#### a. Method applied

#### aa. Indicators for the forecast of future ISW generation

Based on the estimated amount of present ISW generation, a forecast of future ISW generation in 2010 was conducted by applying the Standard Unit Method (SUM) which required the estimation of the following indicators.

#### aaa. Population figure for the forecast: Number of Employees

Concerning the population figure for forecasting ISW generation, there are three major indicators, i.e. annual production, annual sales of products, and the number of employees. Since the data available to be required for the forecast is very limited regarding yearly production and annual sales, the number of employees was used as the population for the forecast. However, industrial production will increase by the modernization of production system etc. even though there is no increase in number of employees. Therefore, annual production or annual sales of products should be used as the population figure for forecasting ISW generation when such data is available in the future. The details of the method and result of the forecast is described in the previous section ; i.e. forecast of future socio-economic conditions.

#### aab. Generation ratio

Ĩ

The generation ratio of ISW fluctuates in accordance with various factors. In the Study, the following two factors were examined for the forecast of future ISW generation.

i. Variation with the introduction of cleaner production technology (CPT).
ii. Difference with the installation rate of the following pollution control facilities (PCF):

- Water pollution control facility:

Installation rate (SISS) and sewage treatment plan (EMOS) Installation rate (PROCEFF)

Air pollution control facility:

#### ab. Variation factors of ISW generation ratio

#### aba. Variation of ISW generation ratio with the introduction of Cleaner Production Technology (CPT)

To estimate the fluctuation of unit ISW generation by introducing CPT, a more detailed factory survey is needed to identify the representative production system for each of the 36 or more specific sub-sector of the manufacturing industry. Based on such survey, it may be possible to assume variation rate by CPT introduction. However, due to the time limit and availability of statistics and information, it was impossible to estimate the variation rate. Instead, as mentioned above, the Study assumed and incorporated the labor productivity factor in the forecast of the future number of employees. Since many of the CPT were developed at a time of increasing productivity, during the period of high economic growth in Japan, the factor of minimizing unit ISW generation by CPT introduction is somehow automatically incorporated in the process of forecasting the number of employees.

#### abb. Variation rate by installation of PCF

The installation rates of pollution control facilities (PCF) for air and water pollution were determined as the target of the Master Plan respectively as shown in Table I.2.2a below.

Table I.2.2a	Installation Rate of Pollution Control Facilities
--------------	---------------------------------------------------

Year	Installati	on Rate (%)	
Types of PCF	Unit	1995	2010
Air PCF	Installation Rate (%)	48.9 <sup>*1</sup>	100
On-site Water PCF	Installation Rate (%)	2.1*2	100
Public Sewage Treatment	Installation Rate (%)	2.0	100

Note:

\*1: Percentage of gas effluent quantity through the "filter" over total gas effluent quantity in the MR (source: SESMA-PROCEFF data)

\*2: Source; information of SISS, MOP

#### ac. Transition of Dust and Sludge Generation Rate

It is estimated that, at present, 51.1% of "Dust and APC (Air Pollution Control) Products" and 98% of "Sludge" are discharged into the air and public water course without any treatment. Whereas, it is assumed that 100% of waste water and gas effluent shall be treated by the year 2010; quantities of dust and sludge as ISW are estimated in the next section.

#### ad. Forecast

The forecast of ISW generation in 2010 was based principally upon data obtained from the Team's factory survey and EWI's RISNOR study except for sludge and dust. Hence, the ISW generation in the year 2010 is the product of "generation rate in 1995" and "forecasted employee number in 2010" for 36 respective industries' classification. The forecast of sludge and dust generation, on the other hand, is conducted by the respective methods described below.

#### b. Forecast of sludge generation

#### ba. Outline

1

Generally, sources of sludge generation in factories are:

- on-site waste water treatment facilities, and
- manufacturing processes of products.

Meanwhile, it was found, as the result of factory survey, that:

- Most of factories do not posses waste water treatment facilities, and
- Sludge generated from manufacturing processes, which shows a high water content and/or is unsuitable for reutilization in the factory, is discharged directly into the sewers.

Whereas, the present state of sewerage system in the MR is that:

The sewer network is substantially completed, and

Sewage treatment facilities are still under preparation and only about 2% of sewage in the MR is currently subject to treatment.

Since the sewer system in the MR is substantially completed, the rate of sewage treatment in the MR will be drastically improved as the treatment plants commence their operation. Consequently, a huge amount of sludge will be generated in future. The national norm (i.e. Nch2280) stipulates maximum limits for industrial liquid waste to be discharged into the public sewerage system (refer to Table I.2.2b), the newly

built factories should bear this in mind if they need to discharge their industrial waste water into sewage line.

Sewei Li		
Item	unit	Maximum Limit
рН	<b>-</b>	5.5 to 9.0
Temperature	°C	<35
Suspended Solid	mg/l	300

Trichloromethane	mg/l	<b>0.5</b>
Phenolic Compounds	mg/l	0.5

Table I.2.2bMaximum Limits for Industrial Liquid Waste Water Discharge into<br/>Sewer Line

In this context, sludge attributable to waste water treatment are:

- sludge generated from on-site waste water treatment facilities (to comply with the maximum limits of Nch2280), and

£

sludge generated from public waste water (contaminated with discharged industrial waste water with permissible limits) treatment facilities.

2.5

. . . .

Hence the sludge generation amount is forecasted based on the above two factors.

#### bb. Sludge generated from on-site waste water treatment facilities

Since regulations of Nch2280 are not imposed on the majority of factories to date, sludge generation rates obtained through the Team's factory survey are a conservative estimate. In future, due to enforcement of Nch2280 regulations (i.e. the regulations will also be imposed to existing factories), the increase in sludge generation will be overwhelming.

Therefore, if a similar method, as applied in the forecast of other ISW generation in future (i.e. forecast based on increase of employees), is employed for the forecast of sludge generation in future, the estimated amount should be definitely undervalued.

In this context, since factories' waste water quantities in proportion to the amount of water they consume and waste water quality surveyed on individual industries (e.g. waste water quality for CIIU 3111: BOD 810 mg/l, SS 460 mg/l) was not available, the forecast was carried out by applying the methods below:

i. Firstly, "waste water rate (per employee) defined here as  $\underline{\alpha}$ ", which is proportional to "water-consumption rates (per employee)", of individual industries in the MR are calculated based on the Team's investigation. Although Japanese empirical data of "rationalization in water consumption" is not included in the calculation, a table for change of water-consumption rates between 1973 to 1984 per employee for individual industries in Japan is prepared for a reference material (see Table I.2.2c).

I.

- ii. Secondly, waste water (biochemical oxygen demand and suspended solid; hereafter BOD and SS respectively) concentration of respective groupwise industries in the MR are set out with reference to the data in Japan obtained through a survey done by the Ministry of Construction in Japan. (refer to Table I.2.2d)
- iii. Thirdly, "waste water BOD/SS concentration obtained from ii. above" minus "maximum limits of BOD/SS concentration defined in Nch2280" give respective BOD/SS concentration to be removed on-site (hereinafter defined Br and Sr).
- In calculation of sludge amount to be generated in factories through onsite BOD/SS removal processes;

 Sludge generated from "oxidative decomposition process of BOD" (hereinafter Bg); and

Sludge generated from SS removal process (hereinafter Sg)

should be considered. Generation ratio per employee (hereinafter Tg) is calculated as:

$$Tg = Bg + Sg$$

Bg and Sg are calculated based on following assumptions.

v. Bg is calculated by the following formula with an assumption that : BOD to be removed will be (oxidatively) decomposed 50% into carbon dioxide (CO<sub>2</sub>) and 50% into sludge.

 $Bg = \alpha \times Br \times 0.5$ 

vi. Sg is calculated by the following formula with an assumption that all SS removed is transformed into sludge.

 $Sg = \alpha \times Sr$ 

vii. The sludge generated from the removal of dissolved inorganic substances through physical-chemical treatment is not projected in the estimation due to lack of available data for whole industries (available for some industries).

Accordingly, the sludge generation rates per employee are the values of on-site sludge (dry content) generation, assuming that all factories comply with the Nch2280 regulations in their on-site waste water treatment.

Accordingly, future sludge generation amount (dry content) is estimated from:

"Tg" above multiplied by estimated future employee numbers

Where sludge generation amount obtained from the above comprises:

i. amount of inorganic sludge (dry content), and

ii. amount of organic sludge (dry content).

The factory survey gives the estimated proportion of 'inorganic sludge" and "organic sludge" to being 32% and 68% respectively.

Meanwhile, water content of "inorganic sludge" and "organic sludge" are estimated 90% and 99% respectively with reference to visual observations at the factory survey

and to Japanese empirical data. The water content in the sludges should be reduced for the purpose of the transportation. It can be reached to a water content of 85% (i.e. the minimum requirement for transportation through a mechanical treatment. It can be reduced to lower than 85% through drying systems.

The sludge generation amount in 2010 based on the above assumptions is calculated, as shown in Tables I.2.2e and I.2.2f.

#### bc. Sludge generated from public sewage treatment plants

#### bca. Outline of public sewage treatment plan

EMOS has a long term programme of sewage treatment diffusion (in terms of rate of population served) as shown in the Table below.

Year	1992	1995	1999	2004	2009	2024
Sewage Treatment	0%	2.0%	25.0%	27.5%	100%	100%
Plan						

 Table I.2.2g
 Sewage Treatment Plan in Greater Santiago

Source: EMOS

The amount of total suspended solid to be received in sewage treatment facilities are estimated as follows (refer to Table below).

 Table I.2.2h
 Mass of Inlet Suspended Solid to Sewage Treatment Plants

Unit: kg/day

Year	1992	1995	1999	2004	2009	2024
Inlet Suspended Solid	0			113,183	607,552	
(dry content)						

Source: EMOS

्रि

It is planned that 95% of suspended solid received shall be removed. The sludge treatment processes proposed for the programme are:

"Studge Thickening" + "Digestion" + "Dehydration".

Meanwhile, it is planned that water content after dehydration shall be 75%.

Sludge generated after the processes are expected to be disposed at landfills. Although candidate locations of landfills are expressed in the plan, no specific action for localization of disposal site is underway.

In relation to the sewage treatment programme outlined above, amount of sludge generated from public sewage treatment plants to be disposed is calculated.

#### bcb. Estimation of sludge to be disposed

#### i. Assumptions

The estimation of sludge amount is based on the assumptions expressed below.

•

All suspended solid removed by the sewage treatment plants converted to sludge.

- Empirical data obtained at the Santiago Poniente Plant of EMOS (Planta de Tratamiento de Agua Servidas Santiago Poniente) suggest the proportion of "inorganic matter" and "organic matter", in treated sludge, to be 50% each.
- According to the empirical data in Japan, 50% of organic matter in sludge is decomposed to water and methane gas by sludge digestion.
  - The water content of dehydrated sludge cake is 75% as mentioned in the EMOS's plan.

#### ii. Outcome of the estimation

The outcome of the estimation based on the assumptions above are shown in the table below.

Ycar	1992	1995	1999	2004	2009	2024
Inlet suspended solid (DS kg/day)	0	6,142	92,220	113,183	607,552	607,552
Removed SS at sewage treatment plants (DS kg/day)	0	5,835	87,609	107,524	577,174	577,174
SS after digestion (DS kg/day)	0	4,376	65,707	80,643	432,881	432,881
Dehydrated cake (moisture content 75%, m <sup>3</sup> /day=ton/day)	0	17.5	262,8	322.6	1,731.5	1,731.5
Final disposal amount (moisture content 75%, ton/year)	0	6,388	95,922	117,749	631,998	631,998

bd. Conclusions

Table below shows "Forecast for Total Sludge Generation Amount" as a summary of the above estimation.

Sludge Generation Source	Туре	Moisture content	1995 (ton/year)	2010 (ton/year)
Factories	In-organic	90%	47,035	309,879
	Organic	99%	43,518	6,585,469
Sewage Treatment Plants	Organic	75%	6,388	631,998
	In-organic	· •	47,035	309,879
Total	Organic	-	49,906	7,217,467
	Total	-	96,941	7,527,346

 Table I.2.2j
 Forecast for Total Sludge Generation Amount

#### c. Forecast of dust generation in 2010

(I)

×.

Dust generation rations obtained by the factory survey amount to less than half of categories of industries as shown in Table I.2.2k. Forecasted amount of dust generation in 2010 shall be a conservative estimate if the forecast is conducted without generation ratios for industries which are unaccounted for at present. In order to get the generation ratios of several industries for which ratios were not obtained by the Team's survey, generation ratios surveyed in Japan by the Ministry of International Trade and Industry (MITI) were examined and tabulated in Table I.2.2l.

However, as clearly understood by the table, there are large differences between the ratios obtained by the Team's survey and MITI. In addition, it is hard to get correlation of them. This is due to differences of production processes, raw materials, fuels, flue gas treatment facilities, emission standards, etc.. Thus generation ratios of similar categories of industries, which were obtained by the Team's survey, are applied to dust generation in 2010.

On the other hand, the installation rate of facilities emitting exhaust fumes is 82% according to the Team's Factory Survey (although the SESMA-PROCEFF data base has the installation rate in the MR, it does not provide the rate in accordance with the CIIU code). Consequently, dust generation amount in 2010 is presented in Table 1.2.2m.

I-78

This section outlines the present and the future generation of Medical Solid Waste. Basic prerequisites for this work are classification of Medical SW, hereunder identification of potentially infectious waste types and identification of the potential producers of Medical SW. In terms of Medical SWM, the quantity of infectious waste types is the main basic data to be investigated as infectious waste types require special attention and a separate handling system.

Radioactive waste is another waste type requiring special attention, however, radioactive waste is not included in the scope of work of the Study.

The quantity of chemicals and other general hazardous waste types generated in the medical institutions is rather small compared to the generation in the industrial sector. Thus, chemicals and other general hazardous waste types generated in the medical institutions should be included in the management system proposed for industries etc.

In relation to the determination of the quantity of infectious waste it is deemed important briefly to discuss the actual and perceived risks connected to handling of Medical SW.

#### I.3.1 Classification of Medical Solid Waste

T

X

Medical (solid) waste is defined as follows in the context of the present Master Plan study:

(Solid) waste generated in the diagnosis, treatment or immunization of human beings or animals, in related research, or in the production or testing of biological agents.

Solid is put in a clause as in terms of medical waste, a number of liquid waste types such as biological agents and blood are regarded infectious and, thus, being included in the same handling system as solid waste types. Thus, there is not the same distinction between solid and liquid waste as known in Municipal Waste.

There are several classification systems for medical SW. They all originates in the philosophy that a part of the waste being similar to municipal solid waste (and may be collected and treated as such) and a part being either of infectious (and unaesthetic) nature or general hazardous wastes.

The following waste classification system for medical SW is proposed (see table I.3.1a at next page for the detailed definition). The proposal combines the classification recommended by WHO and definition of waste types applied by US-EPA:

- Pathological waste ,
- Human blood and blood products ,
- Cultures and stocks \*,
- Sharps ,
- Infectious waste \*,
- Animal waste,
- Chemical waste,
- Radioactive waste,
- General (non-hazardous) waste.

The waste types marked with an asterisk are potentially infectious types.

#### a. Producers of Medical Solid Waste

Hospitals and clinics are the main generator of medical SW, but also some minor sources should be considered in the long term development of the medical SW management system.

Table I.3. 1b presents a list of sources of medical SW grouped according to the likely size of waste generation. The list is representative rather than the precise picture in Santiago. It should be added that even very developed medical SW systems may not include all the listed small size producers as the collection system will be relatively costly.

	I I I I I I I I I I I I I I I I I I I
Waste type	Description
Pathological waste	Tissues, organs, body parts, human fetuses and other human parts (recognizable and unrecognizable).
Human blood and blood products	Liquid human blood and products of blood; items saturated with human blood (including caked blood); including serum, plasma and other blood components and their containers.
Cultures and stocks	Cultures and stocks of infectious agents and associated biologicals, including cultures from medical and pathological laboratories; cultures and stocks of in- fectious agents from research and industrial laboratories; waste from the pro- duction of biologicals; discarded live and attenuated vaccines; and culture dishes and devices used to transfer, inoculate, and mix cultures.
Sharps	Sharps that have been used in animal or human patient care or treatment or in medical research, or industrial laboratories, including hypodermic needles, syringes, Pasteur pipettes, scalpel blades, blood vials, needles with attached tub- ing, and culture dishes (regardless of presence of infectious agents). Broken or unbroken glassware that were in contact with infectious agents, such as used slides and coverslips.
	Hypodermio needles, suture needles, syringes, scalpel blades and other unused, but discarded sharp items.
Infectious waste	Biological waste and discarded materials contaminated with blood, excrement, exudates, or secretion from humans who are isolated to protect others from cer- tainly highly communicable discases, or isolated animals known to be infected with highly communicable diseases.
Animal waste	Contaminated animal carcasses, body parts, and bedding of animals known to have been exposed to infectious agents during clinical trials.
Chemical waste	Discarded solid, liquid and gaseous chemicals, for example from diagnostic and experimental works, disinfecting procedures, preservation purposes, and cleaning. Hazardous chemicals includes waste that is toxic, corrosive, flammable, reactive and cytotoxic.
Radiosctive waste	Includes solid, liquid and gaseous waste contaminated with radio nuclides generated from analysis of body tissues and fluids, body organ imaging and tumor tocalization, and therapeutic procedures.
General non-hazardous waste	Domestic-type waste, including packaging materials, kitchen waste, non- infectious waste from wards and other substances that do not pose a special handling problem or hazard to human health or the environment.

0

There is widespread concern over the safe management and disposal of medical SW due to its possible hazardous or infectious contents.

The risks arising from handling, treatment and disposal of medical SW may be placed into two categories; the medical (real) risk recognized by health professionals and the risk perceived by the public.

#### The Real Risk

(I

There are in principle 4 ways for transmission of pathogenic micro organisms (bacteria, virus, fungi and parasites):

- 1: Through the skin; via lacerated skin or penetration by needle or other sharp or pointed object.
- 2: Through the surface of mucous membranes.
- 3: Through the respiratory passages via inhalation.
- 4: Through the gastrointestinal canal by consumption of infectious material.

The risk of transmission of pathogenic micro-organisms (in medical term) from medical SW is virtually considered at the same level as of municipal SW which is considered minimal. The particular concern is related to Hepatitis B and human immunodeficiency virus (HIV). These virus are primarily transmitted through the contact of body fluids and, thus, the risk of infection is closely associated with blood contaminated sharp objects such as needles and splintered bones.

Thus, provided sharps and pointed items are properly packed, the main risk arises during the generation of the waste. Through careful source separation and use of unbreakable packaging, the risk of infection during the subsequent waste handling is minimal. In fact, medical literature do not report on any case where a person has contracted an infection from medical waste except in case of a physical injury of the skin caused by sharp objects.

#### The Risk Perceived by the Public

In general, the public exaggerate the risks posed by medical SW. The rare incidents

involving medical SW have been disproportionately highlighted and much publicized by the media (HIV accidents with sharps, illegal dumping of medical SW, etc.). Thus, it is natural that the public perception of risk varies distinctly from the professional medical view.

Although it may be inappropriate to respond on the perceived risk (as this is not real), the public perception must be observed in the medical SWM system. Thus, it is adequate to require medical SW being kept in a *separate handling system* with proper treatment and disposal facilities for infectious waste types.

Finally, the public responds on the risk of being confronted with recognizable, unpleasant waste items such as human limbs, placentas, syringes etc.

Confrontation with these medical waste types may not constitute a particular risk of transfer of disease etc. However, it will certainly affect the person and provoke disgust and anger. This, what we may describe as an aesthetic based conflict, should be given considerable attention in choice of the handling system.

#### I.3.2 The Present Generation of Medical Solid Waste and the Waste Flow

#### a. The Present Generation of Medical Solid Waste

The registered waste generation is generally higher in ADIMARK's RESHOS Study than that observed by EWI's RESHOS Study. This is probably due to the survey methods and due to the fact that the ADIMARK Study includes all waste types, e.g. also liquid waste. Table I.3.2a presents waste generation data obtained from the two studies.

 Table I.3.2a
 Waste Generation Data According to Studies Conducted by EWI and ADIMARK

Note:

1} 2)

1

Average for public (4 types) and private hospitals.

EWI category risk waste exclusive of pathological waste.

3) Based on limited samples.

4) The generation ratio in this table is the survey results before the adjustment of 25% reduction.

Table I.3.2b compares waste generation data for various countries. It appears that data obtained by ADIMARK correspond to the international trend, however, somewhat in the higher end of the selected countries. The likely lesser use of disposable equipment in Chile compared to some other countries makes it reasonable not to expect the medical SW generation today to be in the high end. For the subsequent planning we propose to apply a 25% reduction of the figures obtained by Adimark. In Table 3.2c the total medical SW generation estimate for the Metropolitan Region of Santiago.

Place	Total generation of medical waste	Generation of waste of infectious nature
Santlago, Chile <sup>1)</sup>	1.9187 kg/bed/day = 1.82 kg/capita/year (EWI)	0.6561 kg/bed/day = 0.62 kg/capita/year (EWI)
	5.3235 kg/bed/day = 5.04 kg/capita/year (ADIMARK)	1.6598 kg/bed/day = 1.57 kg/capita/year (ADIMARK)
Latin America <sup>2)</sup>	3 kg/bed/day	20% of 3 kg =0.60 kg/bed/day
Belgium	11 kg/capita/year	1.4 kg/capita/year
Denmark		1.95 kg/capita/year 1.3 kg/bed/day
France	12.8 kg/capita/year	1.9 kg/capita/year
Germany	1.15 kg/capita/year	0.4 kg/capita/year
Ireland	6.1 kg/capita/year	2.6 kg/capita/year
Italy	2.6 kg/capita/year	1.0 kg/capita/year
Mexico City	2.4 kg/capita/year 4.73-5.38 kg/bed/day	0.24 kg/capita/year
Netherlands	10.8 kg/capita/year 2.3-6.5 kg/bed/day	0.6 kg/capita/year
Portugal	4.9 kg/capita/year	1.5 kg/capita/year
Spain	4.9 kg/capita/year 4-4.5 kg/bed/day	0.6 kg/capita/year 0.4-0.5 kg/bed/day
United Kingdom	5.5 kg/capita/year 2.5-3.3 kg/bed/day	5.5 kg/capita/year
USA	4.1-5.24 kg/bed/day	

 Table 1.3.2b
 Generation of Medical Waste in Various Countries

Note: 1) The conversion from generation per bed to generation per capita is based on all 14,517 beds at hospitals and clinics and 5.6 millions inhabitants. Medical SW from other sources is not included.

2) Average assumed generation for Latin America according to Organizacion Panamericana de la Salud and Organización Mundial de la Salud (INK3/).

3) Sources: /NK1/, /NK2/, /NK3/ and research made by RH&H Consult in Mexico City.

The Present Medical Solid Waste Generation, Santiago Metropolitan Region 1995 Table I.3.2c

Ŷ

1

Source					
	Units	Total waste generation per unit	Annual total waste generation	Generation of infectious waste types per unit	Annual generation of infectious waste types
Hospitals	12,938 beds	0.75 • 5.32 = 3.99 kg/bed/day	18,800 tons	0.75 • 1.66 = 1.25 kg/bed/day	5,900 tons
Clinics	1,579 bods	0.75 + 5.84 = 4.38 kg/bod/day	2,500 tons	0.75 • 2.06 = 1.55 kg/bed/day	900 tons
Sub-total for hospitals and clinics		<b>f</b>	21,300 tons		6,800 tons
Rural health centers and rural/urban surgerics	164 units	15 kg/unit/day	900 to <u>n</u> s	Approximately 20%	200 tons
Other sources			1,400 tons	Assumed 20%	300 tons
TOTAL	I		23,600 tons	ſ	7.300 tons

There is a disparity between the composition of special medical SW from hospitals and clinics in the two studies as seen from Table I.3.2d below.

Table I.3.2d	Composition of Medical Solid Waste from Hospitals and Clinics
	According to Studies (Infectious Types only)

Waste type	EWI	ADIMARK
Pathological waste	9.5%	18.8%
Cultures/stocks and blood products	1.0%	23.2%
Sharps	4.8%	18.8%
(Other) infectious waste "	<u>ñ.a.</u>	39.2%
Surgical waste (dressing etc.)	76.1%	n.a.
Waste from isolation wards	8.6%	<u>13.8.</u>

Note: 1) Here, the term infectious waste should not be compared or mixed up with the term used in the classification.

EWI's study is the most reliable with respect to the waste composition as actual sorting and weighing were carried out. However, the percentage of cultures/stocks is underestimated in EWI's study, probably because of its contents of liquid waste, which to a large extent is disposed of in the sewer. In order to estimate the present waste flow, the composition in Table I.3.2e below is assumed for infectious types of medical SW from hospitals and clinics. This assumption is the *best estimate* assessed by the JICA Study Team.

Table I.3.2e	Assumed Composition of Medical Solid Waste from Hospitals and
	Clinics (Infectious Types only)

Waste type	Composition	Quantity
Pathological waste	10%	680 tonne
Cultures/stocks and blood products	15%	1,020 tonne
Sharps	5%	340 tonne
Infectious waste	70%	4,760 tonne
TOTAL (hospitals and clinks)	100%	6,800 tonne

#### b. The Waste Flow

Table 1.3.2f presents the assumed flow of waste of infectious nature from hospitals and clinics.

The Present Waste Flow for Medical Solid Waste from Hospitals and Clinics (Infectious Types only) Table I.3.2f

Pathological	680	34	230	35	240		20	13	8	3	20	12	80
Cultures/stocks and blood products	1,020	3	30	53	225	80	80	34	345	17	175	16	165
Sharps	340	s.	20	58	95	18	60	34	115	0	0	21	ŝ
Infectious waste	4,760	S	5 240	32	1,525	22	1.045	19	905	8	380	14	<b>665</b>
TOTAL	6.800 v	90	\$20	E	2.085	18	1.455	1	1,455	90	575	14	80

Note:

Note that only infectious type wartes from hospitals and clinics are included (6,300 tones in 1995 versus the total extimate of 7,300 tones). ନ ନ ନ

Distribution on disposal methods is according to ADIMARK's RESEAOS Study. The indicated flow is the primary waste flow. Waste sterilized by autoclave will afterwards be disposed of by incineration, landfilling and via the sewer.

#### I.3.3 Forecast of Medical Solid Waste Generation

The forecast of medical SW generation for the period 1995 - 2010 is developed for waste of infectious nature, i.e. the first 6 categories of the classification in section I.3.1.

赣

#### a. Forecast Method

The generation of waste of infectious nature depends on a number of factors such as the population, the general hygiene standard applied in society and at medical institutions, the development of preventative medicine and development of curative methods.

A number of the above-mentioned factors are not statistically quantifiable and, furthermore, they are uncertain in respect of the possible impact on the medical SW generation. Thus, for the Master Plan Study it is proposed to forecast the future medical SW generation based on the development of the population combined with an assumption of the possible impact of developed welfare of the individuals and the society.

The generation of medical SW is assumed to develop linear to the development of population of society. Increased welfare is likely to improve hospital hygiene, which normally means increased use of disposable equipment and, consequently, increased waste production. However, modern hospital SW management includes attention to possible methods for reduction of the waste quantities, e.g. through resource minded and environmental conscious purchasing of equipment and consumables.

There are no available historical information for quantification of the possible impact of the above-mentioned factors. For this study, an annual increase of 1% is assumed.

#### b. Forecast

Table I.3.3a shows the population projection 1995-2010 for the Santiago Metropolitan Region and the projection of medical SW generation (infectious waste types only).

e anna 1977				
Year	Projection of	population	Effect of improved hospital hygiene	Projected generation of medical solid waste
	Total	Index	noobrat nygrar	of infectious nature (tors)
1995	5,642,000	100.00	100.00	7,300
1996	5,738,000	101.70	101.00	7,500
1997	5,831,000	103.35	102.01	7,700
1998	5,923,000	104.98	103.03	7,900
1999	6,013,000	106.58	104.06	8,100
2000	6,102,000	108.15	105.10	8,300
2001	6,190,000	109.71	106.15	8,500
2002	6,276,000	111.24	107.21	8,700
2003	6,361,000	112.74	108.29	8,900
2004	6,445,000	114.23	109.37	9,100
2005	6,528,000	115.70	110.46	9,300
2006	6,610,000	117.16	111.57	9,500
2007	6,690,000	118.57	112.68	9,800
2008	6,770,000	119.99	113.81	10,000
2009	6,850,000	121.41	114.95	10,200
2010	6,931,000	122.85	\$16.10	10,400

# ANNEX J INVESTIGATION AND INITIAL ENVIRONMENTAL EVALUATION OF CANDIDATE SITES FOR HAZARDOUS WASTE DISPOSAL

# J.1 Suggested Guidelines for Selection of Potential Areas for Major Facilities for Industrial Solid Waste Management

#### J.1.1 Introduction

Included in the Study is an agreement that criteria for selection of option areas for treatment/disposal facilities shall be set up in the beginning of the study. Based on these criteria the Chilean authorities will select option areas (candidate sites) to be assessed by the Study Team in the next phase of the project in July-August 1995.

This annex contains the suggestion for the selection criteria to be applied as provided by the Study Team at the end of the first work period in Chile in February-March 1995.

### J.1.2 Site Selection Method

1

It is generally assumed that the selection of the most proper sites for waste treatment and disposal (in this case one or more waste treatment plant(s) and landfill(s)) should take part applying a negative selection method because it is generally assumed that it is difficult to make most people think of such an enterprise in as a positive thing. The stages suggested are as follows:

a. Identification of potential localization areas and sites

b. Selection of candidate sites

c. Assessment of candidate sites

In the first stage (a) the areas most suited for the localization of a site will be identified by a preliminary investigation excluding those areas where it is for different reasons not commendable to establish a site. From these options the most evident among the areas identified as reasonable options are selected as candidate sites (b). For these ones a final investigation and recommendation will take place in the third phase (c).

It is assumed that 3-4 candidate sites should be selected for treatment plants and

landfills, respectively.

Of these issues, the Chilean side will conduct phase a and b based on the suggested selection criteria and other relevant national legislation, regulations, guidelines etc. At least an abstract of these criteria documents must be made available to the Study Team for the final assessment (c). Other relevant documents such as maps applied in the first phases and other issues as described in section J.1.3a below must be made available as well.

The considerations made by the Chilean authorities must also be made available to the Study Team for each of the selected candidate sites. These will be basic documents for further assessment and must therefore be available in English.

### J.1.3 Conditions to be Considered for Selection of Potential Sites

The key factors to be considered in the selection of potential sites are:

- 1. Possibility of land acquisition
- 2. Compatibility with national or regional development plans
- 3. Environmental acceptability
- 4. Economic feasibility

It is assumed that 1. and 2. above will play a major role in the first stages of the project (a. and b. in section J.1.2 above), whereas 3. and 4. will be the major issues in stage c., because the relations to 1. and 2. have been clarified in the first to stages. However, the whole study basis must be established before the resumption of this part of the study by the Study Team in July 1995.

The reaction of potential neighbours should also be considered, but as it generally understood that Chilean legislation does not require neighbourhood consensus if only certain requirements of distance to the sites are fulfilled (600 metres from populated areas, 300 metres from single dwellings). This as therefore not considered a major issue if only it is assured that these requirements are fulfilled. **(**)

The study basis to be applied is assumed mainly to consist of maps, planning documents and public registers.

It is suggested that the following material be made available as far as possible for one or more of the stages of the selection procedure:

aa. Possibility of Land Acquisition

- a. Maps showing present land use, and if possible recent aerial photographs: Agriculture (soil category)
  - Forests
  - Natural resources
- b. Maps showing regulatory constraints on land use, such as areas covered by national or international nature protection regulations and conventions for archaeological and historic monuments, habitats for vulnerable and endangered species (flora and fauna), valuable landscapes, etc.
- c. Maps showing publicly owned land (state, region, province, municipality).
- d. Register and maps showing ownership of areas within or close to candidate locality.

ab. Compatibility with National or Regional Development Plans

a. Maps and descriptions showing planned development in the region and land use policy plans in general (agriculture, recreational, tourist).

ac. Environmental Acceptability

The assessment of the environmental acceptability will be part of the work carried out by the Study Team. In the first stages of the project only a preliminary assessment of the environmental acceptability is assumed. The information mentioned in the following should, however, be gathered for this topic.

It is a general assumption that both a treatment plant and a landfill will be constructed according to modern standard, i.e. with limitation of air, noise and water emissions. The conditions of interest are formulated according to this, a. Maps showing environmentally sensitive areas in general. These maps may be topographical maps, geological or hydrogeological maps, watershed area maps, or other special maps. The following special conditions should be borne in mind:

Distance from airports (bird control);

Ground water resource protection (natural low permeable layers of soil over important aquifers):

Usage of ground water in area;

Small ground water abstraction nearby (replaceability):

Distance to dug wells downstream of site;

Distance to populated areas (odour problems may reach beyond the above-mentioned 600 metres):

Specification on dense population and single dwellings;

Unsuitable surface water conditions (regularly flooded flood plains or gorges in mountains flooded in the spring);

Inappropriate slopes (risk of landslide, inappropriate construction conditions):

Description of topography;

. Description of flood risk;

. Slope stability and gradient of slope.

b. Information on meteorological conditions in the area:

Annual precipitation and distribution thereof;

Annual potential evapotranspiration and distribution thereof.

c. Predominant winds in the area:

Wind rose showing frequency of wind directions and velocities.

d. Access to landfill liner material:

.

e.

1

Distance to sufficient amounts of clay with a quality suited for liner construction (permeability <10<sup>-9</sup> m/sec., good workability and compaction major characteristics).

Distance from central point of waste collection service area (air pollution increasing with distance).

f. Public nuisance from access roads or railways:

Map showing access roads and railways in relation to populated areas an population density.

The economic feasibility will be part of the work of the Study Team. In the first stages of the project only a preliminary assessment of economic feasibility is assumed. Some basic features should be considered in the first stages and the following information be gathered for both this and the selected candidate sites for final evaluation.

a. Location of site:

.

1

- Distance from central point of waste collection are (transport costs).
- b. Area of site (For a treatment plant it should be in the magnitude of 4-6 hectares).
- c. Expected possible filling height and total volume (landfills).
- d. Life expectancy (landfills). It should be noted that a life expectancy of less than 10 years is considered unacceptable for a landfill.
- e. Accessability (need for road and/or railway construction).
- f. Purchase price of land (for example \$/ha).
- g. Availability of public service (water supply, waste water discharge related to staffing facilities, power supply).
- h. Technical considerations (technical construction problems etc. that may require additional costs).

#### J.1.4 Suggested Method of Work

The suggested method of work to get through the stages a-b mentioned in section J.1.2 are described in the following sections. The way to identify potential localization areas and sites (stage a) is described in section J.1.4a and J.1.4b, and the subsequent task of selecting candidate sites among the potential sites (stage b) is described in section J.1.4c.

Stage c, the assessment of candidate sites, is only described briefly as this is to be carried out by the Study Team in the coming phases of the project.

#### a. Identification of Potential Localization Areas

A lot of work is needed to select potential areas for localization of waste treatment and disposal facilities if one has to carefully consider every single plot of land.

In order to avoid this it is suggested to use the compiled maps mentioned under section J.1.3aa and J.1.3ab, i.e. regarding present and planned land use and regulatory constraints. If general maps on environmentally sensitive areas are available, they should be used in this preliminary phase as well.

By putting these maps in top of one another, preferably on transparent paper or plastic, areas without restrictions will emanate. This areas are potential for localization of facilities.

A map showing publicly owned land may be used as an invert - positive - indicator, because publicly owned land will often be more easily accessible than privately owned.

#### b. Identification of Potential Localization Sites

In the areas now available as potential localization areas, reasonable potential sites for establishing treatment and disposal facilities, respectively, should be established.

This is in reality the most difficult task, as there are no strict requirements at hand. The Potential Sites must be selected on the basis of consideration of a range of optimum conditions that should be met (not prioritized):

- Area of sufficient size (see J.1.3ad above, general size for treatment plants, variable depending on waste amount and filling height for landfills).
- Distance from inhabited areas preferably 600 metres for populated areas and 300 metres for single houses or more.
- Distance from airports more that 5-6 kilometres (bird control).

water and surface water).

- Localization downstream of important drinking water catchment areas (ground

- Good road and/or railway access (large roads, not much traffic in residential areas).

- No problems with flooding in wet season (steep slopes and narrow valleys/gorges should be avoided).
- Technical construction problems should not be expected (for example risk of land subsidence).
- Areas with one or few owners should be preferred (will ease land purchase). Publicly owned land may be preferred.

These criteria should result in the identification of one or more potential sites within each potential area. Preferably 10-15 potential sites for treatment plants and disposal plants should be identified within the Metropolitan area.

### c. Selection of Candidate Sites

Ð

T.

Among potential sites mentioned above, the candidate sites for further examination in stage c should be selected in stage b: Selection of candidate sites.

In order to conduct this it is suggested that a screening sheet be filled in for each of the potential sites identified in stage a. An example of a screening sheet is shown as table J.1.4a below.

The filled in screening sheets may be used either as they are or the information in them compiled into a overall evaluation sheet for all potential sites for the same purpose. In an overall evaluation sheet the description from the screening sheets would have to be condensed to one or two words or - even better - to characters on a scale from 1 to 5 - with 5 as "best".

On the basis of these screening sheets and/or the compiling evaluation sheet, the 3-4 most suitable sites for treatment plant and disposal sites must be selected.

J-7

## d. Assessment of Candidate Sites

The candidate sites will be assessed by the Study Team on cooperation with the Counterpart Team as stage c. of the selection procedure. The result of this is assumed to be a motivated list of priority for the candidate sites.

# Table J.1.4a Screening Sheet for a Potential Site

Ľ

1

It should be noted that some of the points in the table are more relevant for landfills than for treatment plants and vice versa. For example, access to covering soil and assumed maximum filling height have little relevance for a treatment plant. Such obviously irrelevant questions should not be answered. J.2 Selection of Candidate Sites for Solid Waste Disposal and Evaluation of the Sites

#### J.2.1 Introduction

The Comparative Environmental Evaluation (CEE) presented in this annex J.2 to the Final Report of the Master Plan Study on Industrial Solid Waste Management in the Metropolitan Region (MR) in Santiago de Chile aims at making a recommendation for localities in the MR to be considered as a future site for an industrial waste (hazardous waste) landfill.

The Report is structured as follows:

In chapter J.2.2 below compiled, relevant data for a comparative environmental evaluation is presented in 11 sections for each of the 11 localities selected for preliminary consideration (candidate sites). For each of the 11 localities the presentation of data and information is summed up in a preliminary evaluation at the end of each sections (section J.2.2a-l).

In chapter J.2.3 the comparative evaluation (CEE) is made, and on the basis of that a ranked - or group-ranked - list is made of the candidate landfill sites.

It should be emphasized that the evaluations and the recommendations in the following have the form of a Comparative Environmental Evaluation. The CEE has been done on the basis of information from open sources (published reports etc.) and on verbal or written information received from different Chilean administrative bodies as mentioned in section J.2.1b.

The evaluations and recommendations presented below will thus not render a full Environmental Impact Assessment (EIA) for the most promising localities dispensable. The CEE is only intended as a tool for selecting the localities to be subject to an EIA.

An Initial Environmental Evaluation (IEE) along the lines provided by JICA for the top priority sites from the present CEE is presented in Annex J.3 of the Final Report.

A summary of the below information and the comparative evaluation and recommendations can be found in section 7.3 of the Main Report together with a summary of the above-mentioned IEE.

#### Selection of Candidate Sites for an Industrial Landfill

The 11 localities which are dealt with in this report have been selected by the Chilean Counterpart. The selection guidelines provided by the Study Team in the Progress Report and described in Annex J.1 of this report were not applied, as this was deemed impossible within the strict time limit for the task. Instead, the selection has taken place in continuation of a study conducted by CRIOT, the Regional Committee of Territorial Infrastructure and Legislation of the Metropolitan Region, aiming at defining possible locations for the final disposal of <u>domestic</u> solid waste. The potential sites for industrial (hazardous waste) landfills were selected partly from the CRIOT study, partly - based on similar criteria - from the Chilean team's knowledge of sites in the Metropolitan Region.

The potential sites selected for further consideration were:

1. Montenegro (next to the potential municipal waste site selected on the basis of the CRIOT study)

- 2. Cerro Cameros
- 3. Quilapilún (Tres Orejas)
- 4. Estación Puangue
- 5. San Diego

**(**])

A

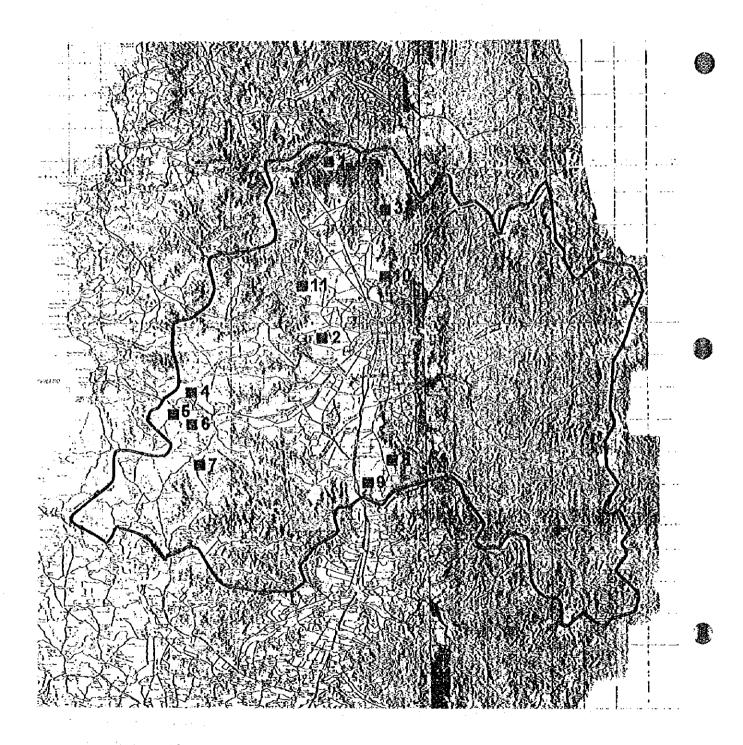

a.

- 6. Santa Amelia
- 7. Mandinga
- 8. Escorial Norte
- 9. Rincón los Rulos
- 10. Las Canteras
- 11. El Convento

The localizations of the candidate sites are indicated on the map of the Metropolitan Region overleaf (figure J.2.1a).

## b. Background for the Comparative Environmental Evaluation

As will be understood from the above, there is no detailed project for a landfill on each of the candidate sites. Nor has it been possible to gather and present a full compilation of information as is normally done when conducting an Environmental Impact Assessment. In fact, the information collected only come from open sources such as yearbooks, contemporary information etc. which could be obtained from different national and local institutions in Chile. The main sources of information have been the National Service for Geology and Mining (SERNAGEOMIN), the Metropolitan Sanitary Works Company (EMOS), the Natural Resources Information Center (CIREN). For example, the general geological descriptions for each of the sites in chapter 2 has been provided directly by SERNAGEOMIN.

Map of the Metropolitan Region with potential landfill localities indicated 

Figure J.2.1a

In order to remedy for the missing projects, the study has made a number of assumptions as to the construction, requirements etc. for a landfill intended to receive hazardous industrial waste. These assumptions are presented in sections 7.1 and 7.2 of the Main Report and further developed in Annex K of the report.

The landfill volume is calculated on the assumption that the landfill is shaped like the hills of the region, that is with a slope of 1:3 at the foot and 1:5 at the summit, averaging 1:4.

Especially for the Montenegro site, detailed investigation and design have been done by the company Kenbourne Ingenierá Ambiental S.A. ((KIASA) and DEMARCO. La Escuela de Ingeniería en Construction de la Facultad de Ingeniería de la Universidad Católica de Valparaíso has conducted an EIA for the site. Much information has been drawn from this.

### c. Limitations in the Comparative Environmental Evaluation

There are certain limitations to the present CEE:

1

First and foremost the CEE is made on the basis of a limited amount of data, and only such data that were directly available from open sources (reports, yearbooks, etc.) or from communication with public institutions such as the SERNAGEOMIN, EMOS, CIREN, and Ministries.

These data have built-in limitations as they do not provide evidence on all the aspects which should be illuminated in a CEE. But some information may be deducted from other information applying basic engineering knowledge and understanding. This has to some extent been done in the following, and it is thus evident that not all the information provided bear full scientific proof. It is also worth mentioning that the Study itself has not had the opportunity to create information, for example by executing specific on site investigations.

For site no. 1, Montenegro, a full EIA has been conducted as a basis for a decision on the establishment of a municipal waste landfill on the area (i.e. next to the area suggested for an industrial waste landfill. The information related to this candidate site is thus of a higher quality than that provided for the other sites.

In spite of the limitations of the data and the deducted evidence, the information is deemed to be of sufficient quality to allow for a preliminary (comparative)
