Chapter 2.

Review of Current Conditions

Chapter 2 Review of Current Conditions

2.1 Existing Sewerage/Sanitation and Drainage Systems

2.1.1 Sewerage Systems and Sanitation Facilities

(1) Sewerage Systems

There are four sewerage systems in operation in the study area, all of which are separate collection systems under MWSS supervision. These are the Central System, the Ayala System, the Dagat-Dagatan System, and the Quezon City Separate System. The service area coverage by the system at present is shown below.

Table 3.2.1 Existing Sewerage Systems in the Study Area

System	City/Municipality	Area (ha)	Remarks
Central System	Manila City	2,620	No treatment
Ayala System	Makati	600	
Dagat-Dagatan System	Caloocan, Malabon,	333	Only STP is
	Navotas, Manila		turned over to
		- 1	MWSS
Separate System	Quezon	1,000*	
Total		4,553	

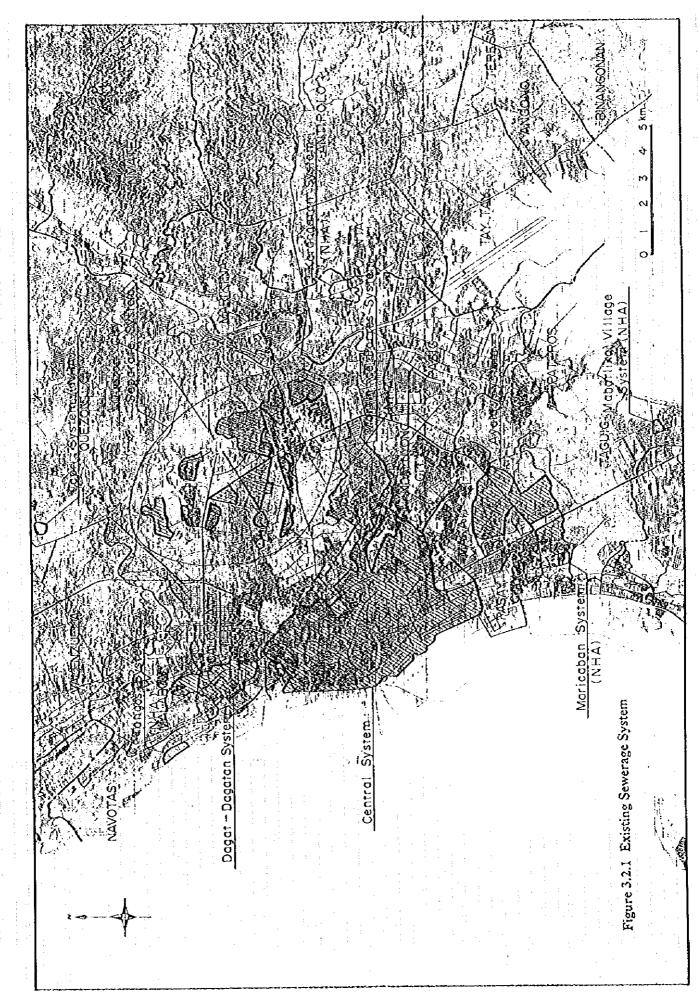

Source; MWSS

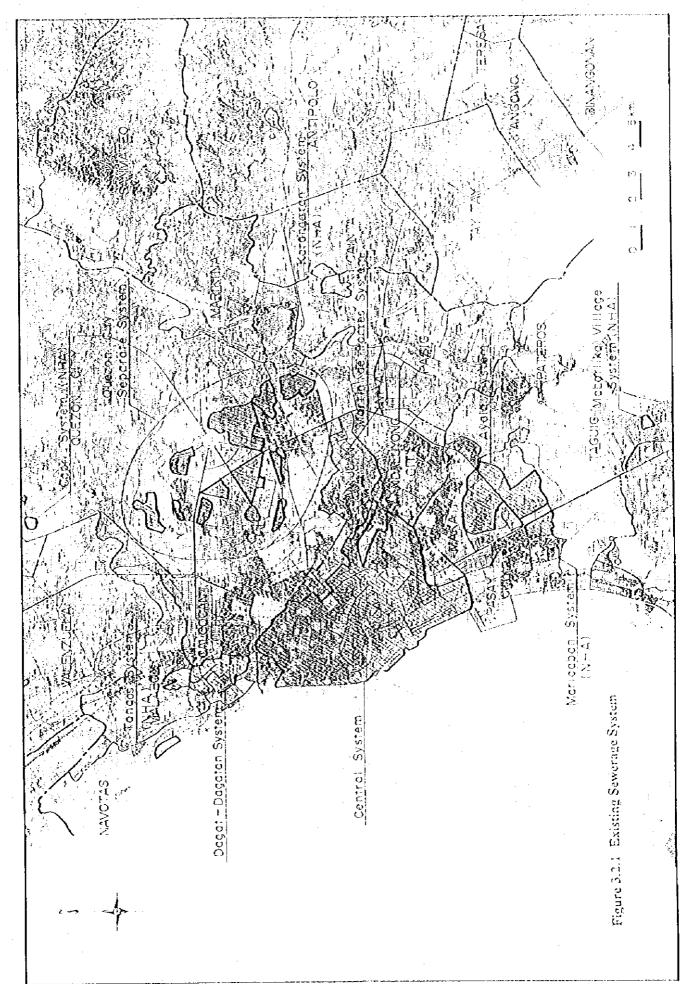

Location of each system together with the NHA (National Housing Authority) system is shown in Figure 3.2.1. Outline of each system is summarized in Table 3.2.2. From the above table, only 7 % (46 km²/636 km² = 7) of NCR is covered by sewerage system in areas.

As to the service coverage by respective sewerage systems, the number of household are 84,946 in Manila central collection system, 23,295 in Quezon city separate system and 3,009 in Ayala sewerage system. These systems serve for 111,250 households or about 900,000 persons in a total as of November 1994. Additional 100,000 persons projected for Dagat-Dagatan system increase overall served population up to 1,000,000 persons. However only 11 % of NCR population is accessible to the sewerage systems.

^{*} This figure is based on measurement on the map by study team

		Table 3.2.2	Table 3.2.2 Outline of the Existing Sewerage System	erage System

Remarks					

(2) Sanitation Facilities

3)

Within the study area, over 90% of NCR households has sanitary toilets with private septic tank, while Rizal and Cavite provinces mark less percentage of sanitary toilet facilities. According to the NSO statistics which classify the households by its kind of toilet facilities, water-scaled sanitary toilet is prevailing with 91 % of total households in NCR, 79 % in Rizal province and 84 % in Cavite province.

There are two types of septic tanks in accordance with the in-house plumbing system. One is the separate treatment type which receive only the night soil, in which case sullage is discharged directly into drainage system. The other is the combined treatment type which treat all the sewage. According to the DOH official, many households, especially those built 20~30 years ago, adopted the latter type. Drainage system sometimes directly receives effluent of the septic tank due to the poor absorption field and also sullage. This is why present drainage system is said to be "practically combined sewer system".

The number of the septic tanks was estimated by the projects assisted by ADB in 1991 and WB in 1994. They showed different figures assuming different family number per household. WB assisted project proposed the need of accurate research on the number and dimension of the septic tank in the early stage of septage management plan. The gross septic tank volume (including leaching pit) is estimated 6 m³, while effective septage storage capacity is 1.8m³, according to the ADB feasibility study.

(3) Operation and Maintenance works by MWSS

At present, there is no 0n-going sewerage system construction. MWSS is only engaged in the operation and maintenance of the existing facilities. Of the three divisions of Sewerage System Department (SSD), Operation and Maintenance Division participates in the cleaning of sewer pipes and manholes, operation and maintenance of sewage pumping stations. Sewer maintenance works has been accomplished extensively in recent years. However, the division has only one jet-cleaning machine and cleaning efficiency is low.

Desludging is one of the major works of the SSD. The work is performed in two different manners. One is septage collection and disposal by MWSS personnel on a request basis, and the

other is septage collection and disposal by Contractors on a regular work basis in a projected areas. These works are under the responsibilities of Septic Tank Maintenance Division, SSD. This division is also in charge of operation and maintenance of wastewater treatment plants, sewage quality analysis and monitoring.

They encountered the difficulties to ensure sludge disposal sites and in acquiring the ECC (Environmental Clearance Certificate). There is only one disposal site located in a stone quarry at Santa Rosa II near Marilao, Province of Bulacan, about 60 km far from the center of Metro Manila. The accomplishment of desludging in recent years is more than 4,000 households per year.

Third division of SSD, Sewer Connection Extension and Field Investigation Division, is responsible to 1) install and repair sewer mains and service connections, 2) conduct field investigations of existing systems and inspection of new collection system. This division is suffering from many unconnected service pipes, especially in Central System. The sewerage system developed by NHA is turned over to MWSS after the inspection and analysis by this division. Sewer maps and records are updated by this section.

2.1.2 Drainage System

In the study area, only Manila City had drainage plan, "Plan for the Drainage of Manila and Suburbs". The main drainage facilities in Manila and suburbs consist of open channels called "Esteros" and two types of box culvert, namely drainage main and outfalls. Outfalls are made of special culverts which connect to Manila Bay or Pasig River receiving wastewater from the Esteros. Other culverts function as drainage mains. In other areas creeks and laterals form main drainage systems. In 1990, DPWH in cooperation with JICA completed the master plan on flood control and drainage in Metro Manila to propose some effective projects.

Flood control, and operation and maintenance of main drainage in Metro Manila are managed by DPWH. LGUs (Local Government Units) are responsible for the small drainage facilities with the size less than 750 mm either in pipe diameter or width. The PMO(Project Management Office) for MMINUTE (Metro Manila Infrastructure, Utilities and Engineering) under DPWH and MMA are also undertaking small drainage projects in cooperation with Local Government. MWSS has not undertaken the drainage projects, except for the PROGRESS project in cooperation with MMINUTE.

2,2 Previous Studies Relevant to Sewerage/Sanitation Project

2.2.1 Sewerage and Sanitation Policy and Historical Circumstances

T

Philippine government issued "Water Supply, Sewerage and Sanitation Master Plan of the Philippines 1988-2000" and set up national target and investment plan. It was reviewed in the Medium-Term Philippine Development Plan (1993 ~ 1998).

On the Sewerage, the base figures in the Master Plan mainly come from "Sewerage and Sanitation Master Plan for Metro Manila" in 1979. This Sewerage and Sanitation Master plan has two major components; one is a sewerage expansion program for collection, treatment, and disposal in MMR entailing rehabilitation of existing facilities and other is monitoring system. This plan proposed 5-stage implementation program called METROSS. Present status of each stage targets are as follows.

Table 3.2.3 Conditions and Status of 1979 Master Plan Sewerage Projects

Stage	Period	Main Content	Project Status
METROSS-I	1981-1985	- Rehabilitation and Expansion of	This project is said to have been

		System covering separate sewer	commenced.
		system in part of Manila, Navotas,	
		Caloocan, Malabon and Quezon City.	
METROSS-IV &V	2001~	coverage in San Juan basin ,Laguna	This project is also not yet
		and Marikina basin with combined sewer system.	commenced.

The other component is sanitation program comprising 2 main items; PROGRESS - minor drainage projects for the depressed area and STAMP - septic tank desludging program. The part of PROGRESS and STAMPS were implemented as a component of METROSS - I.

Of the the components in 1979 Master Plan Project, METROSS II has been reviewed. In 1990, the scope of work of the ADB project covered some more components like integrated septic tank desludging work and formulated the Project called "Second Manila Sewerage Project. Based on the study results by the project, MWSS formulated "Manila Second Sewerage Project" in 1994

with financial assistance from WB, which does not include sewerage expansion scheme and mainly focused on septage management plan.

2.2.2 On-going Project of MWSS

Manila Second Sewerage Project (MSSP)

According to the draft final report, main components are 1) Septage management, 2) Ayala and Manila Central sewerage system upgrading, 3) Street drainage improvement, 4) Laboratory and equipment support, 5) Environmental Impact assessment, and 6) Institutional framework and financing. Among the components, the project focused on the septage management, and environmental, financial, and institutional study/analysis. Proposed project is described in Table 3.2.4 and 3.2.5.

2.2.3 Other Related Environmental Studies

The improvement of sewerage system and sanitation facilities are the major components of environmental improvement projects as considered by many government agencies. The provision of sewerage systems is an effective countermeasures to improve water environment and human health. In the past, various government agencies focused on a review of on-going (at that time) and proposed environmental improvement programs to give the priority for solution of environmental problems. Conditions and status of these studies/projects are summarized in Table 3.2.6.

Table 3.2.4 MSSP Sanitation Project Summary	Benefit Cost (in Million Pesos)	Cleaner environment resulting from (Phase 1) Construction of Pijot Septage Treatment the more effective function of septic tanks due to the removal of the Barging of Septage for Sea Dumping 155.32 Construction and Sea Dumping / Pijot Plant (Thase 2) Construction and expansion of septage from the septic tank (Phase 2) Construction and expansion of septage from the septic tank (Phase 2) Construction and expansion of septage from function of septage for Sea Dumping 155.32 Construction and expansion of septage from function of septage for Sea Dumping 155.32 Construction and expansion of septage for Sea Dumping 155.32 Construction and expansion of septage for Sea Dumping 155.32 Construction and expansion of septage for Sea Dumping 155.32 Construction of Seatage for Sea Dumping 155.32 Construction of Plate 15.12 Construction and Expansion of 3 STP 6,628.62	ted Only preliminary design was completed because this works was regarded as LGU-in-charge work

2.3 Water Pollution Status and Future Problems in Metro Manila River System

2.3.1 Present Water Pollution Analysis

(1) Run off Model of Pollution Load with Water Quality Checking Points

E isting sub-drainage basins are shown in Figure 3.2.2. This figure was prepared based on "The Study on Flood Control and Drainage Project in Metro Manila" conducted by JICA-study team in 1990. Sub-basin code names (PM-1,-2 etc.) are those used in the said Study. Figure 3.2.3 depicts the run-off model with checking points adopted in this study.

(2) Frame Values and Generated / Discharged Pollution Load by Sub-basin

a) Population

Population by sub-basin is calculated based on the 1990 population and population density by city/municipality, considering the locally concentrated population in some city/municipalities.

b) Domestic load

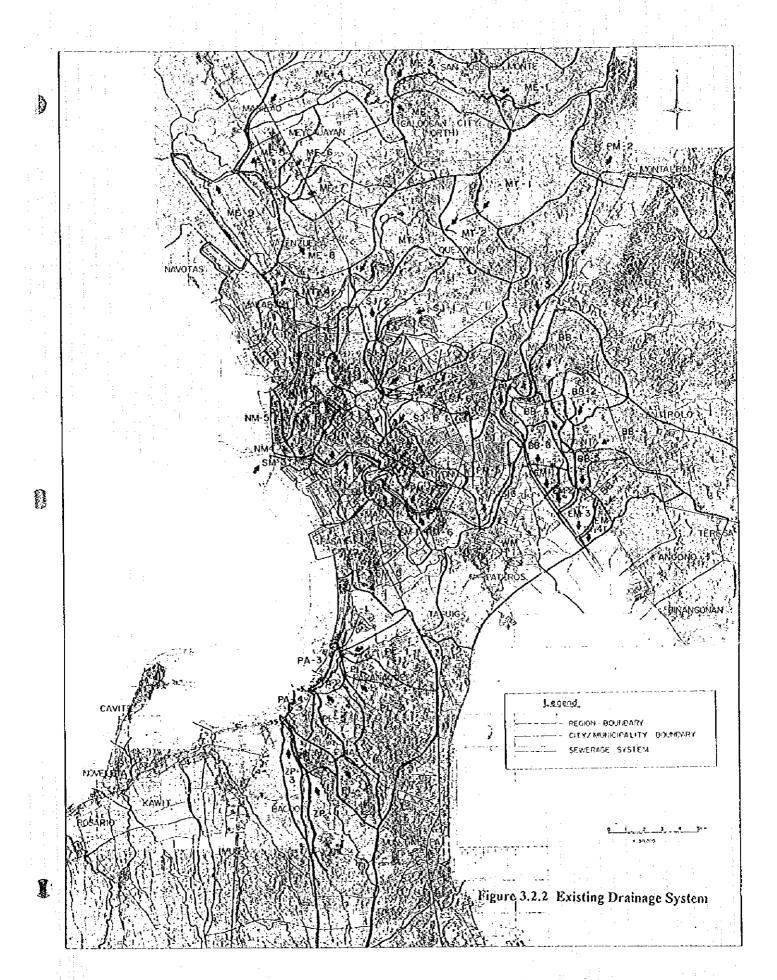

About 90% of the BOD load generated on-site is assumed to be discharged into public water body through the e isting sanitation facilities. Per capita BOD load is 40 g/day. Central System in Manila City discharges no BOD load into the river systems. Previous studies indicated that solid waste is also the cause of pollution with estimated BOD load of 6g/day/person equivalent to the 15% of the above-mentioned generated BOD load. In 2015, BOD generated on-site will increase to 50 g-BOD/day, but 6 g from waste will be reduced to zero.

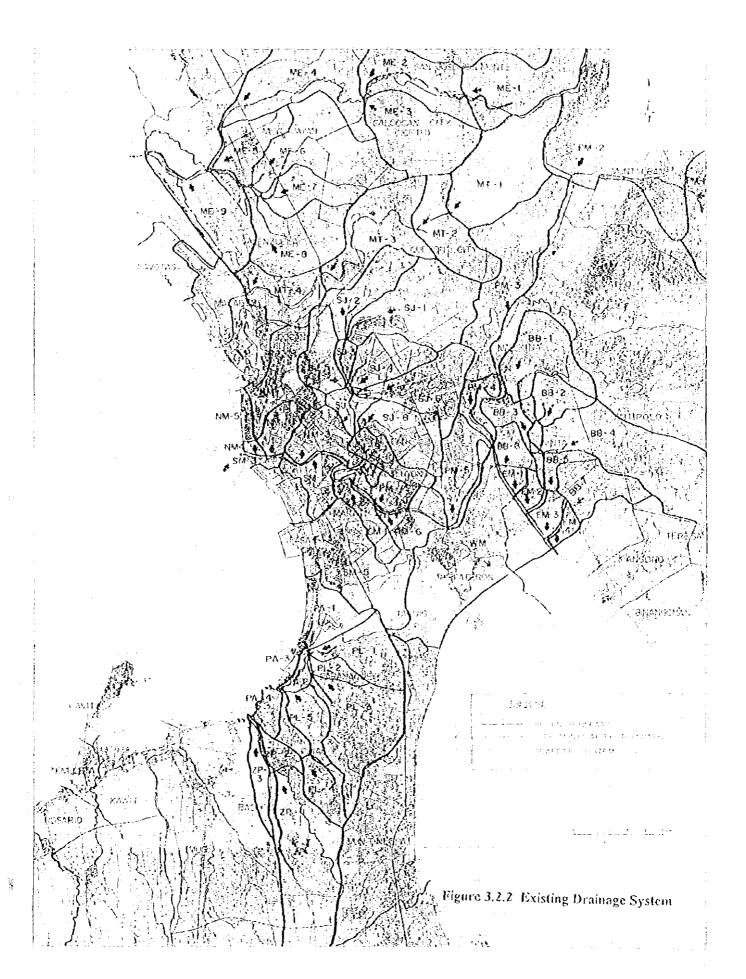

c) Industrial load

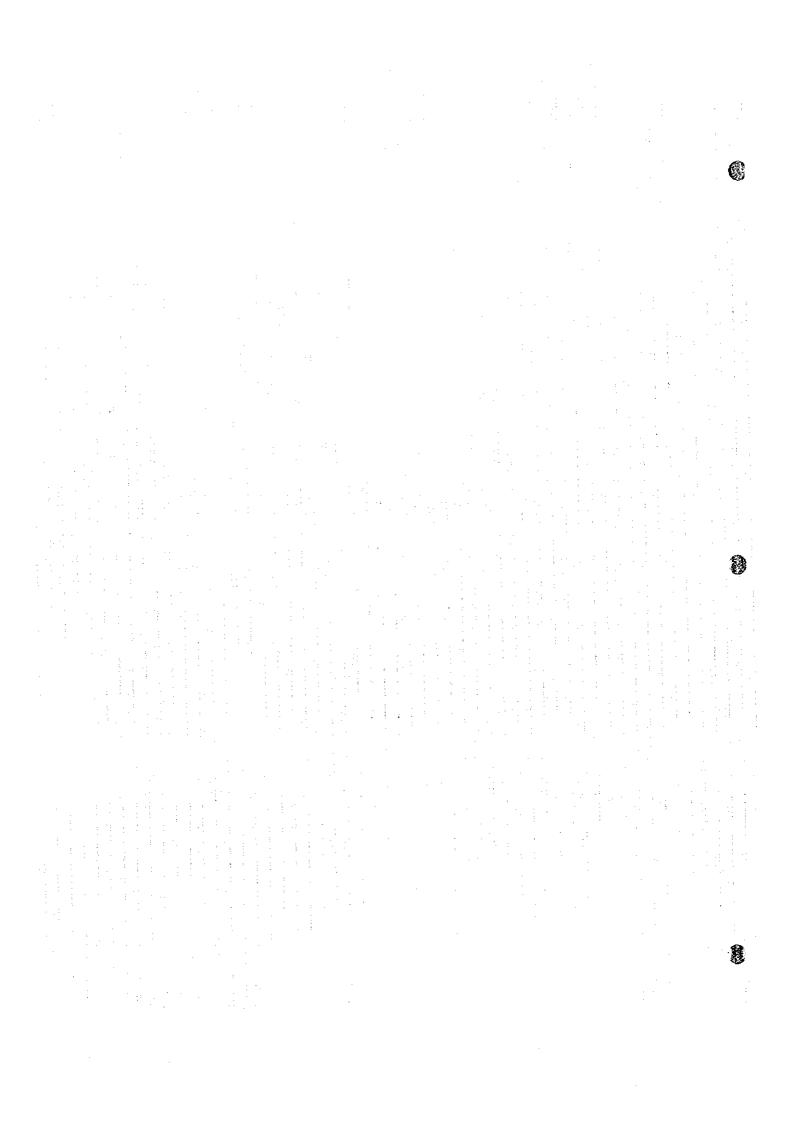

Information on industrial BOD-load discharge is referred to "Industrial Efficiency and Pollution Control Program (IEPC)" conducted by World Bank assisted project in 1992. According to the report the total discharged BOD load is estimated at 304 ton/day. This industrial BOD load is used for distribution to each sub basin.

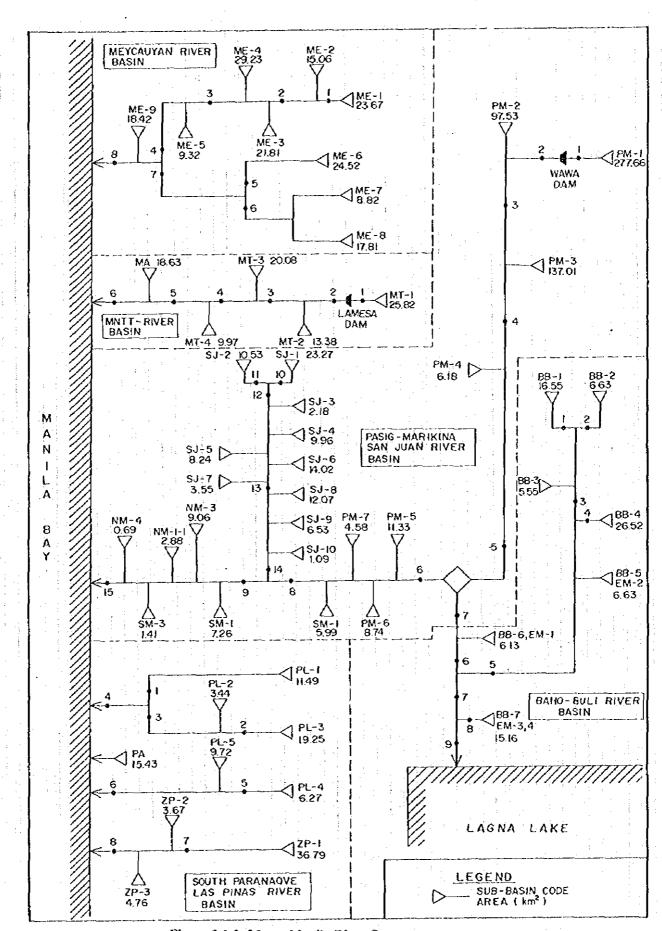

(3) Run-off ratio up to checkpoint

Total run-off ratio is defined as a combined factor of concentration ratio and a remaining ratio after river self-purification.

)

Figure 3.2.3 Metro Manila River System

Based on the experience in Japan, following concentration ratios are commonly adopted for the water pollution control study.

Land use type	Concentration ratio	Remarks
Rural area	0.0 - 0.20	
Urban area		The ratio is dependent on
1) med -low pop density	0.1 - 0.60	the arrangement status of
2) high pop.density	0.6 - 1.00	drainage facilities
Sewerage system	1.00	

Self-purification ratio of the river is difficult to decide without field confirmation. In this study, the total run-off ratio is set up as follows. Industrial farms are usually situated in the vicinity of the rivers and their run-off rate is generally higher than residential area.

Domestic BOD run-off ratio	0.2
Industrial BOD run-off ratio	0.6

(4) River Flow

River flow data come from the "Philippine Water Resources Summary Data (Volume. 2 - Streamflow and Lake or River Stage Ending December 31, 1980)". Only the Marikina River is gauged in Metro Manila Region, of which two points data can be represented in the unit of cu.m/sec. Other data are shown in terms of gauge level. These two points are Sto. Nino, Marikina, Metro Manila and San. Rafael, Montalban, Rizal. From the Sto. Nino data, the specific flow factor (SFF) in m³/sec/km² is calculated using the yearly average data. The drainage area is 499 km² and the flow is 19.5 cu.m/sec in year round, which calculates to be 0.039 m³/sec/km² as a specific flow factor.

(5) Water quality estimation

Water quality in terms of BOD at each checking point is calculated from following formula;

$$C(mg/l) = \frac{\Sigma \text{ Domestic discharged BOD load (kg/d)} \times 0.2 + \Sigma \text{ Industrial discharged BOD (kg/d)} \times 0.6}{\Sigma \text{ River basin area (km²)} \times 0.039 \text{ (m3/sec/km²)}} \times 10^{3+86400}$$

Water quality at each point is shown in Table 3.2.7.

2.3.2 Future Water Pollution Analysis

Without any countermeasures, the water quality will become worse in proportion to the economic development. Water quality in target year 2015 is estimated using the same method assuming that future industrial BOD load will be constant. Industrial expansion is likely to happen outside

of MMR. As a reference, future condition with IEPC countermeasures is considered. IEPC strategy is industrial pollutive load abatement through waste minimization/clean technology and wastewater common/individual treatment. It reduces future 573 ton/day discharged loads to 130 ton/day. In this report calculation, IECP target is assumed to be accomplished in 2015 to 130 ton/day from e isting value. Future water quality is shown in Table 3.2.7

Chapter 3.

Mater Plan

Chapter 3. Master Plan

- 3.1 Basic Policy and Conditions for Preparation of Sewerage/Sanitation Master Plan
- 3.1.1 Type of Plan, Definition and Basic Policy
- (1) Type of plan and its definition in this study

a. Framework Plan

This plan establishes the development policy for the entire study area, such as the detailed demarcation of both the on-site treatment (without sewer system) area and the off-site areas (with sewer system). Although the target year for this plan is not fixed, the data projected for 2015 are utilized for the purpose of this plan. The Sewerage Framework Plan will cover the off-site treatment area, while the sanitation study will cover the entire study area because of the existing sanitation situation prevailing.

b. Master Plan

This Sewerage Master Plan embraces the long term sewerage development plan of the off-site treatment area up to the year 2015. Considering that the off-site treatment area, as defined in the Framework Plan, seems difficult to be fully covered in this study, the Sewerage Master Plan area will be selected based on social, economic and environmental priorities. Also, to be considered would be location, structure, capacity, staged construction, and the financial plan of the main facilities.

For the sanitation sector, a long-term septage management plan was completed last year. Since the target year and area of said plan was set at 2010 covering the NCR, an adjustment for target year and coverage area for this study should be made.

c. Staged Development Plan

This master plan, being a long term plan, entails a huge cost. It would be best to divide this development plan into several stages to be able to better manage the plan's physical and cost requirements. It is expected that by mid-stage, the on-site and off-site treatment will materialize.

(2) Common basic policy of each plan

a. Utilization of existing facility/system

The basic policy is to build a financially realistic plan based on a low cost sewerage/sanitation system. Thus, the existing sewerage and sanitation facilities and system, such as the "practical combined sewer system" should be more efficiently utilized. The use of the septic tank as an alternative to being connected to the sewerage system is most likely to continue, particularly in those areas not covered by said sewerage system.

b. Cooperation with related sectors

The development cost of a new sewerage and sanitation system can be further reduced by the utilization of private sector systems like the Ayala System or the adoption of a BOT scheme. The promotion of a communal treatment system or the installation of an upgraded on-site treatment facility can also be enforced by government through city planning, land use, and building construction regulations. Public consciousness on the importance of sewerage and sanitation facilities and practices should be enhanced by LGU community participation.

c. Balanced development of water supply and sewerage/sanitation

A well-balanced development between water supply level (level I, II and III) and sewerage/sanitation facilities has been emphasized recently. In case water supply precede without appropriate sewerage/sanitation facilities, increased sewage may cause degradation of the water environment. In Metro Manila, where septic tanks are commonly used and the majority of them are adopting the combined treatment of household sewage, increased volume of sewage is likely to flush-out untreated nigh soil into the drainage.

According to the Sanitation Code, however, capacity of septic tank is determined based on the unit volume of 50 gallons per capita per day (= 190 lpcd) and standard septic tank can be suited water supply of Level III as long as it is maintained in good condition. Regular desludging is indispensable from this point of view. As is described in the MSSP report, the priority of desludging is put on the households which receive water supply from the central distribution system and bear an environment tax.

It is recommended that MWSS will survey the sanitation facilities of the household when they apply for a water connection. If the facilities are not appropriate, MWSS should give guidance for the improvement of the facilities.

d Cooperated development of sewerage and sanitation facility

"Human health" and "environmental protection" are the two major target of sewerage/sanitation sector. In this Master Plan, improvement of human health is mainly shouldered by the development and appropriate management of sanitation facilities. Sewerage aims at water environment protection. The reason for this originates following facts;

- The latest Manila Second Sewerage Project focused on the management of sanitation facility
 to improve Metro Manila sanitary condition. This project contribute to the improvement of
 human health by reducing human contact with the sewage.
- The low cost combined system (interceptor system) proposed by the ADB consultant in 1991
 and also approved in the MSSP report can improve the water environment but cannot
 directly contribute to the human health as far as the sewer network is not developed.

3.1.2 Target Level

There are two target levels that will be considered. The first is the target level that the MWSS can undertake by itself. These are sewer access rate (service coverage), effluent quality of the treatment plant, septage desludging and others. The second is the target level that the MWSS can accomplish with the cooperation of related agencies. An example of this is keeping the environmental standard for the public water body quality. The main items were discussed between the Study Team and the MWSS counterparts and target levels were limited to a few items described in Table 3.3.1. The details are as follows:

(1) Sewerage

a. Sewer access rate (service coverage)

This is critical considering the possible investment up to the target year. In the National Plan, it is said that completion of METROSS-II will increase the sewer access rate to 14%, METROSS-III to 24%. The maximum rate may be around 30% due to the adoption of an inexpensive interceptor system. In case the combined system is adopted, the sewer access rate may be changed to the service coverage or to the beneficial population rate.

b. Effluent quality from treatment plant

With appropriate O&M, the conventional sewage treatment plant can achieve a 30 mg/l of BOD₅, 40 mg/l of SS. The DENR-EMB effluent standard is 50 mg/l of BOD₅, so this target level seems appropriate. In the MSSP, this target level has also been adopted.

Table 3.3.1 Target Level

Сатедогу	Item	Existing	Target	Remark		
Sanitation	Regular destudging of septic tank	once in more than 15 years in NCR	once in 5 to 10 years in target year 2015 in Level III supply area	projection from 2010 to 2015 is necessary. because MSSP covers up to 2010		
Sewerage	Sewer access rate(service coverage)	less than 10% of NCR	nearly 30% of MWSS jurisdiction	depend on cost constraints		
·	Effluent quality from treatment plant	Ayala WW11 ² discharge over 65 mg/I BOD con.	Effluent ;less than 30 mg/t to all proposed treatment plant	Ayala WWIP is likely to clear effluent standard after the MSSP		

(2) Sanitation

a. Use of Sanitary toilets.

Attaining a rate of 100 % on the use of sanitary toilet (water sealed toilet) is the final goal. However, this sanitation facility is installed at the owners expense, while the DOH is responsible for regulations regarding septic tank.

b. Regular desludging and septic tank effluent quality.

It is reported that a 32 liter/cap/yr of sludge is accumulated in each individual septic tank in Metro Manila (WHO report says it is 30 - 40 liter/cap/yr). If 1.8 m³ is supposed to be the effective volume of storage capacity, maximum desludging interval is calculated as follows:

1800 liter / 5 persons x 32 liter/ per /yr = 11 year

The MSSP was developed targeting 0.7 million households now supplied water by MWSS at Level III to be desludged at a cycle of once in every 5 to 10 years. This level should be applied to all the Level III aracs in 2015.

c. Public toilets.

Two public sanitary facilities were completed in the METROSS-I project. At present, however, MWSS has no intention of constructing public toilets.

d. Others

Upgrading of septic tank

Even if septic tanks are regularly desludged, any overflow of existing septic tank contains high BOD concentration and thus upgrading is recommended. The two options available are to standardize material and structure and to adopt a combined treatment of sullage and night soil. This can fall under the responsibility of the DOH.

(3) Environment

a. Water quality standard attainment rate

At present, all the rivers in the Metro Manila Region are classified into "Class C" except the upper stream of the Marikina River.

Class C demands a 10 mg/l of BOD concentration. The existing concentration is far above this standard and its rapid attainment would be very difficult. A simplified analysis of the BOD load distribution and its influence on the main river system in MMR are investigated and future degradation is forecasted. An interim standard may be adopted as the target aim of the related agencies, MWSS, DPWH, DOH, MMDA and LGUs.

For example, one proposal is the following table:

Table 3,3.2 Recommended Staged Target Level of Class "C"

Stage	1st stage	2nd stage	3rd stage	DENR-standard
Target year	2010	2015	2020	
BODcon. (mg/L)	30	25	20	10 mg /L

(4) Drainage

a. Safety probability in return period

DPWH is responsible for flood control and the main drainage system in the Philippines. But in case the MWSS constructs an interceptor pipe adopting the combined system into the sewer system, its design standard needs to meet the DPWH requirement. The probability of this happening is from five to ten years.

Since inland flooding is one of bigger problems in this country, a comprehensive run-off drainage plan that includes rivers, drainage, gutters and the sewerage system is required. This will clearly define the role and coverage of flood control and drainage, where flood control will flow through the river systems, and drainage control through the sewerage system.

b. Street drainage

In METROSS-I, a street drainage program was completed as PROGRESS. This was aimed at reducing human contact with stagnant sewage, especially at residential and depressed areas.

As for the MSSP, the original TOR includes street drainage as one of its components, but this was deferred for lack of budget sources and the uncertainty as to who the supervising agency would be for the project. The LGUs and DPWH (under the MMINUTE project) are both related agencies.

3.1.3 Basic Frame of the Plan

(1) Target Year

The target year for the total study, including that of water supply, is 2015, while MSSP aims for 2010 as its target year. Although this Master Plan conforms to 2015 as its target year, a periodic review is, however, mandatory to respond effectively to the social structural and other changes.

(2) Target Area

The entire study area is first divided into the Framework Plan area for both off-site and on-site treatment. Then the off-site treatment area (Sewerage Framework Plan area) is divided into the 2015 Master Plan area and the "future coverage area" in the latter section.

(3) Service Population

The total population within the study area for the target year of 2015 comes from project framework. This is further divided by each planning area in the latter section.

(4) Combined treatment of industrial wastewater and domestic/commercial wastewater

Before estimating the wastewater generated in the study area, an investigation should be conducted as to whether the combined treatment of industrial wastewater and domestic / commercial wastewater is allowed or not, as criteria on planning and designing varies according to its allowance or non-allowance.

1) Existing conditions.

The current policy of MWSS is not to accept any industrial wastewater into the sanitary sewers.

Resolution 75 -71, Sewer use Regulations adopted by MWSS in 1971 is still valid.

Actually, the existing industrial firms located along the existing sewer line in the Central Sewerage System in Manila City are not allowed to discharge their wastewater into the sewer pipe and only the domestic wastewater of the industrial complexes are allowed into the sanitary sewers.

The reason is that industrial wastewater is usually highly pollutive in both BOD and toxichazardous load and these pollutants affect the function of sewerage facilities, especially biological treatment. There is also no system to check just exactly how pollutive the industrial wastewater is.

On the contrary, the 1979 Master Plan admitted allowance on condition that an industrial wastewater management program would be implemented, where new administrative organization and industrial waste regulations are proposed before allowing industrial wastewater into the sewerage system. The reasons for this recommendation are:

- 1. Industrial wastewater volume is only 12% of total wastewater volume discharged from MMR and has little effect on the sewer pipe size.
- 2. BOD loads amounts to 40% of total discharge load but it only affects secondary treatment (biological treatment) which will be adopted in some uncertain future.
- 3. Individual treatment cost may be a big burden to small firms.

2) Recommendation

Basically, industrial wastewater should be prohibited or not allowed into sewer system and individual or common treatment is to be promoted for the following reasons.

- 1. The MWSS and DENR policy on industrial wastewater prohibits it into the sewer system.

 The main purpose of the sewerage system should be focused on domestic wastewater.
- 2. The BOD loads of industrial wastewater in raw (not treated) BOD level, amounts to 53% of total BOD, while domestic wastewater accounts for 30%, and solid waste to 17% according to IEPC data. Sooner or later, secondary treatment of the sewage will be necessary for the protection of the environment and such a high percentage of industrial BOD loads require treatment high cost. The sewerage system should, therefore be constructed mainly for domestic wastewater.
- The IEPC project is now being implemented by DENR and it does not consider allowing industrial wastewater because rapid sewerage expansion is not expected.

- 4. The existing effluent standard of the DENR/EMB should be respected and if this standard is strictly observed, treated wastewater can be discharged into the river system.
- 5. In NEDA Board Resolution No.5, treatment of industrial wastewater should comply with the effluent standard.

(5) Wastewater Volume and Quality

Wastewater volume is initially calculated by city/municipality and also by the type of wastewater - domestic, commercial, or industrial wastewater.

The major wastewater sources identified in the study area are domestic, commercial, business, institutional and industrial wastewater as point sources. Other pollution sources, such as agricultural and natural are not covered in this study.

Wastewater quantity was estimated, in principle, using the data on water consumption or discharged wastewater volume on a measurement basis and the type of wastewater in accordance with water supply study. Classifications are (1) domestic wastewater, (2) commercial wastewater (including business/institutional) and (3) industrial wastewater. Wastewater quality for the planning purposes is limited to BOD loading as a representative index of the organic substances. In addition to the above classification, the infiltration rate was considered.

The unit BOD loading from different pollution sources was estimated based on the investigation results conducted by the concerned agencies in the Philippines, with reference to experience in Japan and other countries.

a. Domestic wastewater

1) Unit Quantity

With regard to the per capita water consumption rate, the projection until the target year of 2015 was conducted from water supply side of this study by the city/municipality. The unit wastewater discharged rate (lpcd) is usually regarded as equal the water consumption rate in case infiltration of groundwater is included, and as 70 to 80% of water consumption rate when infiltration volume is taken into as another unit volume. There is no available data on the breakdown of water consumption, so 70% was adopted, as considered in the Second Manila Sewerage Project in 1990 by ADB, and also in the MSSP in 1994 by the WB consultant.

The unit volume of each city/municipality in 2015 is summarized in Table 3.3.6.

The unit consumption rate in some previous studies was estimated by population density or income level. In this study, however, this method is not adopted because population density projection by area is difficult due to the unavailability of local population data. This should be given consideration in the F/S or D/D stage. Water quantity from public faucet use is negligible.

2) Unit BOD load

In the 1979 Master Plan, the following figure was recommended after giving due consideration to the previous master plan, the LLDA report, and other data.

Table 3.3.3 1979 Master Plan Unit Load

BOD ₅ (gram/cap/d	ay)	SS (gram/cap/day)		N	P
	tal	Domestic	Total	gram/cap/day	gram/cap/day
50 75		50	75	12	2

Total includes commercial, institutional and industrial load.

In the Pasig River Rehabilitation Project, the reported per capita BOD load for the different income group was as follows, as of 1991:

High-income group
Middle-income group
Low-income group
S3 g / Day
40 g / Day
25 g / Day

In the Environmental Management Strategy report, the World Bank consultant assumed that 35 g /cap/day of BOD is generated on the average. In Japan, an average figure on this subject is more or less 50 gpcd at present (night soil, 15-18 gpcd and sullage, 32-39).

For this study, a total of 40 gpcd (generated base) may be employed as the base year figure in 1995, broken down into night soil, 10 gpcd, and sullage, 30 gpcd. For future projections, an annual increase of 0.5 gpcd in sullage will be utilized, while the night soil load is assumed to be constant.

Table 3.3.4 BOD load of Domestic Wastewater

	<u> </u>	1995	2000	2005	2010	2015
	Sullage	30	32.5	35	37.5	40
BOD	Night Soil	10	10	10	10	10
(gpcd)	Total	40	42.5	45	47.5	50

b. Commercial Wastewater

Commercial wastewater is also basically calculated from water supply projections. The discharge ratio is assumed to be 70% as same as that of domestic water.

Commercial water use is projected by city/municipality in supporting report. This figure is computed with the assumption that half the volume of the commercial areas where the groundwater source is saline will be connected to the central water distribution system. However, ground water volume assumed not to be converted to tap water is also included in total commercial volume. Table 3.1.6 shows total commercial wastewater volume in the target year of 2015.

Water quality of commercial wastewater is assumed to be the same as that of domestic wastewater.

c. Industrial Wastewater

Although industrial wastewater is not allowed into sewer system, its volume and water quality were investigated, the results of which are in supporting report.

d. Infiltration rate

The groundwater infiltration rate is taken into account by two ways:

- (1) some percentage of wastewater discharged into sewer system
- (2) constant infiltration rate per hectare per day

In case of adopting (1), 10% - 20% of daily maximum wastewater is employed considering the rain fall, ground water level, pipe joints and others.

MWSS has long adopted (2) method shown in following table

Table 3.3.5 infiltration rate in previous study

and the second s	A HOSC DIDIO	111111111111111111111111111111111111111		
Type	1979 Master Plan	1991 Second Manila	1994 Manila Second	MWSS Design
		Sewerage Project P/S	Sewerage Project	Standard of Design
			(Street Drainage)	Department
Existing System	37.5 m³/ha/d	35 m³/ha/d	40 m³/ha/d	
New System	15 m³/ha/d	15 m³/h2/d	15 in ³ /ha/d	0.2 1/s/ha
				(17 m³/ha/d)

Under the following assumption, the infiltration ratio against total wastewater is 27%, which seems a bit high.

```
(Assumption) population density = 300 persons/ha, per capita water use = 200\text{m}\text{I/d}, commercial/industrial ratio = 0.3 of domestic wastewater, wastewater convert rate = 0.7, so Q = 300 \times 0.200 \times 1.3 \times 0.7 = 54.6 \text{ m}\text{3/ha/d}, ratio of Infiltration/sewage = 15/54.6 = 0.27
```

But considering the local construction skills, materials, climate conditions and O&M levels, the existing rate is adaptable in this plan. Quality control of the pipe material, fitting and pipe laying technic should be reviewed to prevent excessive infiltration.

e. Peak factor

Peak factor has two meanings. One is peak day flow factor which is the ratio of maximum daily flow against average daily flow and is usually used for treatment plant capacity design. The other is peak hour flow factor which is the ratio of maximum hourly flow against average daily flow, which will be used to decide sewer pipe capacity. In the past report, latter factor was decided by the Babbit Formula and this is the standard that MWSS also uses.

 $M = 5/P^{0.2}$; where P is population in thousand. In this study, the peak daily flow factor is assumed to be 1.25 and peak hourly flow factor is 1.75 in accordance with the water supply design.

F. Total Wastewater Volume

1) wastewater volume

The calculation of the daily average wastewater volume by each city/municipality for the year 2015 is contained in Table 3.3.6 and Figure 3.3.1. In this table, domestic wastewater is assumed to come only from central distribution system as wastewater from public faucet is negligible. The catchment area-based wastewater volume and quality will be recalculated after the demarcation of the on-site and off-site treatment areas.

G. Influent wastewater quality

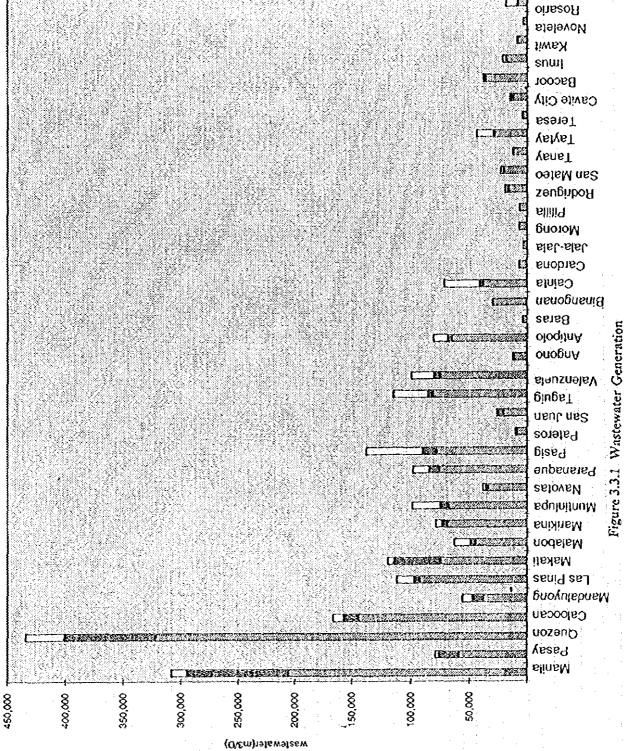

Wastewater quality is the fundamental data for the calculation of the capacity of the wastewater treatment plant. It can be calculated from total discharged load and total wastewater, but for this master plan, it is decided as follows, with consideration of the existing plants' data and other data.

BOD(mg/l); 200, SS(mg/l); 200

Table 3.3.6 Wastewater Volume

3.1.4 Framework Plan Area

The objective of this section is to break up MWSS's jurisdiction into two areas:

- (1) The area covered by Sewerage (Off-site treatment area)
- (2) The area covered by Sanitation facility (On-site treatment area)

It should be noted, however, that these areas have not been clearly subdivided at the intermediate stage especially in the case that a combined system or a small-bore sewerage is adopted. The former starts with an interceptor system with the use of individual septic tanks as sanitation facilities in unserved areas; while the latter receives the effluent of septic tank into the sewerage system.

The sanitation coverage under the MSSP septage management plan covers all of the NCR up to the year 2010. This coverage may require review. The criteria for coming up with the demarcation are the development plan (land use), population trend, environmental impact factor, construction cost and water supply level.

Population density and construction cost

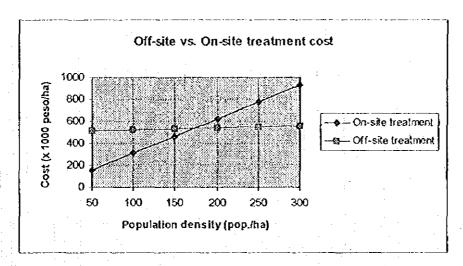

These are closely interrelated, thus this can be estimated using the following calculation:

(assumed condition)

- Population density (1) 100 persons / ha, (2) 180, (3) 300
- Number of persons per household 5 persons
- Household density (1) 20 hh/ ha, (2) 36, (3) 60
- Pipe-installation density 200 m / ha
- Pipe-installation cost 2000 pesos/meter
- Construction cost of Sanitary toilet with septic tank 15,500 pesos / households (DOH data)
- Lateral Pipe cost(house connection) 1,000 pesos/ household

	On site treatment	l: : ; ;		Off-site treatment			
1 1 1	(1) 100 pop/ha	(2) 180	(3)300	(1) 100 pop/ha	(2) 180	(3) 300	
Pipe installation				Sewerpipe 200*2,500= 500,000 pcsos <u>Lateralpipe</u> 20*1,000=20,000 pcsos <u>Total</u> 520,000 pcsos	pipe 200*2,500 = 500,000 Lateral 36*1,000= 36,000 Total 536,000	pipe 200*2,500 = 500,000 Lateral 60*1,000= 60,000 Total 560,000	
Treatment facility Total	20° 15,500 = 310,000 pesos /ha 310,000 pesos /ha	36* 15,500 = 558,000 558,000	60* 15,500 = 930,000 930,000	neglect 520,000 pesos Tha	neglect 536,000	neglect 560,000	

If all other conditions other than population density are the same, the off-site system is more economical when population is over 180 persons/ha. Considering the cost of an off-site treatment facility, a threshold of 200 persons/ha can be used.

Development (land use)

Build-up areas, commercial areas in the future land use map projected in Part I are the priority areas of off-site treatment. Large-scale developments like Fort Bonifacio will be included in the area covered by the sewerage system. Basically, development trends are reflected into population and commercial water consumption increases in each city/municipality

Environment impact

From the estimates of future river water degradation, the San Juan and NMTT river basins, North and South of Manila, Las Pinas and the left bank of the Marikina areas have high degrees of influence on water pollution. The impact on Laguna Lake requires early sewerage coverage over lake basin areas in the NCR and Rizal where development areas are linked with the NCR.

Water Supply Level

1

The central Distribution System (Level III) is expected to expand to cover 90% of population in MWSS jurisdiction by 2015.

Sewerage areas decided from the above factors are shown in Figure 3.3.9 and Table 3.3.7. These cover almost the same areas as the 1979 master plan area except for Muntinlupa and the Manila Bay Reclamation Areas.

3.2 Development Plan on Sewerage

3.2.1 Wastewater Collection System

(1) Alternative collection system

Two alternative collection systems, separate and combined, were comparatively studied. The characteristics of the two systems are summarized as follows:

Alternative 1. Separate system

A separate system has a parallel collection system for sanitary sewage and storm water run-off, respectively. This system is more advantageous as the surrounding sanitation environment is improved and water pollution is more controlled than in the combined system. This system is more suitable for areas where water pollution is strictly prohibited. It is also recommended in areas where conventional drainage facilities are well maintained and where enough space for the sanitary sewer facilities can be secured. Covering a new development area with separate system is also recommended because of the nuisance involved in the collection of night soil. Furthermore, land values go up wherever the living environment improves.

On the other hand, the collection of sanitary sewage requires construction of lateral sewer pipes and house connections which makes its cost very prohibitive.

Alternative 2. Combined system

A combined system is one that collects sanitary sewage and storm water run-off by means of one combined sewer. The Southeast Asian version of a combined system is the utilization of an existing waterway as a practical combined sewer for storm run-off, sullage, and for overflows from the septic tank. This combined sewage is initially converted in the interceptor sewer via an overflow structure. The advantage of this system is that the interceptor system is used only in the initial stage to save on cost while a sub-catchment area system is being flexibly developed. In adopting the interceptor system, the following conditions are required.

- 1) Existing drainage/channels presently collecting rainwater and sullage (miscellaneous waste water) can be used as combined sewers on a semi-permanent basis.
- 2) Discharge of diluted wastewater into a public water body is acceptable during rainy season.
- 3) Night soil is properly disposed of at the generated site.

This combined (interceptor) system contributes to water quality improvement and costs less than a separate system at the initial stage. But the surrounding environment will not improve unless a sub-catchment area is covered by the sewer network.

Other points to be observed are enumerated below:

1) Improvement and expansion of existing drainage systems

Existing waterways now functioning as drainage systems are not necessarily sufficient at the present time against storm water run-off. Such waterways may be used as receiving water bodies of overflow water from the diversion chamber in the areas served by the sewerage system. However, the improvement (dredging and widening of channels) and expansion of the existing drainage facilities shall be done in accordance with the arrangement by the LGUs as practiced in Metro Manila.

2) Proper operation and maintenance of septic tank by means of Septage Management Plan and solid waste disposal

The adopted sewerage system cannot be completed without proper treatment and disposal of night soil. Regular desludging of septic tanks and treatment of collected septage are the main components of the MSSP. Information dissemination and legislative measures on the design and construction of the facilities should be undertaken by the LGUs. Arrangements for desludging the facilities shall also be provided properly as well as sound disposal of the sludge. In addition, the present refuse collection and disposal shall be improved to cover sewerage service areas in order that sanitary landfill/composting can be performed.

3) Maintenance of overflow/diversion chamber to keep the function of adopted sewerage system. Aside from the design of the contrived chambers, periodic maintenance of the facilities, especially systematic solid waste removal, is essential. The function of the sewerage system depends on adequate arrangement by concerned agencies and cooperation of the beneficiaries.

4) Provision of house connections pipes to connect to overflow pipes of night soil treatment facilities

With reference to planned grade of the interceptor and overflow structure, it is difficult for the beneficiaries to realize an immediate improvement of living conditions. The collection and

treatment of overflow water from septic tanks could contribute to the improvement of the water quality in the channels in the urban area/sewerage service area. Priority will be given to the selected locations within the sewerage service area with the installation of such connection pipes to interceptors where sewage fees will be charged.

(2) Adoption to this study area

*

The major factors to be taken into account in the selection of wastewater collection system are as follows:

- 1) Saving on construction cost for the sewer network is a major concern of the Government, as well as utilizing existing channels in the built-up areas. Drainage construction is under LGU/DPWH and coordination is required.
- 2) On-site sanitation facilities are widespread in the study area and recognized as a positive alternative for the sewerage system, thus, it would be best and practicable to continue using relevant existing facilities.
- 3) Although under the first stage of the combined collection system, water pollution in the channel caused by the discharge of sullage from house would not improve by using the current drainage system, water quality in the main river downstream of the built-up area will considerably improve.

With an emphasis on the low cost construction in order to realize sanitation/public water body quality improvement at a service level affordable at the present time in Metro Manila, the combined system is recommended as a structural frame.

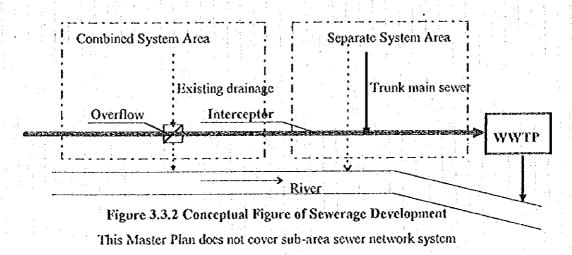

Figure 3.3.4 is the conceptual drawing of staged improvement of combined wastewater collection system. This master plan aims to secure the STEP 2 level and the development and improvement of high priority areas.

As to the development of each sub-catchment area, one practical option is staged development from initially small-scale communal or sub-division sewerage system gradually up to the integrated sewerage system. Quezon City Separate System can adopt to this idea, where each communal sewer system will be integrated into overall system.

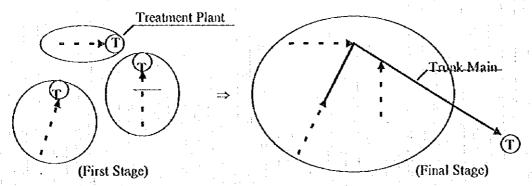

Figure 3.3.3 Staged Development of Sub-catchment Area

(3) Intercepting Capacity

One of the controversial points of a combined system is its intercepting capacity during rainy season.

The 1979 Master Plan and 1991 ADB Study proposed one x dry weather wastewater flow (DWWF) as the interceptor capacity. This is recognized as appropriate for following reasons:

- 1) There would be little advantage in increasing the interceptor capacity to reduce the extent of sanitary wastewater overflow. A study conducted by JICA in 1981 for Bangkok, Thailand showed only a 2% difference in the volume of sanitary wastewater discharged into water body between 1 x DWWF and 6 x DWWF.
- 2) Considering the weather characteristics of the Philippines, focus should be put on dry weather wastewater.
- 3) Interceptor will not be wasteful even if sub-areas will be developed by separate system.
- 4) It helps keep the construction both interceptor and treatment plant at a low cost where preliminary treatment and by-pass equipment is needed when 2 or 3 factors is adopted.

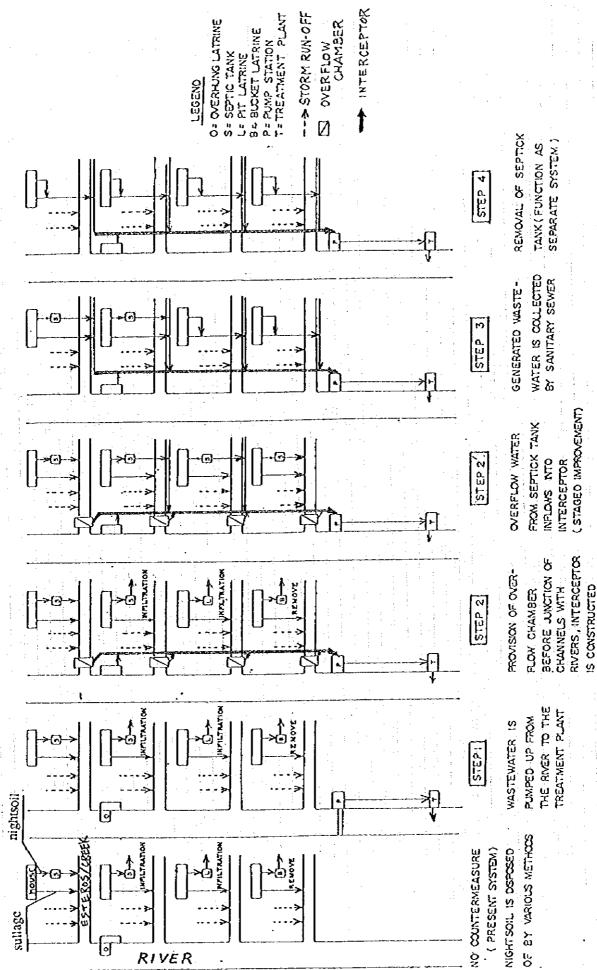

Figure 3.3.4 Staged Improvement Plan

111-38

3.2.2 Wastewater Treatment System

The existing Central Sewerage System discharges raw sewage through an outfall into Manila Bay. The proposed South Sewerage System also adopted this same method in 1991. Its theoretical background is the huge receiving capacity of Manila Bay as investigated in the 1979 Master Plan and the Bay's comparatively generous effluent standard. Manila Bay has not yet been officially classified and effluent is allowed up to 120mg of BOD (in case Manila Bay becomes a classified SC, a 100mg of BOD will be adopted).

But as reported in Manila Bay Monitoring Program in 1991, its ecological influence is not negligible. (See supporting report) Thus, the outfall system should be regarded as a temporary system.

Also from the point of recycling the water, treated water will become valuable asset.

Required conditions for the treatment method is enumerated below.

- 1 To clear effluent target level and make effluent not hazardous
- @ To be able to cope with fluctuation both in influent volume and quality
- ① Disposal of generated sludge is easy
- **©** Construction cost is low
- (9) Maintenance cost is low
- 6 Operation and Maintenance is easy

Of all the conditions mentioned, Θ is most important. As to the inland water area, effluent of treatment plant is regulated at 50mg/l of BOD in response to its being Class "C" - NPI (new/proposed industry) by DENR-EMB, while coastal areas are as before.

To prevent the degradation of Manila Bay and other river systems, a target level of <u>BOD</u> 30 mg/l which corresponds to Class "B"- NPI is hereby recommended.

No categorization by discharging point is planned.

Another constraint is space. A location that can house a huge plant is difficult to acquire in Metro Manila, so the plant sites should be efficiently utilized.

The applicable treatment methods are selected and shown below: Their design criteria is shown in supporting report.

1. Stabilization Pond (SP)

- 2. Aerated Lagoon (AL)
- 3. Oxidation Ditch (OD)
- 4. Conventional Activated Sludge (AS)

Construction and O&M costs increased from 1 to 4 and the necessary site area is the reverse. SP area needs roughly 5 times of OD (necessary site area per capacity is 1~3m²/m³), AL needs 3 times and AS needs 0.5 times of OD.

A final decision should be made looking at the conditions in its totality. A wide plant site should be acquired to cope with the future plans of expanding and upgrading the treatment levels.

As to the studge treatment, a drying bed after reducing the volume by thickening/digesting is economical as far as the site permits. Dry studge can be disposed together with solid waste or recycled for agricultural use. Excess studge is disposed of in a landfill site together with solid waste.

3.2.3 Alternative study of Sewerage System

1

In the 1979 master plan, a total of 21 alternative plans, each a combination of 27 areas (in Master Plan called "system") including the combined system, a separate system, different types of staged development, inland treatment, ocean outfall plan and others were evaluated and selected alternative plan became the 1979 Master Plan.

The first step was the review of unit sewerage zones (formerly called "system"). Basically, this zoning depends on the topographical condition considering the community boundaries, the development of the Dagat-Dagatan system, the implementation of the METROSS-I system, and also the construction of the Manggahan Floodway. Population, land use and wastewater were calculated for each zone.

The following stage was the determination of one catchment area size. Multiple small, medium and large scale collection system plans were developed and evaluated including ocean outfall with/without treatment. The evaluation was conducted under the assumption that all households in the off-site treatment area are equally served by the sewerage system.

(1) Sewerage zones

The total sewerage area of 50,692 ha (excluding the reclamation area of 1,067 ha) was divided into 27 sewerage zones mainly in compliance with the drainage basin concept, with consideration of the existing sewerage catchinent areas and community boundaries. The city/municipality vs zone matrix is shown in Table 3.3.8 and Figure 3.3.5.

(2) Alternative study of the sewerage system

The major problems are (1) the choice between proposed ocean outfall system or inland treatment, and (2) what scale is appropriate for one catchment area. This judgment highly depends on the potential site for wastewater treatment plant (WWTP) in Metro Manila where land acquisition has become more and more difficult.

Potential site for WWTP

Before proposing plans, the potential areas for WWTP were investigated from the land use map and consultant's own site survey. The required area for WWTP is assumed to be 1.5 m² per daily maximum flow in m³. After the survey, it was found that following sewerage zoning there can be a site for a WWTP only after wide re-development or if the present factories will relocate or vacate in favor of the WWTP.

North Quezon, Cubao, New Manita, Ortigas, Caloocan, Sampaloc, Guadalupe, The potential areas are shown in supporting report.

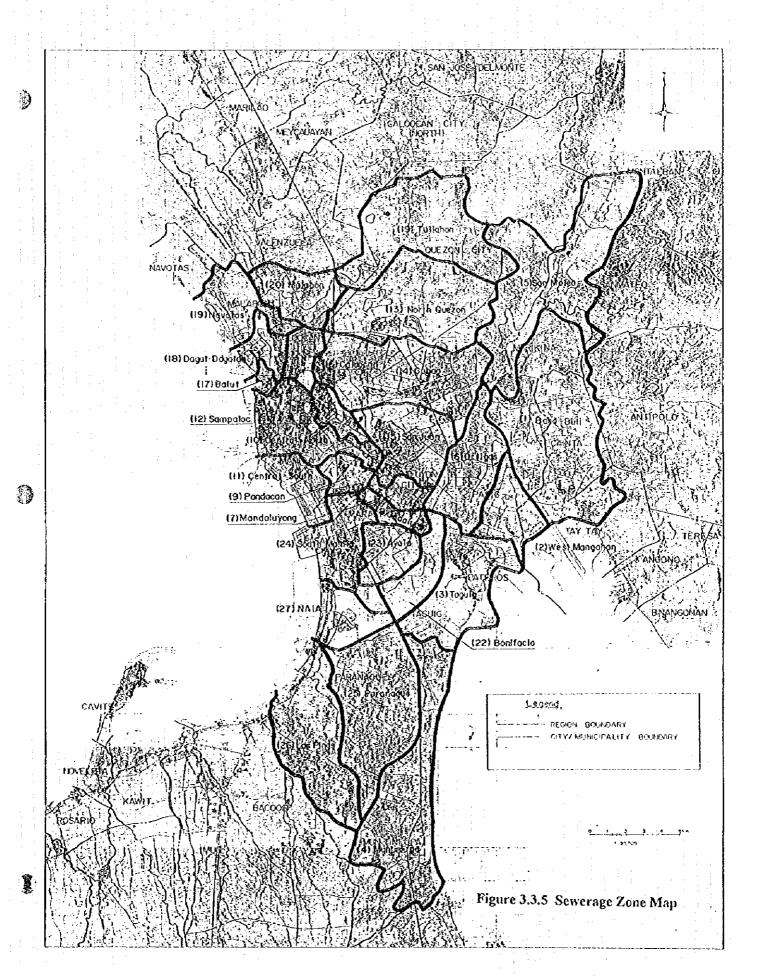

Considering the potential WWTP site, the following plans were compared. (See Figure 3.3.6)

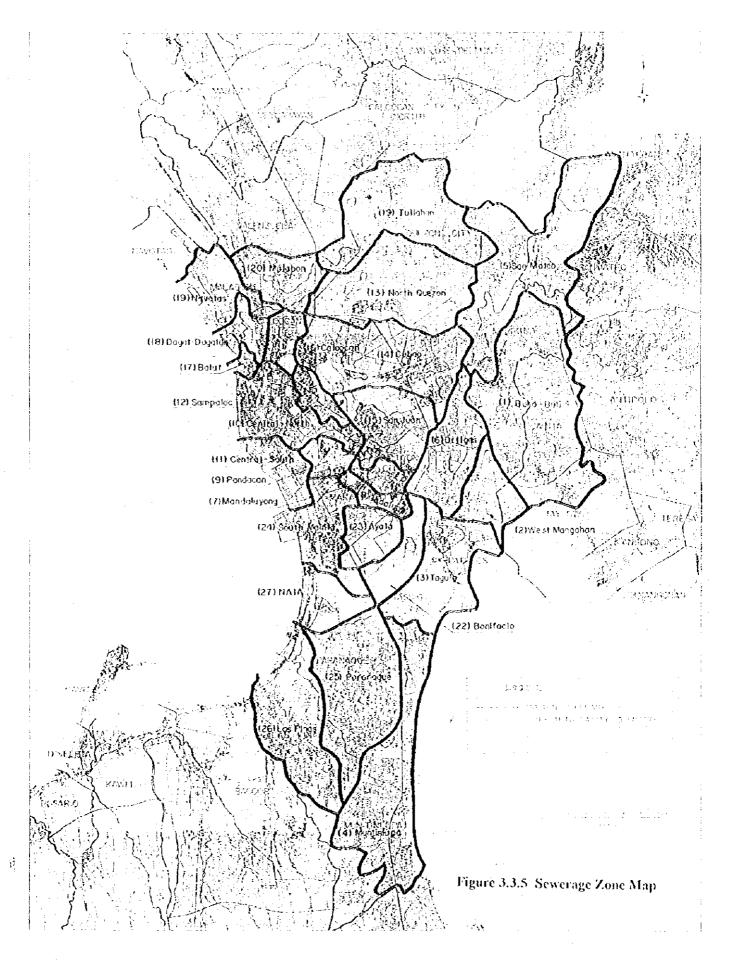

- Small Scale Inland Treatment System (SSITS)
- Medium Scale Inland treatment system(MSITS)
- Large Scale Inland treatment System (LSITS)
- Ocean Outfall System (OOS)
- Improved Ocean Outfall System(IOOS)

a. Small Scale Inland Treatment System

This system means one or a few adjacent zones have one wastewater treatment plant (WWTP) each.

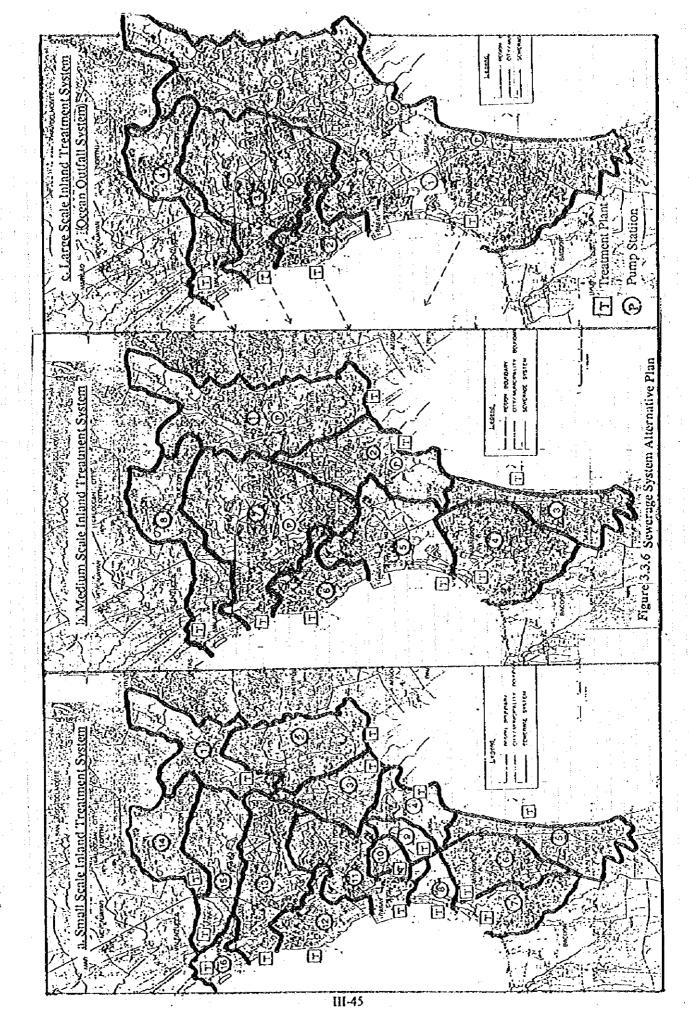

The former master plan's South System was divided into 11 catchment areas, the Central System and North System were divided into five catchment areas that cross boundary lines. The North Quezon zone was transferred to the North System considering treatment site acquisition. Wastewater is treated in the inland areas.

b. Medium Scale Inland Treatment System

Some of the small scale systems were integrated into the medium size system. The South System was divided into five areas, while the North and South System are same as in the former master plan.

c. Large Scale Inland Treatment System

Likewise, as in the former master plan, the collection method will be gathering the sewage toward Manila Bay from each river basin. Four large catchment areas (including the existing Central System) will have their own WWTP near the mouths of the NMTT, Pasig, and the Paranaque Rivers.

d. Ocean Outfall System

This system adopts same collection system of LSITS, but wastewater will be discharged through outfall into Manila Bay without treatment.

E. Improved Ocean Ontfall System

Collection system will be the same as OOS and wastewater will undergo primary treatment (sedimentation) before being discharged into Manila Bay.

The ocean outfall length may be shortened due to the wastewater's improved quality but the mechanism and receiving capacity of Manila Bay has not been clarified enough to merit shortening the outfall's length.

(3) Comparison and evaluation of each plan

a.cost comparison

A cost comparison is shown in Table 3.3.9. Land acquisition price is disregarded. A breakdown of the cost is shown in supporting report in 1993 price base. The construction cost includes the interceptor/main trunk collection system, a huge pumping station, a treatment plant, and an outfall system. To simplify the comparison, the treatment method assumed is the aerated lagoon method.

Table 3.3.9 Cost Comparison of Each System

System	Construction Cost (million Pesos)	Operation & Mai Cost (million Pes	* 1	Total Cost (million Pesos)	Remarks
		Annually	30 years		
SIIS	14,399	134	4,020	18,419	
MSITS	12,697	130	3,900	16,597	7
LSIIS	11,254	133	3,990	15,244	
oos	15,247	151	4,500	19,747	
IOOS	18,773	185	5,550	24,323	

From the above table, MSITS and LSITS look advantageous.

b.Other factors

Other factors considered are shown below.

Table 3.3.10 Comparison Table of Sewerage System

	1 able 3.3.1	0 Comparison 1	anic of Seneral	ze system

c. Recommendation

From the environmental and health points of view, the Ocean Outfall System is not recommended. Of the three inland treatment systems, the medium scale inland treatment system is the most advantageous from the other plans due to its flexibility and low initial investment cost.

(4) Optimization of the plan

Of the recommended MSITS catchment area, some additional optimization were considered taking into account the following items: the future development areas, the Dagat-Dagatan WWTP upgrading, and potential WWTP site.

O area (number is in accordance with the MSITS number in Figure 4.4): This has a narrow and long (20km) catchment area. At the early implementation of the upper Marikina river, it should be divided into two areas. It is better to draw the boundary line not according to drainage basin, but along the Marcos Highway or municipality boundary line, considering the densely populated Marikina area. A final decision should be made about the acquisition of the treatment plant area. The wastewater in the Marikina municipal area in the Bali-Buho sewerage zone will be converted into the San Mateo sewerage zone.

Area	1,306 ha
Pop.	295,576 persons
Wastewater(daily max)	72,055 m3/d

© area: This can be divided into a catchment area with the existing Ayala System and the future development plan to initially save on cost. The Ayala System can stay for the time being until after the MSSP rehabilitation. Large scale developments like the Fort Bonifacio and Villamor Air Base areas should have an independent sewerage system with the cost to be shouldered by the developer. NAIA has its own treatment facility and its wastewater should be exempted from the lower area planning.

6 and 2 area

Three plans were considered and compared. Alternative figure is shown in Figure (Case 1)

Treatment plant site will be secured in San Juan river basin by transfer/removal of built-up area. The Tondo pump station will deliver its sewage to Dagat-Dagatan WWTP, which will be upgraded to a secondary treatment plant for the Central System and its expansion area as proposed in MSSP.

(Case 2)

Treatment plant site for San Iuan river basin will be secured in the Malabon-Navotas area together with the North System. The Tondo Pump Station will deliver its sewage to the Dagat-Dagatan WWTP, which will be upgraded to a secondary treatment plant for the Central System and its expansion area as proposed in the MSSP.

Two alternatives of Case 2 can be considered; (1) Case 2(a); A treatment plant site is acquired in the Laguna Lake shore area adjacent to the West Mangahan treatment plant site and (2) Case 2(b); A treatment plant site is secured in the Manila Bay Reclamation Area next to the South Manila System treatment plant. Case 2(a) is cheaper than case 2 because force main can be

shortened but its plan transfer 6.0 m3/s of wastewater to the upper stream of Pasig River. Its hydrological effects hinders the adoption of this plan. Case 2(b) requires significant land reclamation and its probability is very small.

(case 3)

A new treatment plant for Central System will be constructed in a reclaimed area in Manila Bay near the Tondo pump station. The Dagat-Dagatan WWTP will be developed for the San Juan river basin area.

To make efficient use of the limited land, Dagat-Dagatan WWTP area should be utilized to the fullest. About 16 ha (including future Module 3 area now occupied by squatters) can provide about 500,000 m³/d of treatment capacity using activated sludge method.

From the probability of land acquisition, case 2 is recommended.

Table 3.3.11 Comparison of Optimization Plan

	table 3.3.11 Compariso	17 01 (5) 5011111111111111111111111111111111111	
	Case 1	Case 2	case 3
Construction cost	174million	4626million	<u>5406 million</u>
	pesos	<u>pesos</u>	<u>pesos</u>
Land Acquisition	confluence of San Juan and	Marine pond area is easier to secure than other place	Reclamation off the Tondo Pump Station is difficult
	Pasig is difficult		

Breakdown is shown insupporting report.

Optimized plan is shown in Figure 3.3.8.

Outline of each catchment area is shown in Table 3.3.12. North Manila is divided into two sub-catchment areas.

Marikina system

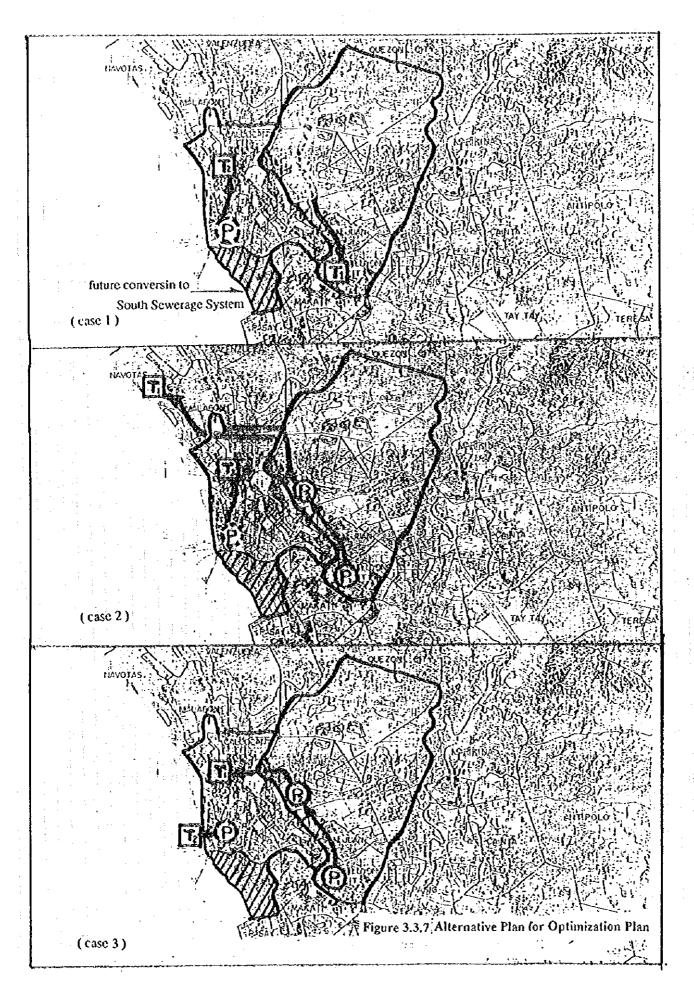

The interceptor/Main trunk is installed along J P Rizal road and treatment plant is situated near the Marikina river. Due to site constraint, the oxidation ditch method is considered.

East Mangahan

The main trunk is along Imelda Avenue and treatment plant will be constructed in the rice field near the confluence of the Baho River and Manggahan flood way. The treatment method is an aerated lagoon method.

West Mangahan

The main trunk comes from the Ortigas area passing the Marikina River through Pasig to the boundary area of Pasig/Cainta/Yaguig where an aerated lagoon plant will be built.

Muntinlupa

Reclamation area in Laguna Lake has to be efficiently used and activated sludge, which needs least area, is as the considered treatment method

Paranaque

The trunk main is installed to intercept wastewater running from the highland to Manila Bay. The treatment plant is located in the low land now being used for a marine pond. An aerated lagoon is considered.

South Manila

Tthe treatment plant will be constructed either in the reclamation areas or the marine pond area considering the land cost and possibility of acquisition. Staged development is studied in this area because this area includes future conversion area where is now temporarily connected to
