Rapid groundwater development is impossible using shallow wells.

CHAPTER 9 RECOMMENDATIONS

9.1 Continuation of Groundwater Level Observation

Nation wide groundwater level observation is very useful to assess groundwater development potential as carried out in this master plan. The groundwater development potential obtained in the master plan should be examined and, if necessary, should be revised based on new data obtained from continuous groundwater level observation. It is important to observe groundwater level at the same observation points for a long period. From this point of view, 312 observation wells at 169 points established as observation wells in this master plan are useful for continuing observation. Data of groundwater level fluctuation at these observation points was accumulated for one year. Therefore, to continue the observation and obtain new data at these wells will contribute to formulating new groundwater development and management plan in the near future.

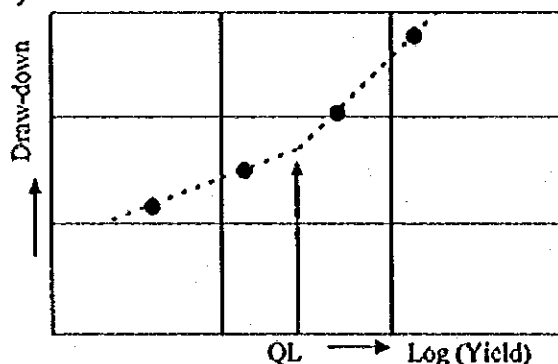

9.2 Continuation of Groundwater Level Monitoring

As explained in the previous section, recently a groundwater table decline in the large cities has been reported. Especially in Lusaka, it is said that the trend of groundwater decline caused by over pumping is remarkable and existing water supply facilities will be damaged in the near future. From this point of view, continuation of groundwater level monitoring is very important. The groundwater levels were continuously monitored from June 1994 to March 1995 by the JICA Study Team. Trends of groundwater level decline were recognized from the records. However, this data is not sufficient to confirm a relationship between the groundwater decline and over pumping. Monitoring over longer periods is needed for that purpose. Effective counter-measures like regulations against over pumping should be examined based on the long term monitoring results. The monitoring stations were constructed by the Study Team and all the monitoring stations were handed over to the responsible organizations. It is desirable for these organizations to continue the groundwater level monitoring.

9.3 Execution of Adequate Pumping Test

9.3.1 Execution of Step Draw-down Test

Step draw-down test is carried out to determine safe yield of a borehole. Step draw-down test is defined as a pumping test to observe draw-downs of borehole with different yields. Safe yield of a borehole is determined as shown in Figure 9-1.

$$\text{Safe Yield} = QL \times (0.7 - 0.8)$$

QL = An intersecting point of two lines as shown in Figure 9-1.

Figure 9-1 Method to Decide Safe Yield

If pumping rate exceeds safe yield, rock fragments enter into the borehole and are deposited on the bottom. If the worst comes to the worst, the wall of borehole and ground surface may collapse. Other than these phenomena, the efficiency of pumping ratio may be reduced in inverse proportion to the pumping rate leading to uneconomical condition. These phenomena mentioned above occur especially in boreholes equipped with power pumps. On the other hand, such the cases occur rarely in boreholes equipped with hand pumps, because yield of hand pump is low. However, proper yields of such boreholes with hand pumps also should be determined in the case of future exchange from hand pump to power pump for rural water supply.

9.3.2 Proper Pumping Test for Aquifer Constants

It is necessary to obtain aquifer hydraulic constants precisely for planning large scale groundwater development. For this purpose, execution of proper pumping test is necessary. As a matter of course, pumping tests are always carried out after completion of boreholes, but those tests are not carried out in an appropriate method in terms of testing the aquifer and obtain the aquifer constants. Important points in execution of a pumping test for that purpose are as follows:

- 1) To drill observation boreholes and to observe groundwater level fluctuation in the observation boreholes during pumping test.
- 2) To keep yield of pumping well constant.
- 3) Before the pumping test, a stepped draw-down test should be carried out to decide the appropriate pumping rate for aquifer constants.

9.4 Effective Use of Borehole Data-Base

The effective use of borehole data-base is desirable for future groundwater development. The advantages of using the data-base are as follows;

- 1) It is easy to retrieve information about aquifers and existing boreholes near new groundwater development sites. From this, the planning of new boreholes, expected yield, length, casing program, etc., are easily carried out according to information derived from the data-base. Borehole data necessary for users are instantly found and printed out. The computer data-base has greatly reduced the time for searching out borehole data.
- 2) Statistical information on aquifers hydrogeology and boreholes capacity by district or province are easily obtained from the data-base. These information is useful not only for actual groundwater development planning but also for scientific hydrogeological study aiming at making clear characteristics of aquifers throughout Zambia.

9.5 Effective Survey for Groundwater Resources

Hydrogeological surveys should be carried out to locate drilling points. The better the survey, the more successful the borehole. Usually, aquifers exist at less than 100m from the surface in Zambia. Therefore, resistivity and electro-magnetic methods are the most useful for survey of such shallow aquifers. On the other hand, these surveys are not always carried out at present due to lack of survey instruments and hydrogeologists, and analysis of the

results is not always sufficient. In addition to the survey mentioned above, regional groundwater potential surveys are needed for large groundwater developments such as the Lusaka groundwater development plan. General survey items for such surveys are, pumping tests and analysis of the results, groundwater level observation, climatic survey and water balance analysis. Based on the results of the survey, a new groundwater development plan should be formulated.

9.6 Standardization of Hand Pump

Types of hand pumps should be standardized in terms of maintenance and repair. Indian Mark II type is the best as the standard hand pump. The reasons are as follows:

- The parts supply situation is better than for other types.
- The cost is lowest.
- The Indian Mark II type is the most widespread use in Zambia.

The government has already decided to standardize hand pump to Indian Mark II type. Therefore, donors should also standardize hand pumps to that type in their support for groundwater development. Boreholes are equipped with several types of hand pumps at present. These hand pumps should be changed to Indian Mark II when they have completed their useful life.

9.7 Construction of Provincial Drilling Center

As part of decentralization, groundwater development is scheduled to be transferred to the jurisdiction of local governments. Accordingly, drilling centers with drilling equipment will be needed in each province. On the other hand, these drilling center do not currently exist except in four provinces. This current situation prevents groundwater development from effective implementation. The borehole drilling plan in this master plan has been made under the assumption that there are drilling centers equipped with drilling rigs with high performance, adequate equipment's and experienced staff in each provincial town. Therefore, the drilling centres will first have to be constructed in order to complete the master plan.

9.8 Establishment of Maintenance and Management System for Rural Water Supply

Existing groundwater supply facilities are frequently not in use for the reason that the maintenance of completed water supply facilities is not adequate especially in rural areas. Therefore, a local maintenance and management system for rural water supply facilities should be established to ensure continuous use of completed water supply facilities. For this purpose, organizing community groups for village water supply is the most useful. Other than that, mobile hand pump repair workers are also useful.

9.9 Training of personnel in charge of groundwater development

Under the Master Plan, about twenty-four thousand boreholes should be completed before 2015. Training of engineers and technicians in charge of the borhole site selection, the machine operation, and the maintenance of equipment is essential to achieve these works. In

addition to the above, training of hand pump repair workers, persons in charge of sanitary education for the local residents and organizers of community groups for rural water supply are also needed. In Zambia, technology transfer related to groundwater development has been carried out by usual grant aid cooperation. In the present situation of this grant aid cooperation, technology transfer is restricted to only a few drilling engineers. Therefore, the establishment of a training centre with excellent trainers and adequate equipment's is needed in order to achieve highly effective technology transfer related to groundwater development and use. The organization and training system of the training centre should be established at an early stage in order to satisfactorily fulfill its function.

CHAPTER 1 INTRODUCTION

1.1 Sector Background

This Part E presents results of the study on water supply sector in Zambia. Chapter 2 describes the present situation of the domestic water sector in Zambia based on past studies, publications, information collected through the study and "Current Water Use Survey" done by the JICA study team during the study period. Water demand projection is presented in Chapter 3. The basic socio-economic study such as projections of population, urbanisation, industrialisation and so on are referred to Part A, "Socio-Economy". On the basis of the present conditions and water demand projection, a master plan of water resources development plan for water supply over the whole country is formulated in Part W of Supporting Report.

1.2 Objective of Water Supply Study

The objectives of the study are: (1) to clarify the present conditions of the water supply sector; (2) to project future potential domestic water demand; and (3) to examine possible countermeasures for development constraints on water supplies in the country. This study does not intend to cover specific water supply schemes.

1.3 Acknowledgment

During the study period, the study team's experts visited various offices for collection of information and received kind help from the officers, to which we wish to express many thanks. In particular, the data through "Current Water Use Survey" were answered by the district water engineers and their staff who know the local conditions. However, as shown in various tables presented in this report, there are still lots of blanks, which were not filled by the district engineers and their colleagues, probably due to lack of basic information. Such information gaps will not affect results of this study, but it is considered necessary to fill out them in the future.

CHAPTER 2 PRESENT SITUATION OF DOMESTIC WATER SUPPLY

2.1 Water Supply Situation

2.1.1 Water Supply Coverage

According to the "Social Sector Rehabilitation and Development Programme, 1993-1996" (Ref.E01), only 43% of the urban population of Zambia has access to safe water and to sanitation structures. In rural areas, only about 30% of the population has access to safe water.

According to the 1990 census, 2.75 million people or 37% of the total population (7.38 million) were served by piped water system in the country, as shown in Table 2-1. Of these served population, 0.97 million people or 35% were served by inside water taps within their houses. 1.37 million or 50% was served by communal taps around their houses. The rest of 0.41 million or 15% was also served by communal taps but their service points were located more than 100 metres away from their houses. In urban areas, 2.46 million people or 85% of the urban population were covered by the piped supply system. In rural areas, however, only 0.29 million people or 6.5% of the rural population were covered by the piped system. 2.32 million or 52% of the rural population was served by well or borehole water sources. Thus, 2.61 million or 58% of the total rural population was covered by the safe water sources in rural areas.

Source: Census of Population, Housing and Agriculture, 1990, Volume 10, CSO (Ref. E02)

From the view point of relation between water demand and water supply capacity which were estimated by the JICA study team, a safe water coverage in rural areas was only 24% in the country. The regional disparity was so large as the coverage in Southern province reached to 67% but that in Northern province was still 8% only. With the exception of Lusaka, Livingstone and Kasama, supply capacities exceed the demands in 12 large urban city. The coverage in small urban areas was still 80%. Even in the large urban areas, the

disparity of the coverage was so large as townships in Copperbelt province were blessed with water resources but those of Lusaka, Livingstone and Kasama were tight as their coverage were 57%, 70% and 67%, respectively. In small townships, those in Copperbelt and North-western provinces were in favourable conditions, but the coverage in Eastern province were only 26%, more serious than that of large urban townships.

2.1.2 Managing Bodies

In principal, most urban water supplies are implemented by local authorities and most rural water supplies are managed by DWA. In addition to it, the actual management of water supply and sanitation systems is divided among various managing bodies as follows because of historical background:

- (a) Central Government: DWA under MESD, MOH, and Department of Community Development under MCDSS
- (b) Local Governments under MLGH: City Councils, Municipal Councils and District Councils
- (c) Parastatals: ZESCO, ZCCM, Zambia Railways, etc.
- (d) Missionaries and Non-Government Organisations (NGOs)
- (e) Private Sectors: Lusaka Water and Sewerage Company Ltd., Chipata Water and Sewerage Company Ltd., Mining Companies, etc.

2.1.3 Target of Water Supply Coverage

In the "Social Sector Rehabilitation and Development Programme" (Ref.E01), the government addresses the water supply goal to fulfill the supply of sustainable safe drinking water to the people. The immediate objective extends the coverage of safe water supplies to 70% of urban people and 35% of rural population by the year 1996. No targets after 1996 have been addressed so far officially.

2.2 Domestic Water Consumers

In urban areas, various supra- and infra-structures as well as residences are settled in accordance with urban agglomeration. These facilities in actual towns are not always composed in conformity with a certain rule systematically, although they should be settled to avert urban and environmental problems and to keep amenity of life. From the point of view of human settlement, Department of Town and Country Planning proposes the Planning Standard for new settlement. This Standard seems to be useful to estimate water demand as a reference for standardisation of water consumers. It was announced for human settlement standard in the "Second National Development Plan, 1972-1976" (Ref. E03). It is summarised in Table 2-2.

Table 2-2 Summary of Planning Standard for Human Settlement

Facility	Standard	Composition	Density:
1. Residential			
a. High Cost Housing	30x45m (1,350 m ²)	2.5%	362.5 persons/ha
b. Medium Cost Housing	18x30m (540 m ²)	15.0%	
c. Low Cost Housing	12x27m (324 m ²)	82.5%	
2. Educational Facility			
a. Nursery School	1 school/4,000 pop. (200 pupils/4,000 pop.)	0.5 ha/4,000 pop.	
b. Primary School	1 stream: 280 pupils/1,500 pop. 4 stream: 1,120 pupils/6,000 pop.	0.8 ha/1,000 pop. 0.5 ha/1,000 pop.	Excludes teachers' housing
c. Secondary School	4/2 stream for 20,000 pop.	5.0 ha/20,000 pop.	
3. Medical Facility			
a. Hospital	District Hosp.: 1/50,000 pop. Provincial Hosp.: 1/100,000 pop. General Hosp.: 1/300,000 pop.		
b. Clinic	600~800 m ² /1,000 pop.	15km radius catchment	
4. Administrative Office			
a. Council Offices	400 m ² /10,000 pop.	Commercial site of 1,500 m ² , including police post, postal agency & local offices	
b. Police Post	400 m ² /10,000 pop.		
c. Police Station	1 ha/30,000 pop.	Plus 2ha residential in residential district	
d. Party Office	400 m ² /4,000 pop.

Source: Planning Standard, MLGH

Yet, this standard seems to be established from an idealistic viewpoint. An actual distribution of infrastructure is somewhat smaller than this standard. For example, a primary school was allotted for every 2,060 population on national average in 1990 and 381 pupils per school in 1992. In the standard, a primary school of one stream has 280 pupils for 1,500 population. The pupil's rate to population is almost the same, but the number of primary school has to be increased more than the actual distribution in order to bring the situation close to the standard. Furthermore, a hospital was allotted for every 950,000 people on national average in 1993. In the standard, however, even general hospital is planned to be established for every 300,000 people. Thus, once the water demand is estimated on the basis of this standard, the estimated figure might be biased to larger side than the actual demand.

Anyhow, it is important to get precise water demand information to establish a water supply system economically. The information of actual distribution of practical water consumers is prerequisite to estimated water demands in the supply areas. Nevertheless, the actual distribution of these facilities is not known even in major townships. In this study, thus, the above planning standard of human settlement is applied instead of the actual distribution of water consumers.

2.3 Water Consumption Rates

2.3.1 Amount of Water Produced and Sold

"Current Water Use Survey" was conducted by the JICA study team in 1994 throughout the country. As a part of the survey, information of water use in urban areas was collected from the 85 schemes, as shown in Table 2-3. The table shows an inventory of water supply projects which are aggregated on the basis of managing body for respective provinces. There are five categories of water supply body in the table.

- (1) DWA: Water supply to small townships or rural villages. These schemes are covered usually by various water sources such as surface water and groundwater. Per capita consumption volume supplied varied in accordance with size of schemes but an overall average was calculated at around 150 lit/capita/day.
- (2) Councils: Urban water supply schemes throughout the country, operated by the local governments under MLGH. Average per capita consumption volume supplied was calculated at around 210 lit/capita/day.
- (3) ZCCM: ZCCM is responsible for water supply covering domestic water and some industrial water for use in production processing in the mine townships. Average per capita consumption volume supplied was calculated at around 450 lit/capita/day. This large per capita volume was probably due to industrial water use combined with increased leakage and wastage.

(4) ZESCO: Small water supply schemes which are located around hydro-electric power plants. Average per capita consumption volume supplied was calculated at around 280 lit/capita/day.

(5) Private Sector: Large water supply schemes, operated by the privatised companies. There are only two cities of which water supply schemes are operated by them, i.e., Lusaka and Chipata. Average per capita consumption volume supplied was calculated at around 210 lit/capita/day, as well.

2.3.2 Unit Rates of Water Consumption

The average unit rates of water consumption are one of the most fundamental information for water demand estimation. In Zambia, the Standardisation Committee was established to provide the standard figures of average water consumption rates in early 80's and to revise them in August 1986. The figures were gazetted in Circulation No.1, "Consumption Figures and Population Projects for Design of Water Supply Systems" (Ref.E04). The major rates were summarised in Table 2-4.

Table 2-4 Summary of Water Consumption Unit Rates

	Facility	Unit	Consumption Rate
1.	Residences		
	- Informal Housing	lit./capita/day	30
	- Low Cost Housing	lit./capita/day	100
	- Medium Cost Housing	lit./capita/day	150
	- High Cost Housing	lit./capita/day	280
2.	Educational Facility		
	- University/College	lit./student/day	120
	- Secondary (non-boarders)	lit./student/day	30
	- Primary (with W/C)	lit./student/day	25
	- Primary (with Pit Latrine)	lit./student/day	15
3.	Medical Facility		
	- Hospital (Urban)	lit./bed/day	365
	- Clinic (without Beds)	lit./patient/day	10

2.4 Public Investment for Water Supply Schemes

2.4.1 Disbursement of Central Government

In relation to the managing bodies, the various public agencies invest public fund to implement water supply schemes. DWA, the authority regarding water supply schemes in the central government, usually disburses its capital expenditure for water projects. Besides, MLGH also invests public capital in water projects not by itself directly but through local authorities. In other words, MLGH loans local governments its capital fund. Table 2-5 shows the summary of public investment for water supply schemes by the central government for the latest six years. In 1994, 27 projects could be implemented directly by the central government. The total amount will reach to K13.7 billion. Eight projects would be implemented by local governments and financed by MLGH. The total amounts would be K19.7 billion. Besides, the local governments would disburse their capital investment (K14 million) for more water projects through their own finance, but their amounts might be very small. It account for only 12% of that (K115.3 million) of the central government.

Table 2-5 Public Investment for Water Supply Schemes by Central Government

Note: "-" means that the agency itself did not exist.

"*" means that the agency has water projects except water supply projects.

2.4.2 Cost Sharing Policy

The cost recovery policy in water resources development and use projects varies in different countries. They range from zero to full cost recovery including the payment of interest cost. In between, partial cost recoveries are widely in practice in accordance with different criteria and socio-political considerations particular to each country.

Water resources development in Zambia will require an accelerated and large amount of investment to keep up with rapid socio-economic development. To meet this requirement, not only effective investment but also efficient recovery of public expenditures should be pursued.

This study envisages two general criteria for formulating the water cost sharing policy.

- (1) The first criterion is a leading criterion that the beneficiaries are required to share, according to the benefits they receive, the entire cost of the public facilities including construction, operation and maintenance costs if the beneficiaries are identifiable and are confined to certain sections of the community. In principal this cost should not be covered by tax revenue collected from general tax payers who include non-beneficiaries, but should be recovered from the beneficiaries themselves as a separate charge. This criterion is based on the free market economy principle and the principle of equity, which encourages the economic efficiency and optimum allocation of national resources.
- (2) The second criterion is that the government grant should be provided only if it is necessary in order (a) to encourage the beneficiaries' participation in development or (b) to provide social amenities from the standpoint of subsidising low income people. Even in this case, the cost recovery policy would rather be discussed with

beneficiaries. For instance, in construction period some beneficiaries might have an opportunity to share some tasks of construction works as task force. In operation and maintenance stage, some O/M works such as simple periodic inspection could be managed by some beneficiaries. By this participation works, the costs for water supply works could be saved in accordance with beneficiaries' attendance.

2.5 Water Tariff

2.5.1 Financial Status of Water Supply Undertakers

According to financial statement of local governments issued by MLGH in 1990, 33 district councils among 55 districts were managing water supply schemes for the people in the districts. Of the 33 district councils, only nine councils got surplus from water undertaking. Other 24 councils managed the water undertaking in deficit. Mufulira council recorded the largest deficit of K2.35 million in 1990.

Water supply services in Lusaka and Chipata townships are managed by private companies, i.e., "Lusaka Water and Sewerage Company Limited (LWSC)" and "Chipata Water and Sewerage Company Limited (CWSC)". They were originally established as municipal undertakers of the respective councils. They were reorganised as private firms under the privatisation policy of the central government.

LWSC is a leading managing company in the country in terms of water supply and sanitation services. It is responsible for water supply and sewage services covering all over the national capital areas. Thus, it is the largest establishment in the field of water supply and sanitation among Zambia.

Table 2-6 shows a balance between revenue and expenditure of LWSC during four years from 1990 to 1993. For the four years, the overall balance of the company recorded surplus in 1990 and 1992, and deficit in 1991 and 1993. Main sources of the revenue were potable water and sewage services which accounted for K3.87 billion or 99% of the total revenue (K3.92 billion including sundry income and investment income). This main revenue consists of two parts: K2.66 billion (68% of the total revenue) of water supply services; and K1.21 billion (31%) of sewage services. The main revenue of consumer services has continuously increased as shown in the table. However, it looks difficult that the company keeps financially sound conditions without reviewing and revising as necessary because of unsteady economic conditions.

**Table 2-6 Profit and Loss Account of Lusaka Water and Sewerage Company:
1990-1993**

Source: Financial Statements, December 1993, Lusaka Water Sewerage Company Limited (Ref.E11)
 Financial Statements, December 1992, Lusaka Water Sewerage Company Limited (Ref.E12)
 Financial Statements, December 1991, Lusaka Water Sewerage Company Limited (Ref.E13)

Assets of LWSC consists of (a) current assets, which include not only general assets such as cash and savings but also account receivable which may include uncollected charges; (b) fixed assets, which include water supply and sewerage facilities and equipment for operation and maintenance; and (c) deferred assets, which include research and studies. The total amount of the assets was reported as K5.25 billion in 1993, as shown in Table 2-7.

The assets of water supply and sewerage facilities owned by the company was evaluated at K2.39 billion in 1993. They comprised (a) K0.21 billion of piping networks for water supply and sewage; (b) K0.54 billion of plant facilities and equipment; (c) K0.09 billion of land and buildings; and (d) K1.54 billion of works in progress. These fixed assets were supported mainly by fixed liability.

The net profits of LWSC during the recent four years were unstable, as seen before. As shown in Table 2-8, a profit ratio of total capital also looks unstable, but the ratio in 1992 was 3.4% which was comparatively large as compared with the Japanese average ratios (1.3% and 1.5%).

A turnover ratio of net worth has rapidly increased, as seen in the table. It was good performance for profitability, but a problem was that the net worth itself shrank and that fixed liabilities rapidly increased. This was not good circumstance for management. A ratio of interest to liabilities were still 4% in 1993, so an interest burden seemed not so heavy for the company. In the future, however, this condition would rather be improved by means of increasing capital and reserves instead of increasing long-term liabilities.

A turnover ratio of fixed assets was higher than that of the Japanese average. This is because the fixed assets was comparatively small. In fact, a component ratio of fixed assets to total assets was 43% in 1992 and 46% in 1993. On the other hand, a rate of depreciation to depreciable fixed assets was large, i.e., 7.3% in 1992 and 9.5% in 1993. It is considered that the depreciable assets were written off at comparatively high rates. This reflected a maintenance level of the equipment and facilities of the plants. It can recover a capital investment within a short period, but it pushes up operating expenses. As a result, it might force to push up a water tariff to meet these increased operating expenses.

A ratio of fixed assets to net worth was 1,189% in 1993 and much worse than those of Japanese entities. On the other hand, a ratio of fixed assets to long-term capital was 60% in 1993 which was not worse. This was because LWSC relied not on its own net worth but on long-term liabilities. Thus, again, this should be improved by means of increasing capital and reserves instead of increasing long-term liabilities.

It is generally said to be desirable that current ratio should be more than 200%. That of LWSC, however, was 155% in 1992 and 91% in 1993. This means that LWSC would be difficult to get short-term loans through creditors.

The company has kept a high level of an operating ratio (around 200%) but has not been able to improve a ratio of current revenue to current expense (around 100%). This was caused by large administrative expenses as seen in Table 2-6. In 1993, the expenses amounted at K2.37 billion, which was 34% larger than the operating expenses of K1.77 billion. It was considered that the expenses included bad debts which was estimated at K1.71 billion in the same year.

Finally, the following recommendations are presented for LWSC, from the point of view of management.

- 1) Net worth is too small and excessively relies on long-term liabilities for capital investment. At present, an interest burden seems to be relatively low but this condition causes cash flow difficulty in the future when the repayment of loan will begin. Thus, LWSC would rather increase net worth as much as possible, which comprises own capital, internal reserves and contribution in aid of construction from beneficiaries. In addition to that, the company should try to find favourable terms of loans for supplemental funds of construction works.
- 2) In 1993, the company spent the large amount of K2.37 billion for administrative expenses. This lies heavy on the management. The heaviest component was bad debt losses. Thus, the company has to exert all possible efforts to charge water tariff correctly and to recover uncollected charges.
- 3) The improvement of operation and maintenance is a key issue to keep the plant machinery and piping network in good condition. This would extend their economic lives and decrease not only O/M costs but also depreciation of the facilities hopefully. It could make water tariff keeping low and steady. As a result, this management policy would get people's dependence on the water supply system and finally recover their reliance on the company.

2.5.2 Present Water Tariff

LWSC presents a tariff of public water services for consumers within the servicing territory of the company. The tariff was revised in October 1994 and again in January 1995. However, 1995's revised tariff was not approved completely by the authority. The present tariff is given in Table 2-9. LWSC will apply the proposed tariff to beneficiaries soon. Figures 2-1 and 2-2 illustrate unit rate of potable water for both the previous tariff in 1994 and the proposed tariff in 1995.

Table 2-9 Water Tariff of Lusaka Water and Sewerage Company Limited

Item	Effective from October 1994 (Kwacha/month)	Revised in January 1995 (Kwacha/month)
Tariff 1 Commercial and Industrial Consumers		
Standing Charge	-	5,000.00
Metered Charge		
0 - 100,000 Litres per 1,000 Litres	198.00	238.00
100,001 - 170,000 Litres per 1,000 Litres	308.00	370.00

Source: Tariffs of Lusaka Water and Sewerage Company Limited

Figure 2-1 Lusaka Water Tariff Effective from October 1994

Figure 2-2 Lusaka Water Tariff Revised in January 1995

2.5.3 Household Expenditure for Water

According to the present tariff of LWSC, typical users of the services are charged the following amount per month.

Table 2-10 Household Expenditure for Water under Tariff of LWSC
(Unit: Kwachas/Household)

Water Consumption Volume (m ³ /month)	Tariff in 1994		Tariff in 1995		Incremental Charge (%)
	Unit Rate Kwacha/m ³	Charge Kwacha /month	Unit Rate Kwacha/m ³	Charge Kwacha /month	
10	88	880	306	3,060	248
20	88	1,760	206	4,120	134
30	106	3,190	195	5,840	83
40	116	4,620	189	7,560	64
50	121	6,020	199	9,940	64
60	125	7,480	205	12,320	65

As shown in Table 2-10, the new tariff became heavy for small water consumers because of standing charge (K2,000/month). A small water consumer of 10 m³/month has to pay a monthly water charge of almost 3.5 times of the previous amount. For water users consuming more than 40 m³/month, however, a charge under the new tariff is around 65% higher than that under the old one.

CHAPTER 3 PROJECTION OF DOMESTIC WATER DEMAND

3.1 Water Supply Target

In this current study, the goal is set to fulfill the safe water supply to urban and rural people as follows: (1) for urban areas, to keep complete coverage in 92 large and small towns and (2) for rural areas, to cover 55% by the year 2005 and 75% in 2015, as discussed in the third steering committee. Thus, the final vision of water resources development schemes will be presented in accordance with this target in the master plan. In action plan, some practical schemes are presented in consideration of various constraints such as environment and financial situation of the county.

3.2 Projection Procedure

3.2.1 Standards and Criteria

The gazette of Circulation No.1 "Consumption Figures and Population Projections for Design of Water Supply Systems" (Ref.E04) stipulates standards and criteria for water demand projection. In this current master plan, the figures of water consumption unit rates in the gazette are applied to estimate water demand as basic information.

The domestic water demand consists of residential and non-residential water demand. The non-residential demand is further broken down to educational, medical, administrative and commercial water demand. It is assumed that these demands are all linearly related to the population concerned. As discussed in Section 2.2, the planning standard for human settlement in Table 2-2 is applied to estimate an inventory of the non-residential facilities. Needless to say, water demand of residential water use is estimated on the basis of future population projected in Part A of Supporting Report.

3.2.2 Water Demand Estimation

Residential water demand is calculated by the following equation.

$$D_{kt} = P_{kt} \sum_i \sum_j C_{ij} H_j UD_{ijt} / 1000$$

Where, k	: target year	1 = 1995
		2 = 2005
		3 = 2015
t	: demand area	1 = urban
		2 = rural
i	: tap connection	1 = individual connection users
		2 = non-individual connection users
j	: housing classification	1 = high cost housing
		2 = medium cost housing
		3 = low cost housing
D_{kt}	: projected demand in year k for demand area t (m^3/day)	
P_{kt}	: number of population	
C_{ij}	: connection rate	
H_j	: housing class rate	
UD_{ijt}	: unit water consumption rate (lit/capita/day)	

The non-residential water demand is calculated by the following equation.

$$I_{kt} = P_{kt} \sum_m N_m UD_m / 1000$$

- where, k : target year
 t : demand area
 m : institutional user type
 I_{kt} : projected non-residential demand in year k for demand area t (m^3/day)
 N_m : ratio of user to population
 UD_m : unit water consumption rate (lit/capita/day)
- 1 = 1995
 2 = 2005
 3 = 2015
 1 = urban
 2 = rural
 1 = education facility
 2 = medical facility
 3 = administrative office
 4 = commercial facility

3.3 Water Consumption Rates

3.3.1 Urban Compound Consumption Rates

Applying "water consumption rates" and "planning standard for human settlement" mentioned in Section 3.2.1, the compound consumption rate in urban area was calculated in Table 3-1. The rate in urban area was classified into (1) large urban area having a population of more than 50,000 and (2) small urban area having a population between 1,000 and 50,000, separately. The compound unit rates of large and small urban areas were estimated at 178.6 lit/capita/day and 142.8 lit/capita/day, respectively. Accordingly, for estimation of water demand, the following compound rates were applied: 180 lit/capita/day for large urban areas and 150 lit/capita/day for small urban area.

Table 3-1 Average Water Consumption Rate in Standardised Urban Area

Facility	Planning Standard	Planned Number		Water Consumption		
		Unit	No.	Unit	Rate	Volume (m ³)
I. Small Urban Area (5,000 Population)						
1 Residence *1						
a. High cost housing	2.5%	house	24	lit/capita/day	280	35.0
b. Medium cost housing	15.0%	house	144	lit/capita/day	150	112.5

(2) Planning Standard, MLGH

Remark: *1 The number of household members was assumed at 5.2 persons on average.

*2 Assumed that people consult a doctor twice a year. (= 2*1,000/200days)

*3 Land area is assumed to need two times of the total floor areas.

3.3.2 Rural Compound Consumption Rates

In the same manner mentioned in the above section, the compound consumption rate in rural area is calculated in Table 3-2. The compound unit rate was estimated at 34.9 lit/capita/day. Accordingly, the compound rates of 35 lit/capita/day was applied for estimation of water demand. The below Table 3-3 shows the applied unit consumption rates in urban and rural areas.

Table 3-2 Average Water Consumption Rate in Rural Area

Facility	Planning Standard	Planned Number		Water Consumption		
		Unit	Number	Unit	Rate	Volume (m ³)
1. Residence						
a. Served People		person	1,000	lit/capita/day	30	30.0
2. Educational Facility						
a. Primary School	1 stream/1,500 pop. (280 pupils/stream) (with Pit Latrine for Toilet)	stream	1	lit/pupil/day	15	2.8
b. Secondary School	3 streams/20,000 pop. (700 pupils/stream)	stream	-	lit/pupil/day	30	0.0
3. Medical Facility						
a. Clinic	1 clinic/1,000 pop.	clinic	1	lit/patient/day	10	0.1
4. Administrative Office						
a. Community Hall	5 staffs/office	staff	5	lit/staff/day	30	0.2
5. Commercial Area						
a. Retail Market	25 m ² /1,000 pop.	m ²	25	lit/m ² /day	3	0.1
6. Other Facilities	(10% of the total of the above facilities)					1.7
7. Total						34.9
Per Capita Consumption Rate (lit/capita/day)						34.9

Source: (1) Consumption Figures and population projections for Design of Water Supply System, Revised August 1986, DWA (Ref.E04)
(2) Planning Standard, MLGH

Table 3-3 Unit Consumption Rates in Urban/Rural Areas

Category	Unit Consumption Rate
Urban Area	
Large Urban Area	180 lit/capita/day
Small Urban Area	150 lit/capita/day
Rural Area	35 lit/capita/day

The water consumption rate of residential use will increase in proportion to improvement of people's living standard. Besides the household uses, non-residential use will also increase as the economic condition goes up. However, the above consumption rates look large enough to meet future demand as compared to present consumption condition which was appeared in the water consumption survey. The planning standard also seems to have some allowance as compared with the actual distribution. Thus, these rates might be

overestimation for projection of present water demand. In this study, however, that estimate is considered to be allowance for present water demand and to be enough for future water demand.

3.4 Projected Domestic Water Demand

The summary of the projected domestic water demand for the three projections is presented in below Table 3-4 for the years of 1995, 2005 and 2015.

Table 3-4 Summary of Domestic Water Demand

Item	(Unit: 1,000 m ³ /day)		
	1995	2005	2015
Medium Projection			
Urban Area	561	744	961
Rural Area	180	217	255
Total	741	961	1,216
High Projection			
Urban Area	581	855	1,261
Rural Area	178	214	251
Total	759	1,069	1,512
Low Projection			
Urban Area	557	712	876
Rural Area	178	207	228
Total	735	920	1,105

Urban potential water demand is tabulated for respective townships in Appendix 1 for the years 1995, 2005 and 2015. District-wise water demand is enumerated for respective districts classified into urban and rural areas in Appendix 2.

3.5 Financial Constraints of Water Sector Development

3.5.1 Constraints in Financial Aspects

The overall deficit of the central government is still large as mentioned in Part-A of Supporting Report. During the recession period, the central government introduced the expenditure ceilings system and restricts the expenditure for the new projects, unless the projects have extremely high economic efficiency. Although it was not clear how long this investment programme would continue, the ceilings system might be considered to continue for the time being.

The government tried to push its fiscal restraint to improve the fiscal situation and to reduce domestic borrowing. Besides, because of the high debt-service ratio in Zambia, it seems to be sensitive for the GRZ to increase external debt for project implementation. This will put the country in an awkward position to expect more external loans.

Foreign grants are another important financial source for development in Zambia. Since the world economy seems to grow at moderate rate for these years, the international economic situation is not always favourable for increasing more financial grants for Zambia. In this international scene, however, several leading donor countries are expected to remain strong in economic growth and to support the developing countries continuously in the future.

Excluding a few water works, most water supply undertakers can not run their own business on the basis of self-supporting accounts. Although the undertakers are still young and have little experience on management of water business, DWA and MLGH are expected to lead them to support themselves by their own accounting in full cost recovering conditions. In that case, DWA and MLGH could bring about new water projects without any financial difficulty. Moreover, so long as the water business succeeds in management, the undertakers could multiply their supply their supply services to their surrounding areas. This would be desirable for water related undertakings.

3.5.2 Charging Policy for Water Supply

It is apparent that the benefit of public water supply systems is only provided to those who are served by the systems. In principle all cost of water should be collected from that section of population benefited by the systems rather than depending on tax revenue.

Yet, rapid expansion in water supply facilities will have to be undertaken henceforward and will be continued for some time span, during which the self-paying operation may not be practicable in view of increasing burden to water undertakers for repayment of heavy loans and interests. In such a case, it may be necessary to consider providing a grant to partly finance the public water supply projects. However, this should be regarded as an intermediate measure to be abolished over the long term.

With regard to rural water supply schemes, the central government's loans with low interest rates would have to be continued for the time being in view of low level income in the rural areas. The government loans should be distributed on an equitable basis for the whole country area in terms of served population ratio and/or health improvement aspects.

Effort should be made to encourage sound financial management in public water supply projects. Water tariff should be reviewed regularly and revised as necessary. Until the time when self-paying operation is established at each water supply system, it is desirable to apply a common water tariff, probably each for urban and rural schemes, throughout each district with the exceptions of such areas that specifically higher rates should be applied for control of the overall quantity of water consumption, such as Lusaka requiring extensive water transfer.

One of the objectives of public water supply is to provide essential amenities for general social well-being. Water tariff should be so designed to impose a low water charge rate for the minimum consumption to meet basic needs. To encourage water saving, on the other hand, a progressive water charge rate should be introduced.

In case of self-help schemes, settlement schemes, and some of rural water supply schemes which aim to meet the basic needs, the beneficiaries may be required only to meet the cost of operation and maintenance of the project.

3.5.3 Prioritisation of Implementation Schemes

It is a fact that the water supply sector has a major constraint in its implementation, that is the limited budgetary resources. However, a great demand is raised from people for early supply of water. This tends in some cases to embark on the implementation of schemes

more than the budgetary capacity. Although this is quite hard to the responsible implementors, a practical approach is to reduce the number of implementation schemes within the constraint of budgetary resources actually available, so that the scheme could be completed at an economical implementation speed.

CHAPTER 1 MANUFACTURING SECTOR SITUATION

1.1 Past Development Trend

Industrial production index over the past 10 years since 1980 is shown in Table 1-1. The table shows that all industrial production (total index) decreased slightly from the level of 1980. The present activity (1992) of the mining sector stands at almost 20% less than that in 1980; in particular, coal production decreased by almost 25%. In spite of this, the manufacturing sector increased by almost 34% from 1980. Within manufacturing, "Food & Beverages" increased sharply by almost 70%, "Chemicals, Rubber & Plastics" also increased by 40% and "Textiles and Clothing" increased by 27% which is almost the same as the rate of increase of the total manufacturing sector. On the contrary, "Basic metal industries" stand at almost 60% of the 1980 level and "Metal products" have remained at almost the same level since 1980.

Table 1-1 Index of Industrial Production (1980=100)

Year	Weight	1980	1981	1982	1983	1984	1985	1986	1987	1988	1989	1990	1991	1992 (**)

1.2 Manufacturing Characteristics

In order to understand the Zambian manufacturing sector, Table 1-2 shows Value Added by industry type in 1990 and a comparison of the number of establishments and employees by industry type in 1980 and 1990.

Table 1-2 Manufacturing Establishments and Employees by Industry Type

Notes:

- 1) Data in 1976 and 1980 are based on "Census of Industrial Production, 1974 and 1980".
- 2) Data in 1990 are based on information given by CSO.

The table shows that, from the viewpoint of Value Added, number of establishments and number of employees, "Food & Beverages" is the leading sector accounting for almost 40% share of total manufacturing sector. "Textiles & Leather" accounts for almost 22% of total employees, and almost 7% of total Value Added, whereas "Metals & Machinery" accounts for almost 30% of total Value Added. This implies that Value Added type of industry should be expanded to achieve national economic development. However, as stated above, the "Metal & Machinery" sector has not been developed over the past 10 years. "Food & Beverages" and "Textiles & Leather" make a large contribution to the national economy by not only creation of employment opportunities but also by supplying to the domestic demands. For these reasons, such industries have expanded noticeably in the past.

1.3 Regional Industrial Characteristics

Regional industrial distribution is illustrated in Table 1-3 by the number of establishments and employees, based on CSO information. The industrial census was made in 1990; however, results and analysis have not yet been published.

Table 1-3 Regional Industrial Accumulation in 1990

- No. of Employees	29,877	15,195	3,584	3,368	8,012	2,606	926	6,516	273	70,560

Note: Prepared on the basis of industrial data in 1990 as given by CSO.

The table shows that almost 40% of the total number of establishments and total employees are located in Lusaka Province and another 42% of total number of establishments and 34% of total employees are located in Copperbelt Province. Of lesser importance are Southern Province, with almost 10% of total establishments and employees, and Central Province with almost 5% of industries.

Generally, Lusaka is the most industrialised province; however, Copperbelt Province is more advanced in "Metal & Machinery" industries than Lusaka. Although most industries are located in Lusaka and Copperbelt Provinces, "Food & Beverages", "Textiles" and "Wood & Furniture" are distributed nation-wide. In other words, light industries exist in all provinces, while more technically advanced industries such as metal and machinery industries are mainly concentrated in Lusaka and Copperbelt Provinces.

1.4 Export and Import Structures

Current trade balance is shown in Table 1-4. Zambia's trade balance is different from other African countries in that many countries have trade balance deficits. However, with the exception of recent years (1992-1994), Zambia earns foreign exchange from the export of copper and cobalt, as well as smaller amounts of lead, zinc and precious metals. Non-ferrous metals account for almost all of Zambia's foreign exchange earnings as shown in Table 1-5.

Table 1-4 Trade Balance of Zambia

Items	1987	1988	1989	1990	1991*	1992*	1993**	1994**

(Trade Balance)	96	267	387	179	133	-72	-70	-95

Notes: * Estimates ** Projections (%) shows share of total exports or imports

Source: New Economic Recovery Programme, March 1992

However this export share has decreased slightly because the unit price of copper and other metals has decreased. Instead, the export of non-metallic products has increased. Additionally, the export of electric energy has increased. Machinery and petroleum account for a large share of imports which is similar to the situation in other African countries.

In addition to industrial products, petroleum products and petroleum account for almost 15% of total imports, ranking first in import items. Specialised machinery for particular industries is ranked second, followed by general industrial machinery, chemicals, cereals and cereal preparations, etc.

Table 1-5 Value of Imports and Exports of Selected Commodities

(Unit:K'million)

Notes: 1) Selected commodities are relatively large amount of imports

2) Average share is calculated as each commodity value in 1991 and 1992 divided by grand total in both years

Source: External Trade Bulletin 1993, CSO

1.5 Manufacturing Activities

Large scale industrial operations in Zambia are undertaken by the state conglomerate, the Industrial Development Corporation Ltd. (INDECO) under the Zambia Industrial Mining Corporation Ltd. (ZIMCO).

1.5.1 Zambia Industrial Mining Corporation Ltd. (ZIMCO)

ZIMCO was established in 1969 to act as the holding company for the emerging state-controlled mining companies. ZIMCO's shares are owned by the State through the Minister of Finance, but are not directly owned by the government. There are reports that ZIMCO controls 80 per cent of the national economy. The ZIMCO group is composed of state-controlled enterprises (with at least a 51 per cent share held by the Zambian government) throughout all economic sectors, and is responsible for the discovery, management, and production of the country's mineral resources. However, in August 1992, ZIMCO's Board adopted a resolution that restructured the corporation into a smaller investment holding company with the disbanding of INDECO and NHDC.

1.5.2 Industrial Development Corporation Ltd. (INDECO)

Until as recently as 1992, the Industrial Development Corporation Ltd., (INDECO) participated directly in business operations and was the government's vehicle for implementing economic reforms because the organisation had acquired the majority shareholdings in designated companies. However, as a result of the Parliament's 1992 approval of the Privatisation Act, and the country's Structural Adjustment Programme (SAP), new economic policies affecting INDECO's business holdings were inaugurated. The policies specifically established the sale of parastatal companies.

Recent economic liberalisation programmes curtailed INDECO's ownership in the production sectors and was designed to promote privatisation of the economy as listed below :

- New investment incentives (June 1992)
- Zambia Investment Centre (June 1992)
- Privatisation Act (July 1992)

CHAPTER 2 MINING SECTOR SITUATION

2.1 Summary Description

Public investments for ZCCM projects are designed to attract funds from international financial institutions such as the African Development Bank and the World Bank. Emphasis is placed on the mining sector because the Government estimates that the copper industry will remain the main economic force in the country for the medium term as a major source of foreign exchange. The government is moving forward with plans to privatise ZCCM. Stanford Research Institute has a contract under a World Bank mining sector loan to carry out a strategic survey of ZCCM, including an examination of the best course to follow in privatising ZCCM.

Also, the Government recognises that there is substantial mineral wealth to be exploited which includes metals, gemstones, industrial, agro, building, and energy minerals. Currently, the most developed sector is the metallic group.

Currently, mined deposits are expected to be exhausted by the end of the century, but there are undeveloped reserves. The Ministry of Mines is actively seeking foreign partners to develop these reserves. In 1992, Phelps Dodge Inc., received prospecting licenses for the Lumwana deposits in the Northwestern Province, and has commenced exploratory work. Priority projects under the investment programme are:

- Acid plant rehabilitation
- Deepening of the Mindola Shaft, and the
- Reopening of Konkola No. 3 Shaft.

2.2 Zambia Consolidated Copper Mines (ZCCM)

In 1982, the mining companies, Nchanga Consolidated Mines Ltd., (NCCM) and Roan Consolidated Mines Ltd. (RCM), were amalgamated as Zambia Consolidated Copper Mines (ZCCM). Of ZCCM's outstanding shares, ZIMCO has about 60.3% equity shareholding.

A summary of the ore reserves and mineral resources of the 11 primary mining operations is given in Table 2-1, and a summary with detailed descriptions of ZCCM's business operations, e.g., divisions, production, ore deposits/reserves, plant capacities, etc., is presented in Table 2-2.

Table 2-1 Ore Reserves and Mineral Resources by Mining Location

Mine Nomenclature	Ore Reserves*	Mineral Resources**
Nchanga	82.582 Million tonnes	388 Million tonnes
Mufulira	43.173 Million tonnes	381 Million tonnes
Nkana	87.569 Million tonnes	144 Million tonnes
Chibuluma	4.060 Million tonnes	11 Million tonnes
Luanshya	29.375 Million tonnes	44 Million tonnes
Baluba	40.310 Million tonnes	28 Million tonnes
Nampundwe	8.073 Million tonnes	18 Million tonnes
Kabwe	1.063 Million tonnes	56 Million tonnes
Chambishi	--	136 Million tonnes
Kansanshi	--	26 Million tonnes

Notes:

- * indicates "ore reserves" that are defined as that tonnage which meet the definition of ore and are available for mining from existing or approved planned facilities.
- ** indicates "mineral resources" that are defined as those mineralised materials which have been examined in sufficient detail to establish mode of occurrence, size, and essential qualities, and include reclamation materials already mined or treated. Before transfer to the "ore reserve" category, investigation into the feasibility of economic exploitation must be accomplished and additional investment incurred.

CHAPTER 3 INDUSTRIAL WATER SUPPLY

3.1 Manufacturing Sector

To understand the unit water consumption rate by industry type in Zambia, the Study Team conducted a questionnaire survey supported by DWA and ZACCI (Zambia Association of Chambers of Commerce and Industry) between February and April 1994. The Team dispatched questionnaires by mail to about 1000 enterprises. The number of questionnaires returned by manufacturers was 139 samples which accounts for about 20% of manufacturers listed in the 1990 statistical data of CSO. A projection of future water consumption was conducted based on the analysis of the replies received. The water consumption rate by industry is estimated as shown in Table 3-1.

Table 3-1 Estimate of Water Consumption Rate by Industry

ISIC Code	Type of Industry	(a) No. of Est.	(b) No. of Employees	(c) (b)/(a)	(d) No. of Sample	(e) No. of Employees	(f) Cons. Rate (m ³ /d/Est.)	(g) Cons. Rate (m ³ /d/1000m ²)	(h) Cons. Rate (m ³ /d/Est.)

[Note] 1) (a) and (b): Industrial statistical data (1990) are given by CSO. 2) (d) ~ (h): Results of questionnaire survey. 3) (a): Total number of industrial establishments in Zambia (1990) (b): Total number of employees in industrial sector (1990) (c): Average number of employees per establishment (1990) (d): Total number of samples obtained in questionnaire survey (e): Average number of employees obtained in questionnaire survey (f): Average water consumption rate (m³/day/establishment) (g): Average water consumption rate (m³/day/1000m²) (h): Weighted average water consumption rate (m³/day/establishment)

3.2 Mining Sector

Large scale mining operations in Zambia are undertaken by ZCCM as explained previously. To understand the water consumption for mining sector (processing plant), the Team visited ZCCM operational sites located in Copperbelt Province and contacted ZCCM head office. The following figures were disclosed by ZCCM.

- Chililabombwe	: 8,000 m ³ /day	- Konkola	: 50,000 m ³ /day
- Nchanga	: 78,800 m ³ /day	- Mufulira	: 53,000 m ³ /day
- Nkana	: 25,400 m ³ /day	- Chambeshi	: 23,400 m ³ /day
- Luanshya	: 52,000 m ³ /day	- Baluba	: 15,900 m ³ /day
- Kabwe	: 13,700 m ³ /day		

According to ZCCM current plans, the estimated end of life of Luanshya mine is year 2005 and Baluba mine is year 2012. An estimate of the Division's total industrial water usage during the years 2005 to 2012 is 32,000 m³/day. In addition to ZCCM's activities, coal production has been undertaken by Maamba Collieries Ltd.(MCL) at Maamba in Southern Province. According to the questionnaire answered by MCL, water consumption for coal production (coal processing plant: capacity 450,000 tons per year, capacity utilisation 38 %) is 2,800 m³/day.

CHAPTER 4 INDUSTRIAL WATER DEMAND FORECAST

Industrial water demand for manufacturing sector is assumed at city and district level over the whole country by the following study steps.

- 1) Industrial development forecast is made on the basis of production amount (VA: Value Added) by industrial type which is projected by macro-economic development as described in Supporting Report [A].
- 2) Industrial development forecast by district level is also assumed by the present industrial situation such as the existing industrial accumulation and regional population growth.
- 3) Unit water consumption rates by industrial type are estimated on the basis of analysis of results of questionnaires answered by manufacturing enterprises in Zambia.
- 4) Industrial water demand in 2005 and 2015 are assumed by growth of industrial type by district and unit water consumption rate.

4.1 Industrial Development Forecast

As discussed in Supporting Report [A], the GDP projection of manufacturing sector in the year 2015 according to Base Case(1) is given as K 766.2 billion. Value added forecast of the manufacturing sector is broken down by the above manufacturing growth rate and past growth rate of each industrial type. According to this analysis, average industrial sub-sector growth rates are obtained as shown in Table 4-1.

Table 4-1 Industrial Sub-sector Growth Rate

Industrial Sub-sector	Share in 1993	1993-2005	2005-2015
Food, Beverages, etc.	41.5%	4.0%	4.0%
Textiles & Leather	5.5%	2.9%	2.8%
Wood & Furniture	2.1%	3.2%	3.1%
Paper & Printing	2.9%	3.2%	3.2%
Chemicals	18.2%	3.6%	3.6%
Non-Metallic Products	11.5%	4.1%	4.0%
Iron & Steel	0.3%	2.4%	2.3%
Metal & Machinery	5.9%	3.5%	3.4%
Other Manufacturing	2.0%	4.8%	4.7%
(Average)	100%	3.6%	3.6%

Note: Growth rate is calculated from Base Case(1) of GDP Projection

Growth rates of "Food/Beverages" and "Non-Metallic Products" are slightly higher than the average rate and other sub-sectors are below the average rate. "Food/Beverages" accounted for about 42% in 1993 and was the largest sub-sector in manufacturing sector. It can be said that the industrial development situation in Zambia is only at the early stages of industrialisation.

According to data of external trade, imports of food/beverages and non-metallic products are relatively high. To reduce foreign exchange, these industries should be developed within Zambia in the future. Value added forecast by industry in 2005 and 2015 based on the above rates is shown in Table 4-2.

Table 4-2 Industrial Structure Forecast in Zambia

Value Added in Basic Value (K'Million)

38	Total Metals & Machinery	48	96	10,347	55,887	84,041	117,339
39	Total Other Manufacturing	1	2	1,089	6,948	12,159	19,219
3	TOTAL MANUFACTURING	224	457	36,107	350,503	538,900	766,200

Notes: 1) Figures for 1974, 1980 and 1993 are current prices based on the Industrial Census.

2) Figures for 2005 and 2015 are constant prices at 1993 levels as estimated by the Team.

Manufacturing sector will increase by almost 220% in 2015 from the present level. Thus, this sector is a significantly important sector for Zambia. From this sector, "Food/Beverages" accounts for 42% of total manufacturing.

4.2 Regional Industrial Development

According to industrial statistics in 1990 given by CSO, there are 665 manufacturing enterprises with a total of 70,357 employees in the whole country. Industrial water consumption depends on industrialisation at both national and regional level. It is advantageous to estimate industrial water consumption at the regional and district level; therefore, the present industrial situation and future development frame should be drafted at the district level. The results of the present industrial accumulation and annual growth rate by Province and township are shown in Table 4-3.

Table 4-3 Manufacturing Distribution Ratio by District in 1990

Notes:

1) Distribution ratio is based on number of employees by type of industry and by township.

2) Ratio is calculated by the Team.

Source; Number of employees in 1990 is given by CSO.

Manufacturers are mainly located in Lusaka and Copperbelt Provinces which account for 75% of all manufacturing industry. In particular, Lusaka city is the most industrialised region in Zambia accounting for about 40% of total manufacturing industry. Secondly, Ndola city in Copperbelt accounts for about 10% of total manufacturing industry. Although the manufacturing share of Copperbelt is lower than Lusaka province, its share of "metal & machinery" and "chemicals" is larger than Lusaka province. This implies that Copperbelt is a more industrialised region than Lusaka Province. On the other hand, the least industrially developed province is North Western Province which accounts for only 0.3%.

Future regional industrial development is assumed based on the growth rates of industrial sub-sectors and district population combined with the present industrial accumulation by districts. The reason why population growth rate is employed for the assumption of industrial development is based on the fact that employment opportunities should be expanded to match increasing population growth rate.

4.3 Unit Water Consumption Rate

Unit water consumption rates vary widely from industry to industry and from country to country. To grasp unit water consumption rate by industrial type in Zambia, the Study Team conducted a questionnaire survey supported by DWA and ZACCI (Zambia Association of Chambers of Commerce and Industry) between February and April 1994. The number of

questionnaires answered by manufacturers was 139 samples which accounts for about 20% of manufacturers listed in the 1990 statistical data of CSO.

The assumed unit water consumption rates are categorised by sub-sector, as given by the two digit ISIC codes (International Standard Industrial Classification). In order to avoid discrepancies caused by differences in scale between those establishments who responded to the questionnaire survey and the national average in Zambia, the following weighting formula is employed for analysis of unit water consumption rate. The analytical results are shown in Table 4-4.

$$U_r = \sum_i \{AWC \times NAN / ANE\} / NME$$

Where,

- Ur: Unit water consumption rate by sub-sector (2 digit ISIC code)
- AWC: Average water consumption per sample (3 digit ISIC code)
- NAN: National average number of employees (3 digit ISIC code)
- ANE: Average number of employees per sample (3 digit ISIC code)
- i: Number of manufacturing establishments by industrial type (3 digit ISIC code)
- NME: Number of manufacturing establishments by sub-sector (2 digit ISIC code)

Table 4-4 Average Water Consumption Rate by Industry

ISIC Code	Industrial sub-sector	Number of Manufacturing Establishments	Number of Samples Collected	Collection Rate (%)	Weighted Average Consumption Rate (m ³ /day)
31	Food, Beverage etc.	200	26	13	910.5
32	Textiles & Leather	125	10	8	84.6
33	Wood & Furniture	54	9	17	24.3
34	Paper & Printing	53	6	11	28.1
35	Chemicals	79	29	37	296.3
36	Non-metallic Products	28	12	43	57.1
37	Iron and Steel	17	3	18	10.9
38	Metals & Machinery	105	42	40	15.9
39	Other Manufacturing	4	2	50	5.1
3	Total Manufacturing	665	139	21	159.2

4.4 Industrial Water Demand in 2005 and 2015

4.4.1 Manufacturing Sector

Water demand of the manufacturing sector is estimated by using the following formula. The mining sector is dealt with separately below, because mining sector activity in Zambia is quite significant and solely operated by ZCCM.

$$MWDD = \sum_{i=1}^n (U_i \times NME_i) \times (1 + GR - WR)^r$$

Where,

- MWDD : Manufacturing water demand by district
- n : Number of manufacturing sub-sectors
- U_i : Unit water consumption rate by sub-sector (2 digit ISIC code)
- NME : Number of manufacturing establishments by sub-sector
- GR : Annual growth rate by sub-sector
- WR : Annual growth rate of water recycling
- r : Years up to the targeted year

Generally, the water recycling rate in a country normally increases in parallel with industrial advancement. In this study, water recycling growth rate is set at 0.5% per annum in consideration of Japanese past performance which recorded an increase of 6.5% over 13 years (water recycling rate in Japan increased from 68.8% in 1976 to 75.3% in 1988). From the results of the above analysis, assumed water consumption volumes in 2005 and 2015 are shown in Table 4-5.

In 1990, the water consumption volume of Lusaka province was almost the same as that for Copperbelt province. The two provinces accounted for more than three quarters of total water consumption in the manufacturing sector. From the viewpoint of city or district level, Lusaka city is the highest consumer of industrial water (76,500 m³/day) and accounted for almost one third of total water consumption (222,400 m³/day) in the manufacturing sector in 1990. In second place, Ndola city at about 23,600 m³/day accounted for almost 10% of total industrial water consumption. Other major users in Copperbelt province are Kitwe city and Chingola.

By 2015, the industrial water demand of Lusaka city will have increased by about 230% from the 1990 level, and will account for 40% of total manufacturing water demand. Ndola's manufacturing water demand will also increase; however, the rate of increase is slightly lower than for Lusaka city because of differing rates of industrialisation.

4.4.2 Mining Sector

Water consumption rates in the mining sector vary widely depending on type and capacity of processing plant. There are various mineral processing plant, such as concentrators, smelters, refineries and other mineral plants, located at the different ZCCM Divisions or mines. Therefore the present water consumption rates as given by ZCCM are applied for the mining sector and future water consumption is assumed as almost the same volume, because ZCCM expects to maintain annual copper production at the present level of 440,000 tons in future. It is noted that other potential development ores have been identified; however, water consumption rates are not mentioned because detailed development plans are not known at present. Resulting from the above, assumed water consumption volumes for the mining and manufacturing sectors are shown in Table 4-5 and summarised as follows:

		(1990)		(2005)		(2015)	
Mining	(1000m ³ /day)	307.1	(58%)	307.1	(46%)	307.1	(41%)
Manufacturing	(1000m ³ /day)	222.4	(42%)	366.7	(54%)	446.1	(59%)
Total	(1000m ³ /day)	529.5	(100%)	673.8	(100%)	753.2	(100%)

Water consumption in the manufacturing sector will exceed the mining sector by the years 2005 and 2015. Water consumption in manufacturing sector will increase by almost 165% in 2005 and 200% in 2015 from the 1990 level. Water consumption of Copperbelt province, with most of Zambia's mining industry, accounts for almost 70% of the national total at present; this share will decrease to 67% by 2015. On the other hand, Lusaka Province's share will increase to 25% of the total in 2015 from 16% in 1990.

Notes:

- 1) Figures in mining sector are based on ZCCM's information.
- 2) Chingola contains ZCCM's Nchanga division.
- 3) Kalulushi contains ZCCM's Chibuluma mine.
- 4) Luansha contains ZCCM's Baluba mine.

4.4.3 Case Study

Water consumption stated above is assumed based on Base Growth Case - Agricultural Expansion of projected GDP in the industrial (manufacturing) sector. In addition, the following case study of water consumption for Base Growth Case - Industrialisation and Low Growth Case of GDP projection, is described below. Average annual growth rates are calculated according to GDP projections for both the Industrialisation (maximum) and the Conservative (minimum) assumptions.

Table 4-6 Projected GDP in Max. and Min. Assumption

Projection Case	Projected GDP (K Million)			Ave. Annual Rate of Increase	
	1993	2005	2015	1993-2005	2005-2015
(1) Base Growth Case - Agricultural Expansion (Medium Assumption)	350.5	538.9	766.2	3.6%	3.6%
(2) Base Growth Case - Industrialisation (Maximum Assumption)	350.5	728.6	1,152.8	6.3%	4.7%
(3) Low Growth Case (Minimum Assumption)	350.5	454.8	534.7	2.2%	1.6%

The same formula is employed to estimate industrial water consumption for manufacturing sector. The projection results for the national total and for 3 cities and 9 municipalities are as shown in Table 4-7.

Table 4-7 Industrial Water Demand Forecast in Max. and Min. Cases

(unit: 1000m³/day)

- Kasama	5.1	6.5	10.0	5.6	7.1	10.9
- Chipata	6.3	8.0	12.4	7.3	9.3	14.3
[Above Total]	232.7	293.2	447.3	287.2	361.5	551.7
[National Total]	291.8	366.7	557.5	354.8	446.1	678.4

Comparing GDP projection in 2015, the Base Growth Case - Industrialisation (1,152.8 billion Kwacha) stands at almost 50% higher than the Base Growth Case - Agricultural Expansion (766.2 billion Kwacha) and the Low Growth Case (534.7 billion Kwacha) stands at almost 30% less than the Base Growth Case - Agricultural Expansion. In the case of industrial water consumption, however, the Low Growth Case (minimum assumption) gives a figure almost 20% less than the Base Growth Case - Agricultural Expansion (medium assumption). Base Growth Case - Industrialisation (maximum assumption) shows almost the same differential as GDP of 50% higher than the Base Growth Case - Agricultural Expansion.

CHAPTER 1 INTRODUCTION

This supporting report describes the Current Water Use Survey undertaken as part of the Study on the National Water Resources Master Plan by a local consultant on behalf of the JICA Study Team. The aims and objectives of the survey, the survey methodology and the results and conclusions are described in detail in the following chapters.

The survey has identified the areas of maximum water use in Zambia and has provided data for use in the sections on current and future water balance in the main report. It has assessed the current situation regarding the administration of water rights for the abstraction of surface water from rivers. An understanding of the status and operational problems of the existing water supply projects, based on the replies to a questionnaire survey, has been gained. Overall, the current water use survey has provided valuable information on the level of water consumption in Zambia at the present time and has greatly assisted the prediction of future demands necessary for planning of water resources development.

The valuable assistance of the hard working staff of the Water Development Board, in particular, Mr J. Chilo and Mr A. Mondoka, to both the JICA Study Team and the local consultant is gratefully acknowledged. The efforts of the staff of the local consultant, Rankin Engineering, in the collection of data and the undertaking of the extensive questionnaire surveys are also gratefully acknowledged. Particular thanks to Mr V. Alavian of Rankin Engineering are also due for his valuable advice and professional management of what proved to be an arduous task to collect so much data in such a short time from across the whole of Zambia.

CHAPTER 2 AIMS OF THE CURRENT WATER USE SURVEY

The overall aim of the Current Water Use Survey was to assess the existing situation in the Republic of Zambia with regard to the supply of and demand for water. This information is necessary for the National Water Resources Master Plan to identify areas where there is currently a shortfall in the amount of water supplied, and to predict which areas are likely to experience difficulties in the future.

The current level of water use and the condition of existing water supply facilities was evaluated from several surveys undertaken on behalf of the Study Team by a local consultant. These surveys included the collection of data from the existing Water Rights records, a questionnaire survey of water supply scheme managing bodies and a questionnaire survey of large scale irrigation projects. Collection of socio-economic data related to current water use was also included in the survey. The local consultant was also required to visit water supply and irrigation projects, as well as municipal and district councils and provincial government offices.

CHAPTER 3 OBJECTIVES OF THE SURVEY

There were five main objectives of the Current Water Use Survey undertaken as part of this National Water Resources Master Plan Study. These objectives are outlined briefly below and then the survey methodology for each of the objectives is described in detail in the following chapter.

1. WDB Water Rights Records

The Water Development Board (WDB) has records of approximately 4000 Water Rights granted over the last thirty years for the abstraction of surface water from Zambia's rivers. The objective of the existing water rights survey was to extract relevant information from each of the record files and input this data to a computer database. The database was then analysed to give an estimate of the volume of water currently used for domestic water supply, agricultural water supply (for both irrigation and stock watering), industrial water and hydropower generation.

2. Domestic Water Supply Projects

Domestic water supply projects in Zambia are largely managed by either the DWA or local authorities, such as city, municipal or domestic councils, under the Ministry of Local Government and Housing (MLGH). In addition, there are two semi-autonomous water supply companies serving Lusaka and Chipata, and other water supply projects operated by ZCCM and ZESCO. The objective of this section of the survey was to compile a detailed inventory of all existing water supply projects and to identify the current level of supply and condition of the facilities. Questionnaire forms were distributed by the local consultant to all known managing bodies and the information from the replies received was input to computer database.

3. Irrigation Water Supply

Lists of known large scale irrigation projects and small holder schemes were obtained from the Department of Agriculture of the Ministry of Agriculture, Food and Fisheries. The objective of the irrigation water supply survey was to obtain additional data to be used in the Agriculture and Irrigation sections of the Master Plan Study. Questionnaire survey forms were sent to project managers and the information from the replies received was analysed as part of the Irrigation study.

4. Socio-Economic Survey

The objective of the socio-economic survey was to collect additional information related to current water use. This information included the performance of the regional economy, inventories of social infrastructure and housing for all urban townships, and details of regional and urban development plans. Questionnaire survey forms were sent to the nine provincial Offices of the President.

5. Field Survey Trips

To supplement and verify the information obtained from the various questionnaire surveys outlined above, the local consultant and the Study Team made several field survey trips throughout Zambia. The main objective of these field trips was to overcome the communication difficulties, such as faulty telephone / facsimile lines and unreliable postal services, and to encourage and assist the bodies concerned to provide the information required.

CHAPTER 4 SURVEY METHODOLOGY

4.1 Survey of Existing Water Rights Records

The Ministry of Energy and Water Development (MEWD) is responsible, through the Water Development Board (WDB), for the issue and administration of all Water Rights for the abstraction of surface water from Zambia's rivers. It was originally thought that the WDB held records of approximately 4-5000 Water Rights granted over the last thirty years. However, in the course of the survey, it soon became apparent that the actual number of records was considerably less. The objective of the existing water rights survey was to extract relevant information from each of the record files and input this data to a computer database. The database was then analysed to give an estimate of the volume of water currently used for domestic water supply, agricultural water supply (for both irrigation and stock watering), industrial water and hydropower generation.

The local consultant's staff were based in the Water Development Board (WDB) office for a period of about one month. During that time, all the available Water Rights records that could be located in the Water Board Registry, the various Water Board offices and also the Land Registry office were reviewed and the relevant data abstracted to the survey form. A copy of the survey form is included in the Appendix.

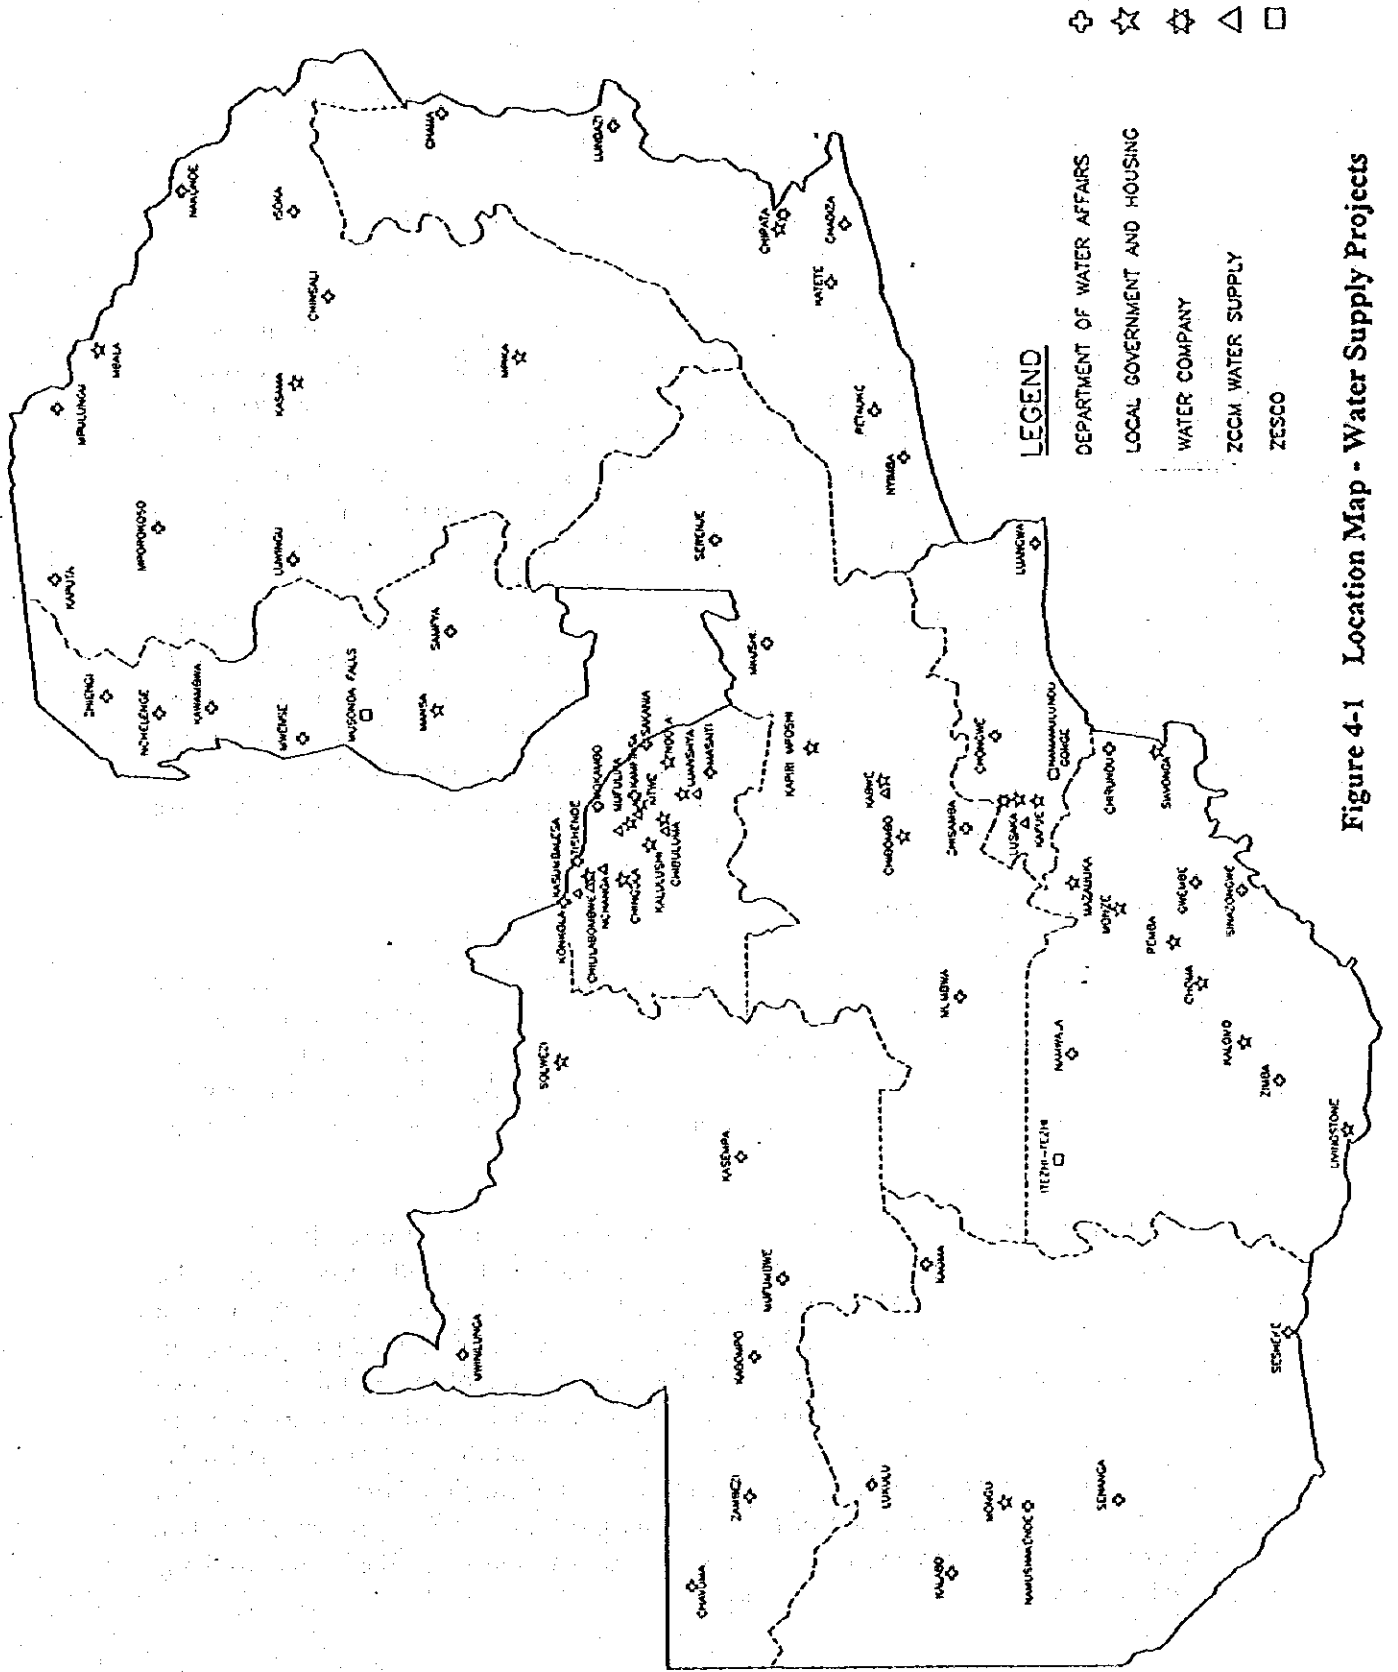

Although the records of existing Water Rights held in the WDB Registry are numbered as high as 5200, the actual number of record files found was only about 1830. In addition, a further 500 or so Water Right numbers were listed in the register but the location of the files for these records could not be determined. The procedure for Water Right application and allocation, and possible reasons for the high number of missing records, are discussed in Chapter 5.

The local consultant developed a database programme (dBase IV) to input the required data from the Water Rights records to computer. Analysis of the 1830 records was undertaken by the Study Team and corrections to the data were made where necessary. The results of the analysis are presented in Chapter 5 and a printout of the Water Rights database is included in Data Book 5.

4.2 Survey of Water Supply Projects

The main objectives of the survey of water supply projects were to compile a detailed inventory of all existing domestic water supply schemes, and to identify the current level of supply and condition of the facilities.

Domestic water supply projects in Zambia are currently managed by either DWA or local authorities, such as city, municipal or domestic councils, under the Ministry of Local Government and Housing (MLGH). In addition, there are two semi-autonomous water supply companies serving Lusaka and Chipata, and other water supply projects operated by ZCCM and ZESCO. Lists of known schemes were obtained from DWA and MLGH and a total of 85 water supply projects were identified. The number of projects operated by each of the managing bodies is summarised Table 4-1 and the location of the projects is shown in Figure 4-1.

Figure 4-1 Location Map - Water Supply Projects

Table 4-1 Number of Water Supply Projects

Managing Body	No. of Projects
DWA	46
Council	25
ZCCM	9
ZESCO	3
Water Co.	2
TOTAL	85

The local consultant was responsible for the distribution and collection of the survey questionnaire forms to all known managing bodies. A copy of the questionnaire form is included in the Appendix. In order to ensure the best possible response to the survey, the Study Team worked closely with the local consultant and letters of support from both DWA and MLGH were obtained to accompany the survey forms. The Study Team also forwarded the questionnaire to ZCCM management prior to the field survey trip to the Copperbelt, and distributed the forms to ZESCO managed schemes via the SADDCC Project Office.

As with the Water Rights records survey, the local consultant developed a database programme (dBase IV) to input the data from the completed questionnaire forms to computer. A total of 72 replies to the questionnaire survey were received from the 85 water supply projects identified - this represents a response rate of almost 85%. A list of the projects and analysis of the data from the questionnaire forms is included in Chapter 5. Summaries of the completed questionnaire forms received by the local consultant are included in Data Book 5.

4.3 Survey of Irrigation Projects

The survey of large scale governmental irrigation projects was included in the current water use survey to supplement a separate survey of Zambian farmers undertaken as part of the agriculture and irrigation sections of the Master Plan Study. A list of large scale irrigation projects was obtained from the Department of Agriculture (DOA) and questionnaire survey forms were sent to each of the schemes. A copy of the questionnaire is included in the Appendix.

From the list of ten large scale projects, replies to the questionnaire were received from six and the local consultant visited four of the schemes during the field survey trips. The irrigation projects visited were Mpongwe Developments in Central Province, Zambia Coffee at Kasama in Northern Province, and Kawambwa Tea and Mununshi Banana Estates in Luapula Province. In addition, the Study Team also visited some of these projects and also Nakambala Sugar Estates and Masstock Farm. The completed questionnaire forms were copied to the agriculture and irrigation experts for inclusion in those sections of the Study. The list of large scale irrigation projects and some key information from the replies are presented in Table 4-2. The location of the irrigation projects is shown in Figure 4-2. For the projects which did not reply to the questionnaire, estimates made by the local consultant have been included.

Table 4-2 Large Scale Irrigation Projects

Name of Project	Province	Water Use (m ³ /sec)	Source	Area (ha)	Crops
Nanga	Southern	1.75	Kafue River	600	1,2,3
Mpongwe	Central	0.97	Groundwater	1,300	3,4,2
Zambia Coffee	Northern	0.21	Lukupa River	174	2
Kawambwa Tea	Luapula	0.66	Luano River	453	5
Kaleya	Southern	0.25	Kafue River	250	6
Nakambala	Southern	12.74**	Kafue River	10,400	6
Masstock	Lusaka	1.25*	Kafue River	1,200	3,1
Gwembe	Southern	2.20*	Lake Kariba	2,200	---
Mununshi	Luapula	0.05*	Mununshi River	50	7
Mukompu	Copperbelt	---	---	---	---

Notes: Crops: 1 = cotton 2 = coffee 3 = wheat 4 = soybean 5 = tea 6 = sugarcane 7 = banana

* estimated by local consultant

** Nakambala Sugar Estates provides water to Kaleya Smallholders and Mazabuka council

The local consultant also obtained a list of small scale irrigation projects from the DOA and information on these projects was extracted from the ASIP report on the agricultural sector dated July 1994. Table 4-3 shows the list of small scale irrigation projects and the key data from the ASIP report.

Table 4-3 Small Scale Irrigation Projects

Name of Project	Province	Water Use (l/sec*)	Source	Area (ha)	Crops
Ikalenge	N/Western	210	Stream	300	Pineapples, coffee
Lukulu	Northern	2,100	River	3,000	Wheat, coffee, veg., citrus
Kaninga	Lusaka	20	Stream	20	Veg., maize
Mulumbi	Luapula	7	River	10	Vegetables
Mutambaule	Central	7	Stream	10	Veg., maize
Buleya Mulima	Southern	65.5	Lake Kariba	65.5	Veg., maize
Chapula	Copperbelt	14	Stream	20	Veg. citrus
Chipapa	Lusaka	10	Dam, River	10	Vegetables
Ipafu	Copperbelt	56	Stream	80	Veg., maize
Nkandawe	Southern	15	Dam	15	Veg., maize
Lukuzye	Eastern	3	Dam	3	Veg., maize
Siatwinda	Southern	18	Lake Kariba	18	Veg., maize
Vuu	Eastern	20	Dam	20	Veg. citrus
Lusowe	Eastern	5	Dam	5	Veg., maize

Note: Water use estimated by the local consultant based on average requirements of 1.0 l/sec/ha for Southern, Central, Western and Eastern Provinces; 0.7 l/sec/ha was used for other provinces. Water use shown represents the maximum usage if all areas are under irrigation.

Detailed analysis of the irrigation project questionnaires has not been undertaken as part of the current water use survey. For further information on agricultural water use, refer to the Supporting Reports on Agriculture and Irrigation.
