The required Hardware and Software for Management Information System is as follows:

Table 4.4.2-7 Required Hardware for Management Information System

Pr	oduct	Quantity
Server	UNIX machine	1
Terminal	Personal computer	36
Laser printer	· :	37
Hub		3
Router		1
Modem		17
UPS		1

Table 4.4.2-8 Required Software for Management Information System

Product		Quantity
Operating system for server	UNIX	1
Operating system for terminal	Windows	36
Database software (server)	Oracle	1
Database software (client)		36
Application software		1

The server machine and 20 terminals are installed in the STE headquarters, and 16 terminals are installed in each Province office.

4.4.3 Implementation Plan

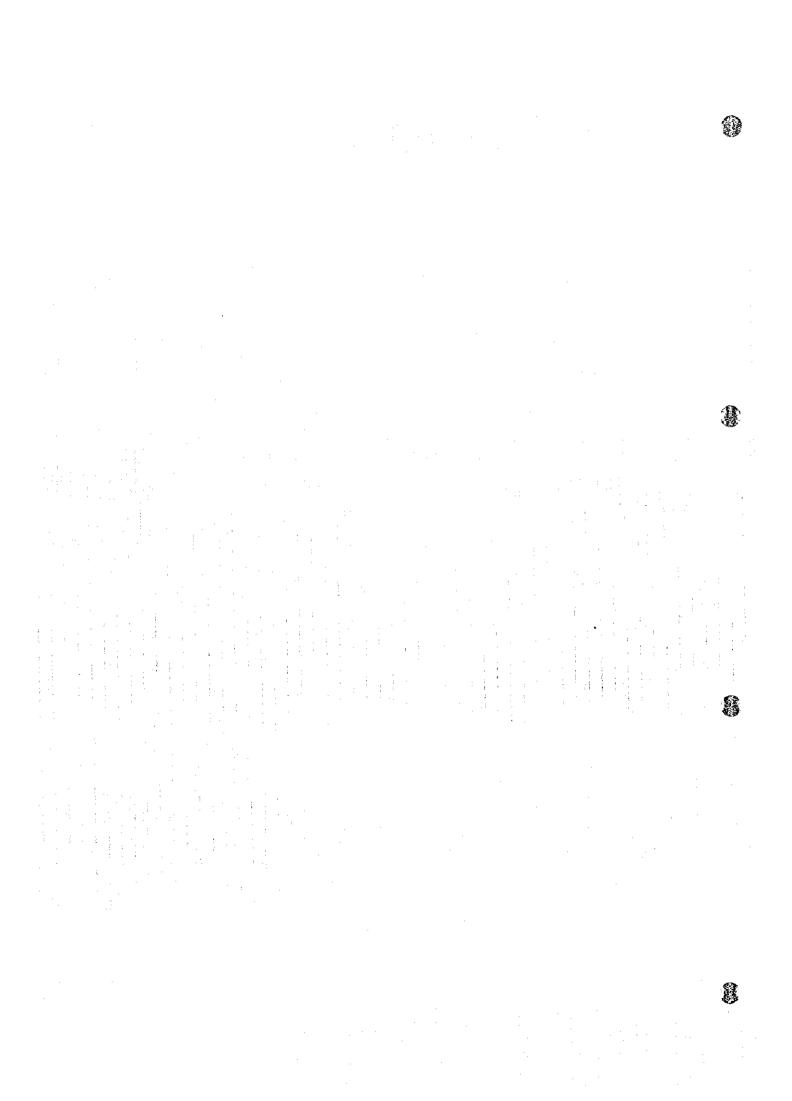

The development of new billing-center system is the most important management subject and STE should develop this system in 1996. The expansion of hard-disk capacity of the billing-center system in Aleppo will be required in 1998.

As for the telephone-center systems, we propose the installation of the systems in Damascus Rural, Quennetra, Darra and Sweda in 1997, and in Aleppo, Idleb Lattakia, Tartous, Homs, Hama, Al Hasaka, Der Alzor and Rakka in 1998.

With respect to the management information system, we propose the installation in 1997, in which year the billing-center system in Aleppo will start its operation.

Figure 4.4.2-4 Implementation Plan of Billing-center System and Telephone-center Systems and Management Information Systems

CHAPTER 5 COST ESTIMATION

This chapter estimates cost for 1996-2000, based on the Facility Plan for the Action Plan. The cost estimates based on the Facility Plan of the Master Plan is described in the Volume 1.

5.1 Transmission

纜

I

5.1.1 Methods of Cost Estimation

The following four methods are applied to each of the projects described in section 4.1.

(1) SDH systems

It is relatively difficult to accurately estimate costs of SDH systems, because they are new, and extensive field data on cost factors are not available. Therefore, this study has applied the microscopic method. First, network configurations are roughly designed. Second, necessary equipment units are selected. Then costs of the units are totaled. Note that there may be some errors in this method, because costs of equipment units obtained from manufactures are not the ones which are offered during tender and may be expensive. On the other hand, the roughness of the designs leave out some necessary equipment units, thus balancing the estimation. Overhead costs are neglected, because they are masked by the errors. In spite of the disadvantages mentioned above, it can be said that the method applied here is the best at this moment.

(2) 34Mbit/s Microwave System

Cost per (1+1) system is calculated based on the cost data provided by the 50/A project. First, the total cost of subsystems 1 to 7, including cost of multiplexers, is calculated, then divided by the total number of 34Mbit/s multiplexers used in the subsystems. This result is a figure for one side of a 34Mbit/s microwave (1+1) system, so it is doubled and a 4.5% installation cost is added. The final figure is 365,211\$ per (1+1) system.

Similarly, cost for one system addition is calculated and the result is \$160,083 per one system.

(3) Cable Burying and Laying Cost

These costs are directly dependent on Labor costs in Syria, so cost data obtained from the STE has been applied. The costs are listed below.

- (a) Burying cost (digging, faying, recovery, others) without optical fiber cable cost: 160,000 SP/ km
- (b) PVC duct laying cost including costs of PVC duct materials and manholes (8 ducts) without fiber-optic cable cost: 1,200,000 SP/ km
- (c) Cable laying cost in PVC duct: 15,000 SP/km
- (d) Cost for PVC ducts: 130 SP/ m

For long distance sections and local sections, 10% of the section lengths are assumed to be in PVC ducts and the other 90% to be directly buried. In Junction Networks, all new cables are assumed to be in PVC ducts. The Syrian Pound (SP) to US dollar exchange rate is based on 42 pounds to the dollar.

(4) 8Mbps PDH Fiber-optic System Cost

Based on the Cost Estimation Model in Figure 4.1.5-1, cost for 8Mbps PDH system with 10km new fiber-optic cable is estimated at \$159,640. For the cost estimation, field data and the cable burying and laying cost in (3) are used.

5.1.2 Overview of Five Year Plan

The cost estimation methods explained in section 5.1.1 are applied to each of the projects in section 4.1. The final estimates are listed in the table below.

Table 5.1.2-1 Transmission Costs for 1996-2000

	[US\$]
Long Distance Network	25,000,000
Junction Networks	16,100,000
Long Local Sections	4,500,000
Local Sections with Existing Systems	2,300,000
Local Sections to small Exchanges	57,500,000
Network Management Systems	3,000,000
Total	108,400,000

5.2 Switching for the PSTN / ISDN

5.2.1 Cost Structure in Syria

T.

In the switching sector, the following cost components are to be considered

- Costs to be borne in foreign currency (US \$)
 - Equipment costs, (incl. Spare parts)
 - Installation supervision costs
- Costs to be borne in local currency (Syrian Pounds)
 - Planning costs,
 - General overhead costs (specification, contract negotiation, commissioning),
 - Installation costs,
 - Costs for buildings and land.

Due to the fact that installation is being fully performed by local staff, all feasible possibilities to increase the locally added-value portion seem to be exhausted.

5.2.2 System Cost Estimation

The contract 40 A was the last representative contract, which can be used to analyze the present cost for switching equipment in Syria. The newest contract on 125,000 line units comprises almost only of remote units, which make use of already existing host switches, and is therefore not representative for overall costs in switching.

However, the world market prices for switching equipment still show a downward trend, but with decreasing momentum.

Subsequently, estimated costs as expected for the Eighth National Five-Year Plan are given per line (unit) for the different types of exchanges. In the foreign cost portion are included: (M)DF, power supply, batteries, diesel, air-conditioning, raised floor spare parts and installation supervision. The local currency portion contains: planning, project overhead, installation, testing, buildings and land.

Not included in the switching cost here are costs for supporting functions such as OMC hard- and software, circuit board repair center, special training measures, etc.

The local currency portion is expressed in US \$ based on an exchange rate of 42 Syrian Pounds per US \$

Remote Units and Expansion of Existing Local Exchanges inside the Final Capacity

	US \$	Syrian Pounds
Foreign currency portion	100	-
Local currency portion	30	1,260
Total per RU/LE line unit	130	

New Local Exchanges and Expansion Beyond the Present Final Capacity

	US \$	Syrian Pounds
Foreign currency portion	155	_
Local currency portion	33	1,386
Total per LE line unit	188	-

Long Distance (STD) Exchanges

	US\$		Syrian Pounds
Foreign currency portion		158	-
Local currency portion		25	1,050
Total per STD line	National	183	•

International Exchanges (IGE)

	US \$	Syrian Pounds
Foreign currency portion	300	
Local currency portion	25	1,050
Total per IGE line	325	-

5.2.3 Cost Trend Estimation

Since the start of market availability, the prices for digital switching equipment have shown a very strong downward trend (80% price reduction in the last ten years). In general it is assumed that a downward trend will continue in the future. However, this trend will be much weaker than in the past. A price decrease is estimated at 1 - 2% per year.

For the local currency portion, an upward trend is estimated at approximate 6 - 8% per year due to increasing wages and inflation.

As a summary result we predict constant prices for switching equipment during the Eighth National Five-Year Plan in conjunction with increasing functionality (new subscriber features, service switching point functionality, SS7 INAP, TMN (Q) interfaces, management intelligence, etc.)

5.2.4 Unit Cost Estimation

1

If a telecommunications network is expanded continuously in a balanced way, i.e. all components are provided in accordance with the demand and no over-provision is made of particular network parts (e.g. IGE or STD exchanges), a simplified cost estimation is possible, based on unit cost.

Unit costs are obtained by calculating all system costs in basic units, in the context of switching the subscriber line unit in the local exchange.

For Syria the following unit cost per subscriber line unit (switching cost only) is estimated:

	US\$
Local Switching	130
Long Distance Switching Portion	15
International Switching Portion	8
Buildings (portion utilized for switching)	15
Installation, Testing (local portion)	33
UNIT COST per Subscriber Line Unit	201

5.2.5 The Eighth National Five-Year Plan Overview

In the following table, the investment costs for switching equipment are estimated based on the figures indicated in the Facilities Plan (section 4.2) of this Report and on the cost estimations above.

For the calculations, system costs have been used in accordance with section 5.2.2, this is because owing to the relatively large portions for older system replacement, unit costs are not applicable. For the regular network expansion, 50% as remote units and expansion in existing local exchanges inside the present final capacity, and 50% in new local exchanges and expansion beyond the present final capacity have been assumed.

(Unit: US\$)

	Amount	Price per Line	Total Cost
Regular Local Exchange Expansion	1,532,500	159	243,667,500
Replacement of EMD	221,000	188	41,548,000
Long Distance Exchange Expansion	36,750	183	6,725,250
International Exchange Expansion	-	<u>-</u>	-
TOTAL SWITCHING INVESTMENT			292,000,000

5.3 Subscriber Network

5.3.1 Unit Cost

In this section, cost estimations are given for the particular network components described in section 4.3 as a basis for the financial evaluations.

Based on information obtained from STE counterparts, the average costs for the physical subscriber network are estimated at US\$ 370 per Switching Line Unit (S.L.U.).

In addition, the unit cost includes the civil works investment, and its breakdown is as follows:

Unit cost per primary cable pair

US\$ 86 (86 x 1.5 = US\$ 129 per S.L.U.)

Unit cost per secondary cable pair : US\$ 107 (107 x 1.5 x 1.5 = US\$ 241 per S.L.U.)

5.3.2 The Eighth National Five-Year Plan

A summary of the investment for primary and secondary cable pairs respectively to be installed until the year 2000 per region is shown in Table 5.3.2-1 and Table 5.3.2-.2 The investment necessary for the subscriber network to be installed until the year 2000 is shown in the following table.

(Unit: Millions of US Dollars)

Primary cable pairs	176.42
Secondary cable pairs	329.25
Total	505.67

176,422,244

Table 5.3.2-1 Cost Estimation: Additional Investment Required for Primary Cable Installation in USS

5.4 Computerization

5.4.1 Costs for the Three Systems

In estimating the cost for the STE computerization the preconditions are as follows;

- To procure hardware in Syria.
- To utilize and customize packaged software.
- To exclude construction costs for new builgings because it is possible all of the systems are installed in existing structures.
- To exclude communications expenses because the network facility is owned.

According to the facilities plan from 1996 to 2000, costs for the three Systems are shown in Table 5.4.1-1, Table 5.4.1-2 and Table 5.4.1-3.

Table 5.4.1-1 Necessary cost of Billing-center system (US\$)

Hardware	283,700
Software	29,200
Total	312,900

(Note: In 1998, additional hard disk will be installed in order to expand the capacity which accommodate the increase of subscribers, and the cost of additional disk is \$ 5,600.)

Table 5.4.1-2 Necessary cost of Telephone-center systems

Hardware	are 5,217,800		
Software	2,952,500		
Total	8,170,300	1 1	

Table 5.4.1-3 Necessary Cost of Management information system

Hardware	252,500	
Software	39,100	
Total	291,600	

5.4.2 Total Cost of the New Computer Systems

Beside hardware cost and software cost, we need consider system installation cost. It is calculated according to this formula; Cost of hardware * 5% (including access control equipment, cables and other small devices). The total cost of new billing-center system,

telephone-center systems and management information system from 1996 to 2000 is about \$ 9 million.

Table 5.4.2-1 Total cost of the new computer systems

System	Cost (\$)
Billing-center system	318,500
Telephone-center system	8,170,300
Management Information system	291,600
Installation cost	287,700
Total	9,068,100

5.5 Cost Estimation Summary

The total investment cost for the Eighth National Five-Year Plan is listed in Table 5.5-1.

Table 5.5-1 Total Cost Estimation Summary for the Eighth National Five-Year Plan

Facilities / Systems	Estimated Cost
Transmission System	108.4
Switching System	292.0
Subscriber Network	505.7
Computerization	9.1
Total	915.2
<u> </u>	

CHAPTER 6 FINANCIAL ANALYSIS

The Financial Analysis for the Action Plan herein is based on the Facilities Plan and Cost Estimation in accordance with the Action Plan. Financial Analysis based on the Master Plan should be referred to the Volume 1.

6.1 Purpose

In this chapter the financial viability and potential profitability are evaluated, and financial analysis has conducted just for reference.

In the Detailed Plan, the Project, mainly on Damascus City, will be evaluated not only from financial point of view but also from economic point of view.

Refer to the Chapter 4.4 on computerization for evaluation of business process improvements offered by computerizing operations.

6.2 Procedure

1

Financial analysis of the project is based on a cost versus profit analysis using an internal rate of return. Since most of the STE's revenue and expenditure are settled in US dollars, all the revenues and costs concerning the project were calculated in US dollars. The project was evaluated using the following methods:

- (1) Estimation of capital expenditure and operating expenditures (cash outflow)
- (2) Estimating operating revenue (cash inflow)
- (3) Creation of cash flow table and calculation of financial internal rate of return (FIRR).

6.3 Premises and Assumptions

The first step is to identify the premises and assumptions for each project. Realistic and simple assumptions make evaluation more reliable and accurate. The basic premises and assumptions of this evaluation are described in the following sections.

(1) The Duration of the Project's Revenues

The duration of the project revenues is longer than the duration of the project's investments. Though the project duration is until 2000, the duration of revenues was calculated until 2010. The reasons of it are as follows;

- a) The lives of facilities are mainly 10 years and 20 years (e.g. EMD switches), so it is reasonable to settle the duration of revenues as 10 years after the end of investments.
- b) From the worldwide points of view, it is general to settle the duration of revenues as about 10 years after the end of investments.

(2) Inflation

The effects of inflation were not considered. Although price changes affect both project costs and revenues, prices that increase at the same rate at home and abroad mean they maintain the same levels.

(3) Revenues and Costs Estimation

The present tariff rate (1995) was used to estimate the revenues in the project.

6.4 Estimation of the Project Revenues

The project revenues consist of telephone installation fees, basic yearly charges, local call charges, long distance call charges, international call charges, facsimile installation fees, telex charges, telegraph charges and others.

(1) Revenue per main line from 1992 to 1994

The number of main lines, revenues and revenue per main line from 1992 to 1994 according to STE statistics are shown in Table 6.4-2. OECD countries' revenue per main line are shown in Table 6.4-1.

Table 6.4-1 OECD Countries' Revenue Per Main Line (1992)

(US\$)

1994	688,500	154,600,000	224.5	38.7
1993	550,000	102,200,000	185.8	38.7
1992	513,000	75,480,000	147.1	-

(2) Revenues Estimate for the Eighth National Five-Year Plan

The annual project revenue is estimated as shown in Table 6.4-3, by forecasting the number of mainlines, the revenue per main line, traffic distribution, and depreciation of facilities.

Because the average life of facilities is considered 20 years, revenue will decrease as facilities wear down gradually.

Table 6.4-3 The Estimate of the Revenue

Year	Annual Increment	Number of Main Line	Revenue (US\$)
1996	320,000	320,000	71,840,000
1997	320,000	640,000	143,680,000
1998	320,000	960,000	215,520,000

2010	-+	•	179,600,000

6.5 Cost Estimate for the Eighth National Five-Year Plan

In general, costs consist of investment costs, which include construction and procurement costs, consulting fees etc, operation and maintenance costs, working capital and taxes.

(1) Investment Costs

Investment costs examined and estimated in this report include the prices for facilities, equipment, land and buildings, vehicles, construction and installation fees, and consulting fees.

Investment costs for the project are shown in Table 6.5-1

Table 6.5-1 Investment Costs

·	(Thousands of US\$)				
Year	Transmission	Switching	Subscriber Network	Computerization	Total
1996 to 2000	108,400	292,000	505,674	9,068	915,142

(2) Operation and Maintenance Costs

Expenses for the operation and maintenance of telecommunications networks consist of personnel costs, administration costs, and repair costs.

Table 6.5-2 Cost per Main Line (1992 - 1994)

Year	Number of Main Lines	Expenses (US\$)	Cost per Main Line (US\$)	Increment (US\$)
1994	688,500	65,640,000	95.34	32.83
1993	550,000	34,380,000	62.51	6.55
1992	513,000	28,710,000	55.96	-

Table 6.5-3 Operation and Maintenance Costs in 1994

 Payment to International Operator	Personnel	Utilities	Others	Total
22,330,000	27,050,000	3,190,000	13,070,000	65,640,000

Generally speaking, "cost per main line" tends to decrease as telecommunication technology improves; however, in the case of Syria, "cost per main line" went up between 1992 and 1994.

6.6 Working Capital

Working capital can be recovered within a short time through business activities. The capital includes current deposits as eash on hand, and accounts receivable as funds necessary until call charges are collected. Although working capital is calculated as an annual expense, it should be recovered during the final year of each project.

6.7 Taxes

STE pays about 58.5% of annual profits to the government as a tax obligation. Because the STE is a government organization (public corporation), the FIRR should be calculated on the basis of pre-tax revenue.

6.8 Results of Financial Analysis

The FIRR is the discount rate that makes the total present value of investment costs equal to the total present value of annual profit.

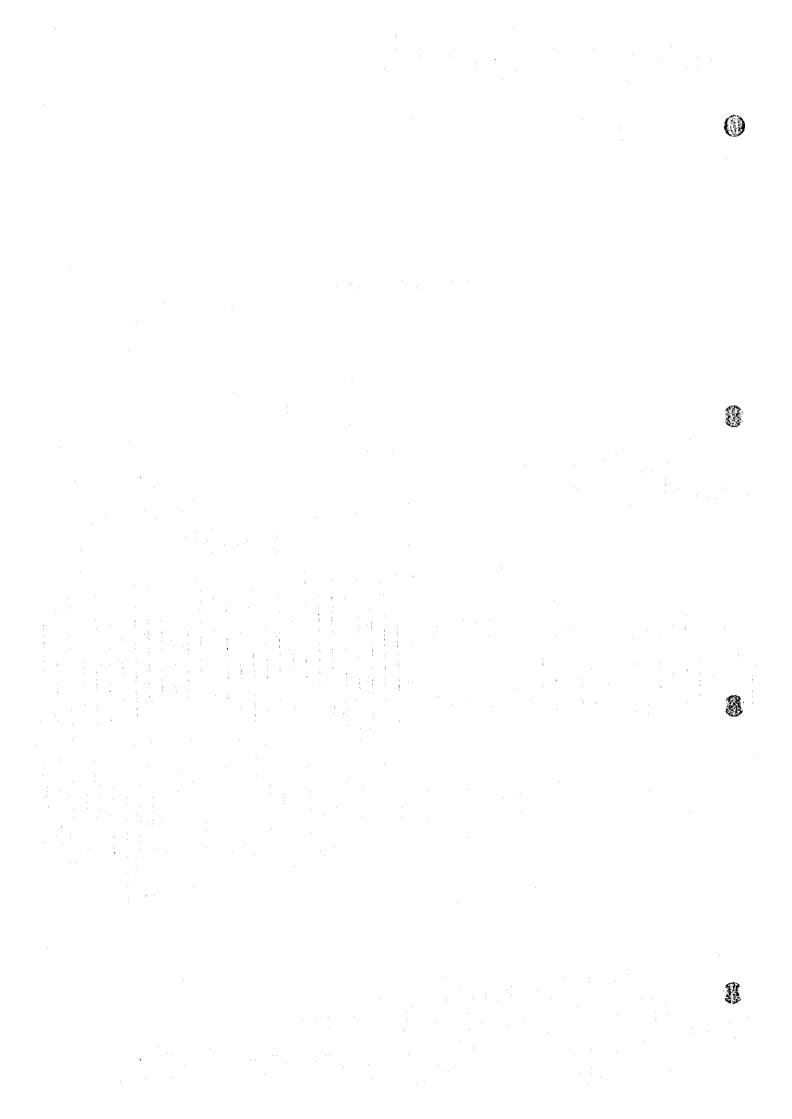

Table 6.8-1 shows a tentative revenue and expenditure statement. The Eighth National Five-Year Plan Project will have the 10.46% tentative internal rate of return.

Table 6.8-1 Tentative Cash Flow Table

PART 2 DETAILED PLAN

CHAPTER 1 INTRODUCTION

1.1 Introduction

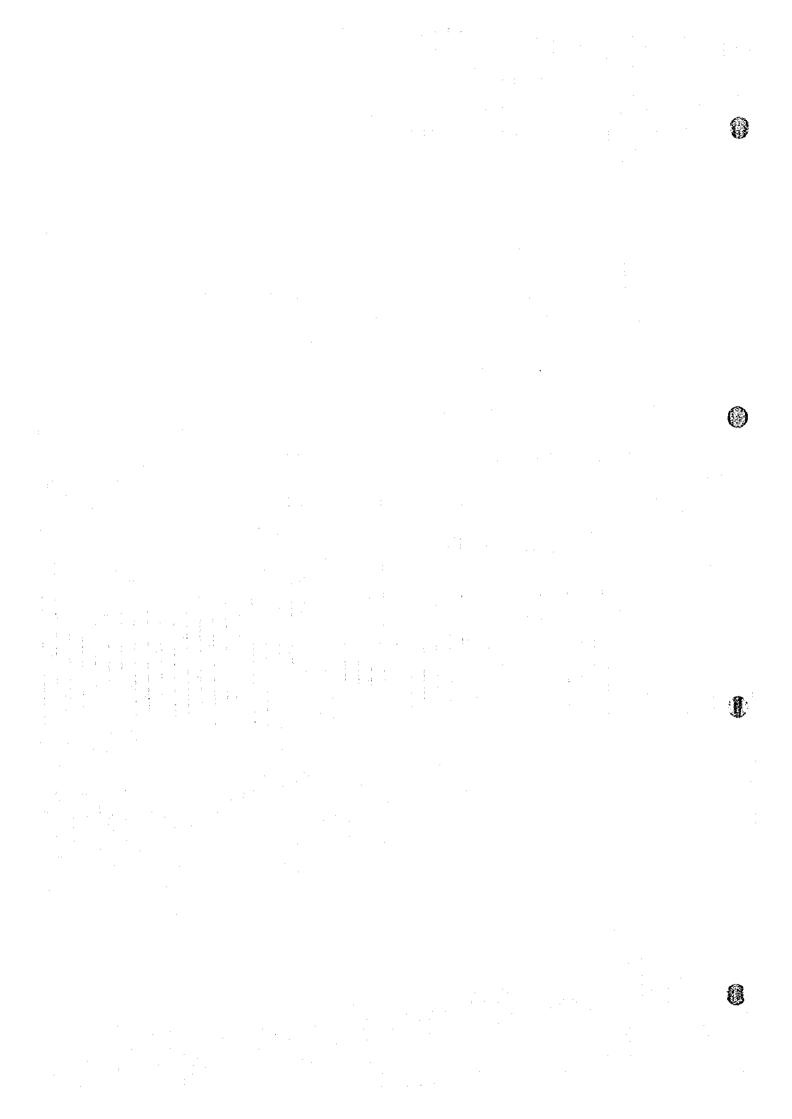

This Report describes the findings and results of the work in Syria on the Detailed Plan of the selected projects, which was carried out from February to August, 1996, based on the Eighth National Five-Year Plan as Part 1 in this Volume 3, which was formulated from December, 1995 to March, 1996 prior to this study.

1.2 Objectives of the Study

The objective is to study in detail the target projects based on the Action Plan.

The target projects are as follows:

- (1) Expansion and improvement of the telephone network
- (2) Introduction of Mobile Telephone system
- (3) Introduction of Packet Switched Data Network system
- (4) Introduction of three (3) Computerized systems
 - Telephone-center System
 - Billing System
 - Management Information System

CHAPTER 2 SELECTION OF TARGET PROJECTS

2.1 Policy of Selection

2.1.1 Relation with the Master Plan and the Action Plan

The long-term plan covering up to the year 2010 for development and improvement of the telecommunications network in Syria was studied and made as the Master Plan by Japan International Cooperation Agency study team (hereinafter referred to as "the Study Team") in 1995. The Master Plan includes many telecommunications systems such as telephone network expansion and introduction of mobile telephone network, data transmission network and computerized system, which will provide a total telecommunication network that will meet customers' requests and keep up with the times and the national economic development.

On the other hand, the Action Plan was prepared to review the Eighth National Five-Year Plan (1996 to 2000), which was settled on by Syrian Telecommunications Establishment (hereinafter referred to as "STE").

The target projects for the Datailed Plan as a feasibility study in the Action Plan should be selected based on the Action Plan.

2.1.2 Criteria for Selection

Basic criteria for selection of telecommunication networks development should be as follows:

- (1) To expand the telephone network to satisfy high demand
- (2) To introduce new services with high urgent demand
- (3) To replace/renew older facilities which are obstacle to service quality and O/M works
- (4) To secure stable network services
- (5) To improve productivity of daily work

(6) To improve productivity of administration and management

2.1.3 The Target Systems

The following systems should be selected as the target systems from viewpoints of urgent fulfillment of the telephone demand, earlier introduction of new services and improvement of customer services and management:

- (1) Telephone network expansion
- (2) Mobile telephone system
- (3) Packet switched data network
- (4) Computer system

2.1.4 Areas of Projects

Areas or locations for the project should be settled from viewpoints of the following subscriber categories:

- Administrative/Governmental group area
 - Industrial/Business group area
- Commercial group area
 - Residential group area

2.2 Selected Target Projects

Areas and locations of target projects for the Feasibility Study were selected based on the above policy:

2.2.1 Telephone Network Expansion

Expansion and replacement of telephone network systems in all Damascus city except for the rural area:

(1) Switching system (including replacement of older exchanges, expansion of STD and INTS)

- (2) Subscriber network
- (3) Transmission system
- 2.2.2 Mobile Telephone System

Damascus and Aleppo areas including main roads (main parts of the western Syria)

2.2.3 Packet Switched Data Network

The five big cities (Damascus, Aleppo, Homs, Ilama, Lattakia)

- 2.2.4 Computer System
- (1) Billing System

- Center system : Aleppo

· Telephone center: The five big cities

(2) Telephone Center System

The five big cities (except for Damascus)

(3) Management Information System

The five big cities and STE's headquarters

The target system projects are shown in Table 2.2.4-1.

Table 2.2.4-1 Selected Target System Projects

System	Area/locations	Remarks

5 big cities: Damascus, Aleppo, Hama, Homs, Lattakia(except for rural areas)

2.3 Target Year

The target year for this project should be decided by each system, taking into account the service commencement year as early as possible, which will be assumed on conditions of the urgency and the duration of finance, tendering and installation for each system.

As a result of the study, the target year for each system in this project is shown in Table 2.3-1.

The lead time for provisioning for each system is described in Chapters 4 - 7.

CHAPTER 3 FUNDAMENTAL NETWORK PLAN

- 3.1 Network Structure
- 3.1.1 International Network
- (1) Present Network

At present there are two (2) INTSs (International Switches) in Damascus and Aleppo, and each INTS has its own set of international destinations respectively. Low-traffic destinations, however, are reached only from a certain INTS, so inter-INTS circuits are established between the two INTSs. International calls from all STDs in Syria are routed to both INTSs, but because of the difference between the capacities of the Damascus and Aleppo INTSs, the traffic volumes from/to the geographically close STDs, and the number of destinations available from each of the two INTSs about 90% of the traffic is distributed to the Damascus INTS.

(2) Network Structure in Damascus city

International calls from/to LEs (Local Exchanges) in Damascus city are routed to the Damascus INTS and the Aleppo INTS via Damascus STD.

The traffic distribution ratio should be 60% to the Damascus INTS and 40% to the Aleppo INTS by the year 2000 step by step from the viewpoints of the security.

The international network structure and routing for year 2000 is shown in Figure 3.1.1-1

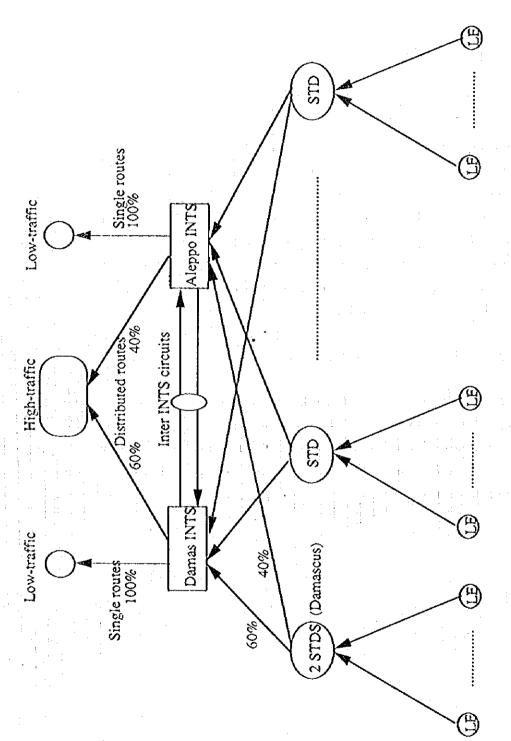

Figure 3.1.1-1 International Network Structure and Routing for the year 2000

3.1.2 Long Distance Network

(1) Existing National Telephone Network

The existing network structure has the four(4) level hierarchy, the forth level is divided into five(5) one-level areas in Syria as shown in Figure 3.1.2-1.

Digitalization of telecommunications system will promote a minimum hierarchy structure because of decreasing the circuit cost and simplifying the structure. In Syria transition from the four(4) level hierarchy to the three(3) level hierarchy is in progress in order to eliminate the 2-level stage of Nabek and Zabadani in Damascus region.

(2) Long Distance Network in Damascus Region

For long-distance call connection, the Damascus region is, as shown in Figure 3.1.2-2, divided into the following three areas:

- Damascus city area

- Damascus rural area
- Damascus region area

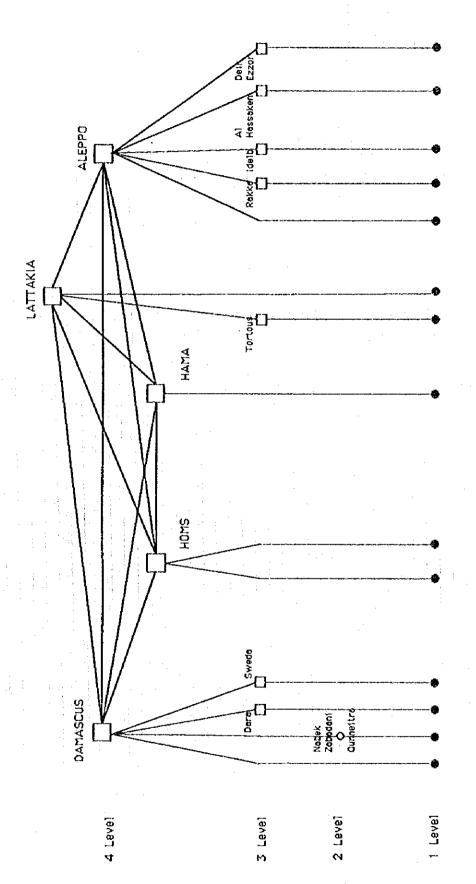

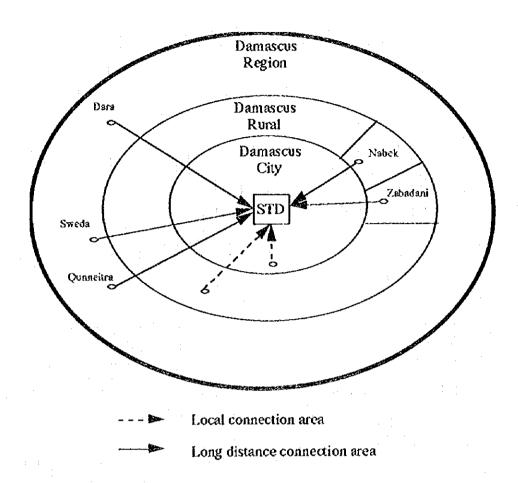

Figure 3.1.2-1 Existing Network Structure for National Telephone Network

9

0

1

Figure 3.1.2-2 Damascus Region

To study the future network structure in Damascus region, the following considerations should be taken as basic conditions of the region:

- The existing routing is not simplified based on a certain logical routing method.
- Intensive increase of subscribers and traffic volume in Damascus city and its suburb in the rural area is foreseen in near future.
- Many small automatic exchanges including RSUs are planned to replace manual exchanges in the rural and region areas.

- The need for network security increases with network size, and security thus bee omes critical for a large network.
- The existing circuits and LT (local transit exchange) function should be utilized as effectively as possible from the viewpoints of maximum dimensioning of exchanges.
- The existing and future transmission routes for each district block should be taken into consideration for the security reason.

Taking into consideration the above, the new network structure and routing for Damascus region should be as follows:

- To establish a new STD at a new building separated from the existing Al Nasser
 STD from point of view of security and expansion of circuits.
- To distribute the traffic and routes to two(2) STDs at the ratio of 50% to 50% in principle.
- To divide the city and rural area into seven(7) blocks in the rural area according to the transmission routes.
 - To centralize the small circuits groups from the small exchanges (about less than 10,000 subscribers) in a block to the exchange which has transit function (combined LE/LT) to minimize the circuits cost, and to carry the centralized traffic to STDs via this exchange.

The long distance network structure in Damascus region as a result of the above should be Figure 3.1.2-3.

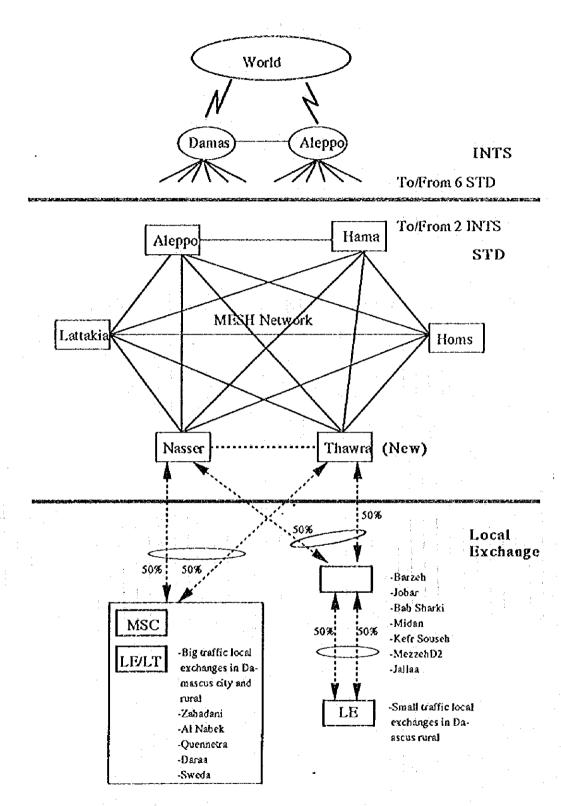

Figure 3.1.2-3 Long Distance Network Structure in Damascus Region

3.1.3 Local Network in Damascus City

(1) The Present Network

Damascus city has a large multi-exchange local network and at present the network will be classified as an unstructured network from the following reasons:

- New exchange and expansion plan not based on a certain fixed network plan
- New routes setting from viewpoints of the existing routes without the fixed routing standards

The present routing in Damascus local area is shown in Figure 3.1.3-1.

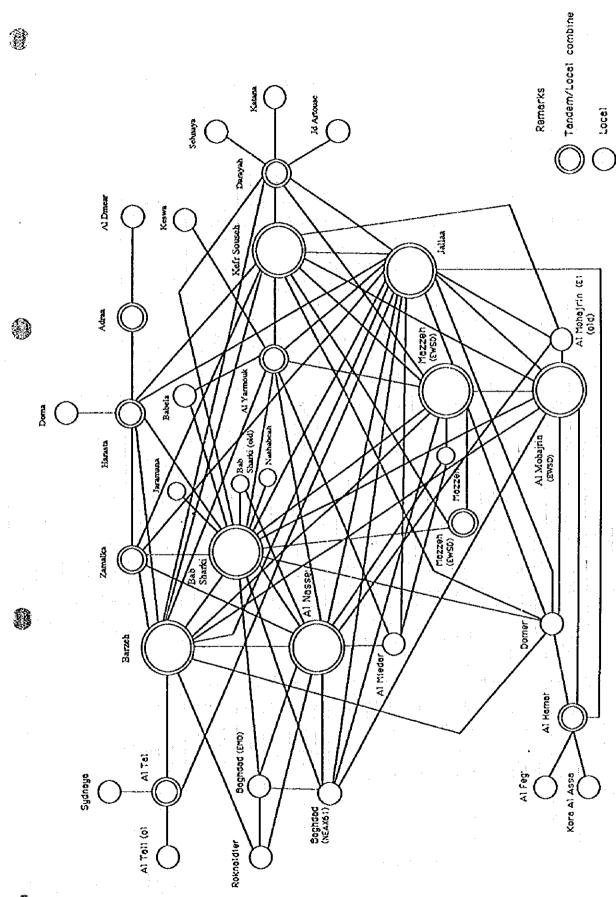

Figure 3.1.3-1 Routing in Damascus Local Area

Ţ

(2) Considerations for the Future Network

The large expansion of the network and increase of big number of subscribers towards the year 2000 will need an optimum, i.e. a simple, effective and high security local network. For restructuring the existing network the following considerations should be taken:

- The local network for local connection calls will have a big number of automatic exchanges (about eighty) which are located over Damascus city and its rural.
- There will be a lot of big exchanges which have subscribers more than 20,000 in Damascus city and its suburb, and their traffic quantities may increase hugely.
- On the other hand, there will be a lot of small exchanges which have subscribers less than 3,000.
- The rural area is divided into several district blocks on the transmission routes and the security of the network, and there exists a gate way exchange as a node point in each block.
- The security of the network is absolutely needed according to becoming a huge network.
- The transition from the existing network to the restructured network should be able to carry out easily step by step.

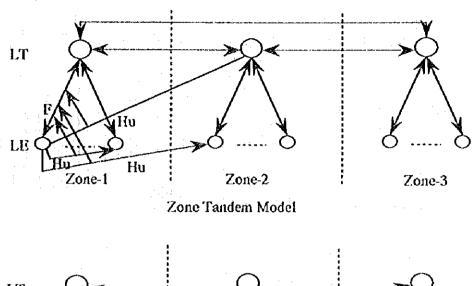

(3) The Proposed Local Network Structure in Damascus

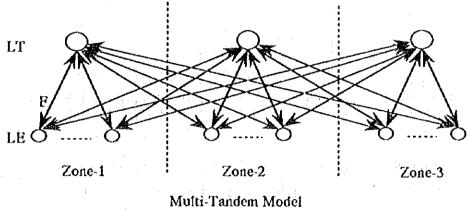

Generally the optimum network is to be studied to minimize basically both the switching and transmission costs, however, at the same time, other considerations such as easy planning, easy operation and maintenance, good security should be taken.

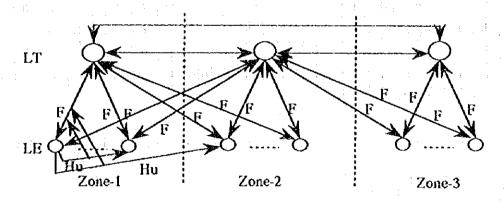

Here the following three models of local network structure were studied and simulated using estimated traffic data for Damascus area:

- Zone tandem model
- Multi-tandem model
- Combined Zone and Multi-tandem model

The three models are shown in Figure 3.1.3-2.

Combined Zone and Multi-Tandem Model

Figure 3.1.3-2 Local Tandem Model

[]

Table 3.1.3-1 Summary Features of Each Model

	Number of circuits	Security	Operation & maintenance	Combined LT & LE
a) Zone tandem model	less than b)	good	medium	possible
b) Multi-tandem model	too many	excellent	simple and easy	impossible(dedi cated transit exchange)
c) Combined Zone and multi- tandem model	less than b) and more than a)	excellent	alittle complicated	possible

Based on the above results and considerations for the future network described in (2), the proposed local network structure should be "Combined Zone and Multi-Tandem" model.

As a home exchange, the zone tandem (transit) exchange should have about twenty (20) LEs, each with two (2) home exchanges (a main home tandem and a sub home tandem) on final routiong path ways.

The Damascus city and its rural areas are divided into seven(7) blocks as tandem area according to geographical area, appropriate number of LEs and the transmission routes.

The tandem exchang switches long distance calls from the small exchanges in its own block area to 2 STDs.

The proposed restructured local network in Damascus area is shown in Figure 3.1.3-3.

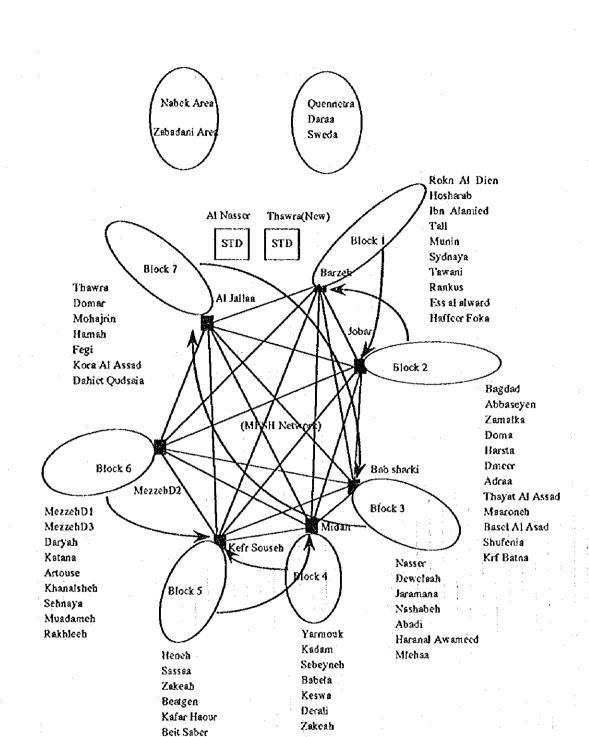

Figure 3.1.3-3 Proposed Local Network in Damascus Area

Home LT

Danaje

Block

Legend

: LE/LT

Kozlanca

Hejanee

Basel Al Asad

Another Home LT

3.2 Routing Plan

The routing should be basically "far to near rotation method" and the routing criteria for traffic volume is as follows:

- A direct high usage route between LE and LE : more than 20 crl.

- A direct final route between LE and LE : more than 90 crl.

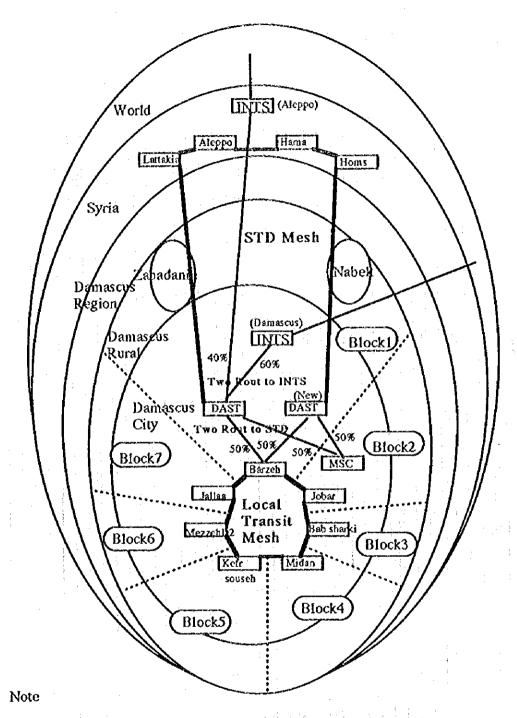

A final route between LE and 2 home LTs : all final traffic and

over-flow traffic from

high usage routes

3.3 Proposed Integrated Network in Syria

The proposed integrated network structure and routing in Syria as the summary of the study will be shown in Figure 3.3-1.

- 1 Two(2) Routs Between seven(7) Local Tandems and two(2) DASTs 2 Two(2) Routs Between six(6) STDs and two(2) INTSs
- 3 Seven(7) Local Tandems are connected with Mesh Network
- 4 Six(6) STDs are connected with Mesh Network except between two(2) DASTs

Figure 3.3-1 Proposed Integrated Network in Syria

3.4 Numbering Plan

3.4.1 National Numbering Plan

The national numbering plan is as follows:

(1) Structure of numbering

(2) Prefix code

0X: National, 09: New services, 00: International

3.5 Signaling Plan in Damascus City

(1) The present signaling system

The current signaling systems between exchanges in Damascus area are employed as shown in Table 3.5-1.

Table 3.5-1 Signaling systems in Damascus area

	EWSD	NEAX61	EIOA	EMD
	No.7	MFC	MFC	DP
EWSD	(BW)	R2	R2	3W
	MFC	MFC	MFC	DP
NEAX61	R2	R2	R2	3W
	MFC	MFC	MFC	DP
E10A	R2	R2	R2	3W
	DP	DP	DP	DP
EMD	3W	3W	3W	3W

(2) Signaling system in this project

In this project, new establishment of digital exchanges, replacement from EMD exchanges to new digital exchanges and expansion of existing digital exchanges are planned. Accordingly signalling systems to be introduced should be ITU CCS (Common Channel Signaling System) No.7, which has the following features:

- High speed signal transmission
- Signal transmission during conversation
- A wide variety of signals and a large signaling capacity
- Both way speech circuits operation

All circuit groups between digital exchanges where SS7 ISUP is applied should be operated as both way groups.

The present associated mode for signaling link will be employed until a quasi-associated mode is introduced in near future. These transfer modes are shown in Figure 3.5-1.

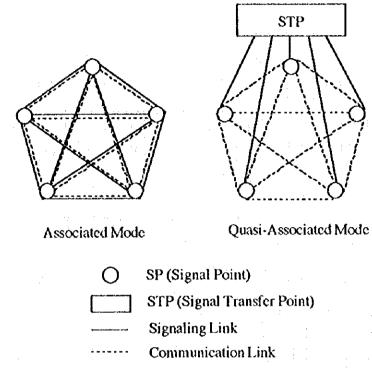

Figure 3.5-1 Signal Transfer Mode

3.6 Charging Plan

3.6.1 The Present Charging System

The present charging systems are as follows:

(1) International call

AMA (Automatic Message Accounting) system is applied at the STD exchanges (EWSD), to which ID (Identification) is transmitted from all local exchanges except from an EWSD type exchange, which has an AMA system itself.

Calls are charged by calculating call duration and destination according to the tariff.

From the exchanges which have the AMA system, MT (Magnetic Tape) is sent to the billing center once per month.

(2) Long distance call

The same AMA system as for international calls is applied to all STD exchanges.

(3) Local call

Electronic/mechanical meter system is applied to each local exchanges.

From the exchanges which have the electronic meter system, MT (Magnetic Tape) is sent to the billing center once every three(3) months.

The charging systems by each local exchange type are shown in Table 3.6.1-1.

Table 3.6.1-1 Charging System by Each Exchange

	International call	Long distance call	Local call
EWSD	AMA	AMA	Electronic meter
NEAX61	AMA(atSTD)	AMA(atSTD)	Electronic meter
E10A	AMA(atSTD)	AMA(atSTD)	Electronic meter
EMD	AMA(atSΓD)	AMA(atSTD)	Mechanical meter

3.6.2 Charging Plan in This Project

In this project, new establishment of digital exchanges, replacement from EMD exchanges to new digital exchanges and expansion of existing digital exchanges are planned. Accordingly charging system to be introduced should be AMA system for international and long distance call, and electronic meter system for local call.

3.7 Synchronization Plan

3.7.1 Clock Distribution System

A master-slave synchronization system has been employed in the Syrian digital network.

3.7.2 Stability of Clock

The stability of the master clock and back-up oscillators in each hierarchy stage will be as follows:

Master clock (International switch)	10-12
STD (Toll transit switch)	10-8
LS (Local switch)	108
RSU (Remote switch unit)	10-6

3.7.3 Clock Distribution Network

The clock distribution network is shown in Figure 3.7.3-1.

In near future Aleppo INTS will have a submaster clock as a stand-by for the master-clock in Damascus INTS. In case of master-clock failure, the sub-master clock will distribute a clock signal to the entire Syrian digital network.

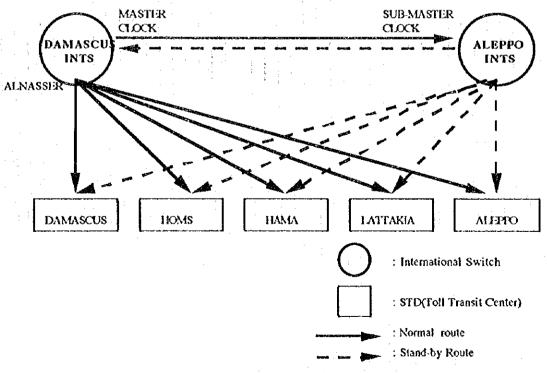

Figure 3.7.3-1 Clock Distribution Network

3.8 Technical Standards of Network

3.8.1 Connection Loss

The loss probability in circuit groups is allocated, as shown in Figure 3.8.1-1, on the basis of ITU-T Recommendation E.520.

Note:

- 1. Normal load: Mean of the 30 highest working days in a 12-month period.
- 2. High load: Mean of the five highest days in the same 12-month period.

If loss probability allocated to each connection of a digital transit exchange and terminating exchange is 0.001, the total loss probability between exchanges on both ends becomes 0.007, as shown in Figure 3.8.1-1.

The ITU-T recommends a loss probability of 0.05 (one side) for domestic data switching networks (Rec. X.131). This means that the end-to-end loss probability of digital switched networks should not exceed 0.1.

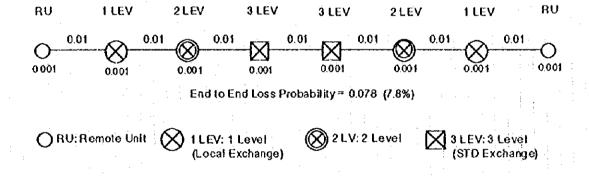

Figure 3.8.1-1 Connection Loss Allocation(Maximum)

3.8.2 National Transmission-Loss Allocation

Figure 3.8.2-1 shows the national transmission-loss allocation in the digital network in Syria.

The subscriber line loss does not exceed 8 dB at 800 Hz, and the maximum direct current loop resistance of the line is 1,500 to 1,700 ohms.

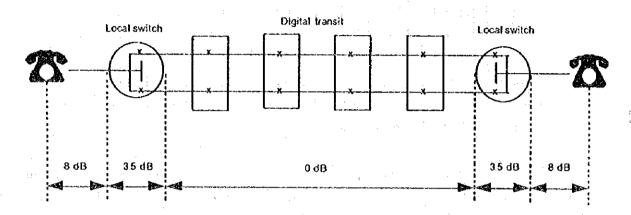

Figure 3.8.2-1 National Transmission Loss Allocation

3.8.3 Target Values of Network Quality

The target values for network quality are listed in Table 3.8.3-1.

Table 3.8.3-1 The Target Values for Network Quality

Network Quality	Grade of Service	Target Values	Related ITU-T Recommendations
	Initial address message delay (for signaling system No.7 netwowks)	Total delay 4 sec. International 1.5 sec. National 2.5 sec	E723
Connection Performance	Answer message delay (for signallings) system No.7 network)	Total delay 2.5 sec. International 1.0 sec. National 1.5 sec.	E723
	Probability of end-end blocking	Local connection 2% Toll connection 3% Intenational 5% connection	E721
Transmission	Transmission Loss for Digital Links	Totalloss 0 dB	. :
Performance	Bit Error Ratio for Severely Errored Seconds of Digital Network	Fewerthan 0.2% of one second intervals to have a bit error ratio worse than 1x 10 ⁻³	G821

CHAPTER 4 TELEPHONE NETWORK EXPANSION PLAN

4.1 Demand Forecast and Fulfillment Plan

In this Study, the demand of Damascus city is forecasted and the fulfillment plan is made through the microscopic survey and study, referring to the demand forecast and fulfillment plan of the whole of Syria made in the Action Plan through macroscopic point of view.

Table 4.1-1 shows the demand forecast in the Action Plan.

Table 4.1-1 Demand Forecast in the Action Plan

						 (Uni	t : TI	iousands
	1996	1997	1998	1999	2000	2002		2005

Whole Country	3074.0	3274.0	3475.0	3677.0	3876.0	 4265.0		4806.0

4.1.1 Demand Forecast

4.1.1.1 The Result of the Detailed Study on Demand in Damascus City

We carried out the microscopic study on the telephone demand in Damascus City, in which we studied the characteristic of service area of each telephone office, such as, the number of present subscribers, boundary, population growth in the area, and proportion of the demand of business subscriber to residential subscriber. Table 4.1.1.1-1 shows the proportion of the demand of business subscriber to residential subscriber.

Table 4.1.1.1-1 The Proportion of the Demand of the Business to the Residential

Category	<u> </u>	II	111
Subscriber's	Business user: 40%		
Ratio	Residential user: 60%	Residential user: 65%	Residential user: 70%
Telephone	Al Nasser	Bagdad	Mazzeh 1 & 2
Centers	Al Thawra	Jallaa	Kefr Souseh
		Al Mohajrin	Domar
1	·	, and the second se	Al Miedan
	[Al Yarmouk
			Rokn Al Dien
			Barzeh
			Bab Sharki
			New Tel. offices

Through these studies, we found the followings:

- Large demand is emerging toward the suburban area and it grows rapidly. The
 reason is that suburban area is turning into residential areas because of searcity of
 land and unavailability of buildings at the central area of the city.
- The existing telephone subscribers in suburban area are at present connected to the telephone offices located in city area near the suburban area.
- As a result, the boundary of the actual service areas becomes inadequate, and the number of subscribers connected to the existing telephone offices is becoming uneven in view of occupancy of capacity of telephone office.

In view of the above result, we concluded as follows:

 In order to satisfy the exploding new demand toward the year 2000, new telephone offices should be established, by dividing and reallocating the present service areas.

The reasons of the above conclusion are:

- Some large new demand is emerging far away from the location of the present offices. The telephone lines from new subscribers to the telephone office would be longer if a new telephone office at a suitable location is not established, which increases the investment expenditure for outside plant.
- At some telephone offices, the capacity is almost fully used and it cannot serve any more subscribers. If a new telephone office is established near the existing fully occupied telephone office, the new one will take the existing subscribers out from the existing one to reduce its burden. In this way, the existing one can serve new demand with the same capacity.

4.1.1.2 Demand Forecast of each Service Area

Following the conclusion of previous section, we planned the locations of new telephone offices and reallocated the boundary of areas, taking into account of subscriber density and size of the area, based on the forecasted demand in the year 2000. The demand of the year 2000 is allocated to each telephone office, including newly planned telephone offices. The result is shown in Table 4.1.1.2-1.

The table also shows the number of existing subscribers in 1995. Part of the present subscribers should be reallocated to the new telephone offices, and the numbers of present subscriber of the old telephone offices become reduced. The table shows the reallocation, too.

Table 4.1.1.2-1 The Demand Allocation to the New Telephone Offices

Telephone Office	Existing	Reallocation to	Demand
•	Subscribers in	new offices in	Forecast in
	1995	1995	2000
Al Nasser	39,580	35,600	49,300
(Al Thawra)		9,200	41,500
Kefr Souseh	8,937	8,900	41,500
Domar	8,662	8,700	34,500
Al Mohajrin	13,598	13,600	42,800

(Jobar)		4,200	41,500
Total	248,422	248,400	794,400

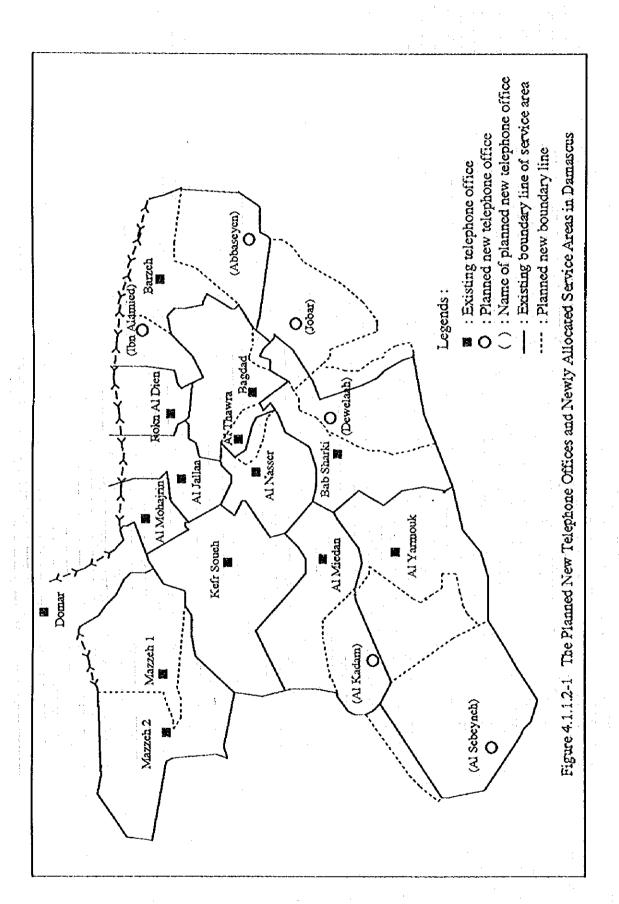

The telephone offices in parentheses () are new.

The telephone offices with boldface need new allocation.

Figure 4.1.1.2-1 shows the existing telephone offices, the planned new telephone offices, the present service areas, and the planned new boundary of the service areas.

On the basis of the result above, the demand of each telephone office was forecasted for each year, which is shown in Table 4.1.1.2-2.

The names in parentheses () are new telephone offices.

4.1.1.3 Demand forecast of Public Payphone

At present there are 304 public payphones in Damascus city, and the penetration ratio per 1,000 habitants is 0.2 phones. This figure is still low compared to the world average 0.7 according to ITU's "World Telecommunication Indicators" (94/95).

In the year 2000, it is estimated 850 phones are in service and the penetration ratio will exceed the world average in the year 2005.

Table 4.1.1.3-1 shows the result of the demand forecast of the public payphone in Damascus.

Table 4.1.1.3-1 The Demand Forecast of Public Payphones in Damascus

	1995	1996	1997	1998	1999	2000	2005
Forecasted Number of Inhabitants (000)	1,560	1,610	1,670	1,720	1,780	1,840	2,170
Forecasted Number of Payphone Lines	(304)		500				1,580
No. of Payphone Lines per 1,000 Inhabitants	0.20	0.25	0.30	0.36	0.41	0.46	0.73

The figure in parenthses () is the number of existing public payphones.

4.1.2 Fulfillment Plan

The fulfillment plan in Damascus city was made, taking into account of the Fulfillment plan made in the Action Plan, the latest existing subscribers, and STE's Eighth National Five-Year Plan, following the newly allocated figure of 1995 and the demand of 2000 in Table 4.1.2-1.

The result is shown in the Table 4.1.2-1. Although some new telephone offices are not established in 1996, the figure of them shows the obligation that the new offices should undertake. Accordingly, the numbers of the subscribers of present existing offices are lightened.

This fulfillment plan shows the number of subscribers that should be served in the corresponding year. Therefore, the telecommunication facilities, such as switching equipment and outside plant, should be implemented previously.

Table 4.1.2-1 The Fulfillment Plan of Damascus City

<Notes>

The names in parenthses () are the planned new telephone offices.

The plan is figured out on the presumption that new offices are established in 1996.

4.2 Traffic Forecast and Circuit Calculation

4.2.1 Traffic Forecast in Damascus Area

The traffic for local calls and long distance calls including international and mobile telephone calls is calculated based on the figures year 2002 of the fulfillment plan in the Action Plan, taking two(2) years provisioning time.

Damascus area is divided into three(3) areas, which are Damascus city, Damascus rural and Damascus region, and the new structures of the local and long distance networks are proposed as described in Chapter 3.

The calling rate per subscriber classified in business and residential subscriber on the basis of actual traffic trend as shown in Table 4.2.1-1. As a result of detailed study by each district and telephone offices, the ratio of business and residential subscribers by exchange office and the ratio of call kinds are categorized in four(4) parts in Damascus area as shown in Table 4.2.1-2 and Table 4.2.1-3.

The traffic matrices are calculated based on the above all factors and the gravity model methods. And the mobile telephone traffic from and to PSTN is added to the matrices as shown in Figure 4.2.1-1.

Table 4.2.1-1 Originating Calling Rate

Business user	0.065 erl. per subscriber
Residential user	0.040 erl. per subscriber

Table 4.2.1-2 Business and Residential Subscriber's Ratio

Γ	Category	,	1		2		3		4
r	Subscriber's	Business	Residential	Business	Residential	Business	Residential	Business	Residential

	: + **					in the yea	r 2000	year 2000	

Table 4.2.1-3. Traffic Distribution

Item 🐯	Category 1	Category 2,3	Category 4
Intra-office call	12%	13%	38%
Local call	76%	77%	56%
National call	8%	8%	5%
International call	4%	2%	1%

Note: The future traffic volume per subscriber is estimated at the following conditions;

- 1. The volume of originating traffic is approximately equal to terminating traffic.
- 2. The calling rate by the year 2002 will be the same as the following basic data.
- 3. The traffic flow of the international call is based on Figure 3.1.1-1.

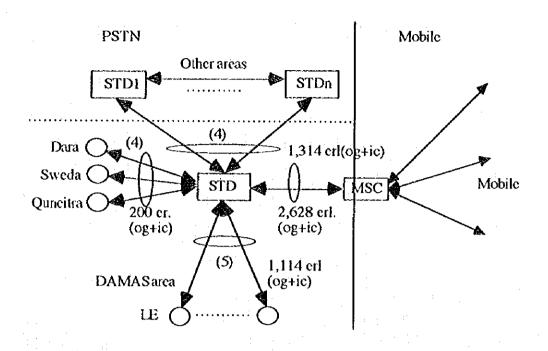

Figure 4.2.1-1 Mobile Telephone Traffic to and from PSTN

The outline of traffic matrix is shown in Table 4.2.1-4 and the details are shown in S3-2-4-1 to S3-2-4-8 in the Supporting Report.

The results of traffic calculation are shown in Table 4.2.1-5, Table 4.2.1-6 and Table 4.2.1-7.

4.2.2 Circuit Calculation in Damascus Area

The circuits between exchanges are calculated based on the traffic matrices, the proposed network structures and the routing plan as described in Chapter 3.

In addition, the following detailed conditions are considered for the calculation.

(1) Routing for each exchange stage is Table 4.2.2-1.

Table 4.2.2-1 Routing for Each Exchange Stage

Stage of exchange	Traffic distribution ratio	No. of routes
INTS	INTS(Damascus): 60%	2 INTSs in Syria
	INTS(Aleppo) : 40%	2 routes from/to each 6 STDs
STD	Al Nasser STD: 50%	2 STDs in Damascus
	Thawra new STD: 50%	2 routes from/to each INTS
		2 routes from/to each LE
		Mesh network between STDs
LE/LT(combined)	Umbrella LE : 50%	2 routes from/to 2 STDs
	Sub-Umbrella LE: 50%	2 routes from/to each LE under
		umbrella and sub-umbrella
		Mesh network between LE/LTs
LE	Home LE/LT : 50%	2 routes from/to 2 home LE/LTs
	Sub-Home LE/LT: 50%	
MS(Mobile Switch)	Al Nasser STD: 50% Thawra new STD: 50%	2 routes from/to 2 STDs

- (2) Both way circuits are applied to the calculation because of No.7 CCS between exchanges.
- (3) The connection loss probability per 1 link is 0.01.

The scope of circuit calculation in this project is as follows and shown in Figure 4.2.2-1:

- Long distance routes which are composed of international, long distance and mobile telephone calls.
- Local routes (high-usage and final) form/to LEs in Damascus city
- All routes including international and mobile telephone calls from/to STDs in Damaseus.

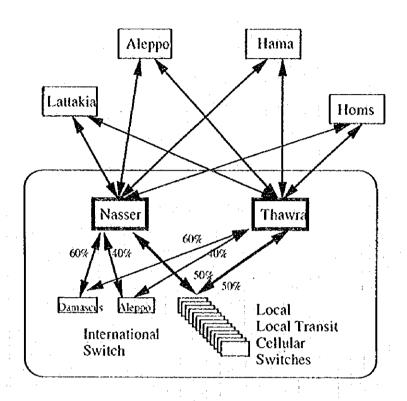

Figure 4.2.2-1 The Scope of Circuit Calculation

The calculation results are shown in Table 4.2.2-2, Table 4.2.2-3 and Table 4.2.2-4, and the details are shown in S3-2-4-9 to S3-2-4-14 in the Supporting Report.

4.3 Switching System

4.3.1 Exchange Facilities

4.3.1.1 Present State of Exchanges

(1) Local Exchange

There are eighteen (18) working exchanges in Damascus city at present, which are listed in Table 4.3.1.1-1. Ten (10) of them are EWSD exchanges which were recently established. EWSD is an advanced digital exchange that is capable of introducing new services, and has centralized operation and maintenance functions. The other eight (8) exchanges are older types composed of four (4) EMDs, two (2) E10As and two (2) NEAX61s. In particular, the EMDs are worn-out step-by-step exchanges that were established over twenty years ago, and have problems such as difficulty in the introduction of new services and shortages of spare parts. Thus, EMD exchanges urgently needed to be replaced with new digital exchanges.

Regarding the Local Network hierarchy, two types of exchanges have already been established. One is of only local exchange function, the other is a combined type that has local and transit exchange function. The actual number of line units of the local exchange is limited to about 30,000 lines from security points of view.

Local exchanges that furnish ISDN services (Basic access) have already been introduced to four (4) big cities (five local exchanges) and have approximately 450 line units, but there are no actual ISDN users at present. However STE has a plan to start ISDN services in near future.

Exchange	No. of ISDN basic access
Damascus G3	150
Damascus B1	100
Lattakia D1	50
Aleppo B2	100
Homs D1	50
Total	450

(2) Long Distance Transit Exchange (STD)

At present there is one (1) STD exchange at Al Nasser in Damascus city which has about 20,000 trunk circuits, 60% of which are working now. There is no established theory how to set up routes between STD and Local exchanges. In fact, twenty-five (25) local exchanges are connected to STD via direct routes and thirty-eight (38) local exchanges are connected via two (2) exchanges. Sixteen (16) out of thirty-eight (38) local exchanges in the Damascus area have a function for selecting the first route followed by the second route, the other twenty-two (22) local exchanges select two routes based on equal priority that are through two exchanges. As a result, planning, operation and maintenance is a little complicated.

(3) International Exchange (INTS)

At present there are two (2) INTSs, one in Damascus and one in Aleppo. International calls are connected to these INTSs via STD exchanges. However, the number of circuits between INTSs and STDs is not balanced. The Damascus INTS has about 10,000 trunk circuits, half of which are for STDs. The Damascus INTS is almost at full capacity, but the Aleppo INTS has room to expand circuits.

4.3.1.2 Facility Plan

- (1) Local Exchange
- (a) Basic Telephone

The expansion plan was decided in consideration of the following conditions.

- The number of line units for each local exchange was decided on basis of the fulfillment plan, taking into account a lead time of 2-years for provisioning i.e. employing the year 2002 fulfillment plan.
- Four (4) EMD exchanges shall be replaced with new digital exchanges by 2000.
- The actual maximum number of lines for an exchange are assumed to be 30,000 lines from security reason.
- The newest digital exchange with capability of new services such as ISDN, free call should be introduced.

Expansion, new establishment and replacement of exchanges in Damascus city are proposed based on the above all conditions as shown in Table 4.3.1.2-1.

Table 4.3.1.2-1 Proposed Number of Line Units

(b) ISDN (Integrated Services Digital Network)

ISDN services will be introduced mainly to the governmental organization, company and business users for the G4 facsimile, data communication and so on. The STE has ambitious demand forecast for ISDN that is assumed to be 1% to 2.5% (80,000 ISDN sub.) of basic telephone line units all over the Syrian country by the year 2002, however it is difficult to fix ISDN demand at initial stage because that demand is deeply related to introducing strategy (mainly advertisement and tariff). In this report, the Study Team assumes the ISDN demand by the year 2000 is 1% of basic telephone line units (5,000 ISDN sub.) within Damascus city. It is important to reconsider the ISDN demand with the progress of increasing users.

(2) Long Distance Transit Exchange (STD)

Considering increase of subscribers and telecommunications security, one new STD should be established at the Thwara building separated from the existing STD at Al Nasser building as described in Chapter 3. For security reason, two routes will be required between STD and local exchanges as shown in Figure 4.3.1.2.-1.

The total number of circuits between two Damascus STDs and other area's STDs / INTSs / MSC is shown in Table 4.3.1.2-2.

(3) International Exchange (INTS)

To solve the imbalance between two INTSs the traffic distribution ratio will be 60% for Damascus INTS and 40% for Aleppo INTS step by step as shown in Figure 4.3.1.2.-1.

The total number of circuits between two INTSs and two Damascus STDs is shown in Table 4.3.1.2-2.

Table 4.3.1.2-2 Summary of the Total Number of Circuits for Long Distance, MSC and International Calls in this Project

4.3.2 **Power Supply System**

4.3.2.1 Design Criteria

The power supply systems in the objective exchange offices are designed in consideration of the present conditions of the commercial power and the future plan of the telecommunications facilities to be introduced.

- **(1)** General
 - (a) Composition of Power Supply System
 - AC Mains(Receiving/Distribution of AC commercial power)
 - **Engine Generator**
 - UPS (Uninterruptible Power Supply) or INV(Invertor)
 - Rectifier
 - **Batteries**
 - (b) Lead time for provisioning

The power supply systems are designed to correspond to the following periods:

AC Mains

Capacity at the ultimate stage

(Capacity for the contract is to be the same

as that at the initial stage.)

Engine Generator:

Capacity at the ultimate stage

UPS/INV

Capacity at the ultimate stage

Rectifier

Capacity at the initial stage

Batteries

Capacity at the initial stage

Note: initial stage

year of service commencement (S + 0)

ultimate stage:

year at the final capacity

(2)AC Mains

The AC commercial power:

High tension: 20KV, 50Hz, 3-phase (PEE facility)

Low tension: AC 380V/220V, 50 Hz, 3-phase/1-phase (STE facility)

- (3) **Engine Generator**
 - Type of Engine Generator (a)
 - Diesel engine
 - Continuos operation type

Cooling type

Air-Radiator or Water-cooling type

Output

AC 380V/220V, 50 Hz, 3-phase/1-phase

(b) Capacity of Fuel Tank

Considering the condition of operation and maintenance, the fuel tank will be, in principle, capable of storing:

Main exchange offices/stations:

3 days(minimum)

Small exchange offices/stations:

4 to 10 days

(4) UPS/INV

In case of commercial power interruption, the engine generator requires a moment for start-up and stabilizing. Therefore, the UPS/INV should be provided to prevent power supply interruption.

Holding time

10 minutes

Input voltage

AC 380V/220V, 50 Hz, 3-phase/1-phase or DC -48V

Output voltage

AC 220 V, 50 Hz, 1-phase

(5) Rectifier

Most facilities and equipment work by providing DC power (DC-48V), so the following rectifier will be applied:

Input voltage

AC 380V/220V, 50 Hz, 3-phase/1-phase

Output voltage

DC-48 V

Туре

One stand-by (n+1), floating

(6) Batteries

In order to prevent a DC power supply interruption, sets of batteries will be provided. The back-up time of the batteries is established to be four(4) hours in consideration of the reliability of commercial power and the other power supply system.

- Back-up time

Four (4) hours

Output voltage

DC-48 V

Турс

Maintenance type for main exchange offices/stations

Maintenance free type for small exchange offices/stations

(7) Miscellaneous Equipment

As miscellaneous equipment, the following equipment will be provided:

- High tension facility (Line, transformer)
- MTR (Meter)

Low tension commercial power (AC 380V/220V, 50 Hz, 3-phase/1-phase) is lead in through the MTR.

- BRK (Breaker)
 - Low tension commercial power is connected with the BRK.
- MDP (Main Distribution Panel)

MDP divides the commercial power into two streams, one is to directly supply AC power to the load, another is to be connected with engine generators, UPS and rectifier/batteries.

- LBP (Low tension branch panel)
 - Low tension power is distributed to the various load through the LBPs.
- LTP (Low tension change-over panel)
 - LTP has a function of change-over from commercial power source to output of engine generator, vice versa.
- MTS (Mobile transfer switch)
 - MTS has a function of switch-over from internal power source such as commercial power or output of engine generator to external power source in case the internal power source fails.
 - MB (Mobile box)

The external power source is connected to the MB.

4.3.2.2 System Diagram

The power supply system at the exchange office is designed taking into account the accommodation plan of the telecommunications systems. The high tension facility is provided, owned and maintained by PEE (The Public Establishment for Electricity).

STE has to bear the full provisioning cost of it.

The typical system diagram of the powers supply system at the exchange offices is indicated in Figure 4.3.2.2-1.

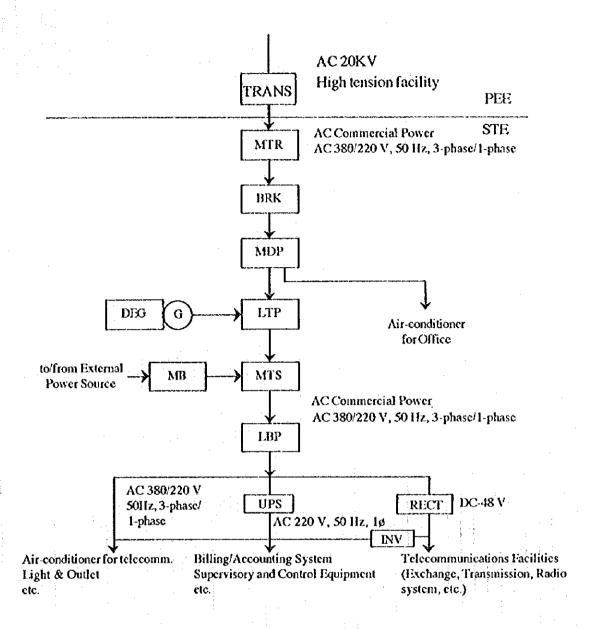

Figure 4.3.2.2-1 System Diagram of Power Supply System

4.3.2.3 Power Consumption

The power consumption at each exchange office is estimated based on expansion and new establishment sizes of exchanges as shown in Table 4.3.2.3-1.

Table 4.3.2.3-1 Power Consumption

4.4 Transmission System

4.4.1 Transmission Facilities

4.4.1.1 Present Status of Transmission

Under the Contract 40/A and 3/A, Damascus junction network was renovated with 140Mbps fiber-optic transmission systems. Recently, the network has been enhanced its circuit capacity by installing more 140Mbps systems under the 25% Expansion Contract 40A. The number of 140Mbps systems for each route (or section) in the network is summarized in Table 4.5.1.2-1.

The network configuration is similar to physical mesh network and somewhat complicated with many 140Mbit systems. The installation under the 25% Expansion Contract relieves capacity shortages. The drawback to the capacity increase is that it endangers network security to a certain extent by using up all fibers in some sections which could be stand-bys for failed fibers.

4.4.1.2 Result of Survey

A field survey has been carried out to determine obstacles to transmission facility plan execution. No major obstacles were found.

Since the transmission rooms in telephone offices B (Rokn Al Dien) and C (Bagdad), have little space for new equipment, the field survey shall be carried out by contractor.

The floor-to-ceiling height is more than 4 meters and is sufficient for any transmission equipment. The floor is strong enough for loading equipment, based on existing equipment.

4.4.1.3 Facility Plan

The facility plan takes the following into account;

- (1) The proposed logical mesh network at the center of Damascus (see Figure 3.1.3-3) must not complicate physical network much more.
- (2) The existing systems are new ones and should be utilized.
- (3) 50% circuits are secured even in the case of one route failure. (100% circuit protection is better from view point of security, but not economical. Since distances between two telephone offices are short in Damascus, route failure is rarely expected to happen.)

(4) One pair of spare fibers is maintained for as many sections as possible.

1

1

(5) According to the world technology trend, SDH transmission systems shall be introduced into the Damascus Junction Network as soon as possible.

The Master Plan proposes eight SDH rings (loops) in the network. Some of the eight loops are selected to satisfy the circuit demand in Damascus targeted area in the year 2002 (2000 + two years lead time). As Jobar become a Home LT in the plan as shown in Figure 3.1.3-3, the plan makes LOOP 9 as a SDH ring over Jobar, Dewelaah, Damascus C (Bagdad), and Damascus H1 (Bab Sharki). The other loops will be accomplished after the year 2000.

Based on the circuit calculation in Section 4.2.2, the number of circuits required for each section are summed and are shown in Figure 4.4.1.3-1. Circuits between STD1 and MSC (Mobile service switching center) are included, but long distance circuits from/ to STD1 and STD2 to/ from the other toll transit exchanges and INTSs are excluded. Circuits between MSC and each of BTSs(Base transceiver stations) are handled in Chapter 5.

Figure 4.4.1.3-1 illustrates sections where circuit shortages are anticipated in compare with existing numbers of circuits.

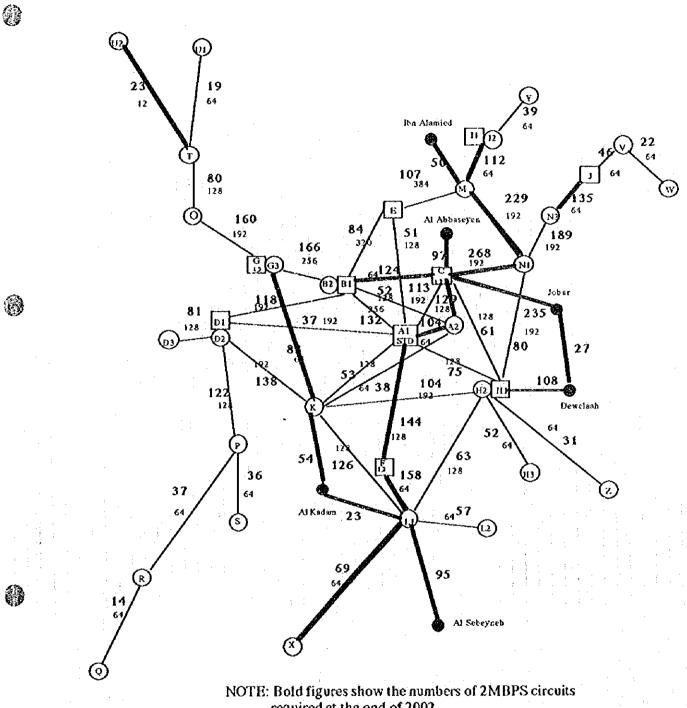

For the sections with circuit shortages, SDH rings, LOOP1, LOOP2, LOOP3, LOOP5, and LOOP9 are proposed as shown in Figure 4.4.1.3-2. Table 4.4.1.3-1 shows circuits related to each of the loops. The "CAPA" in the table means Loop Capacity required for SDH transmission systems in each of the loops. For the 50% circuit protection, the half of the "CAPA" is required as loop capacity. (For 100% circuit protection, full "CAPA" is required.) Therefore, SDH-4 systems are justified for each of the loops.

The section between Damascus K (Kefr Sousch) and Damascus G (Al Mohajirin) has a circuit shortage, but no new facility is planned there, because re-routing of circuits can solve the shortage.

Removed 140Mbps systems must be transferred to sections related to new telephone offices, Ibn Alamied, Al Abbaseyen, and Al Sebeyneh, where also new optical fiber cables are required.

The usage of SDH-4 systems easily enable spare fibers to remain, as the SDH-4 systems have larger capacities.

Concept designs are made for the loops as shown in Figure 4.4.1.3-3, based on required circuits on Table 4.4.1.3-1. Estimates of power, space and cost required for the transmission facility have used the concept designs.

NOTE: Bold figures show the numbers of 2MBPS circuit required at the end of 2002.

Small figures show existing section capacities in 2MBPS.

: Sections with circuit shortage

4.4.2 Power Supply System

Power required for the transmission facility in Section 4.4.1 is estimated from the concept designs of SDH systems as shown in Table 4.4.2-1. There is no standard power consumption for each equipment, so Table 4.4.2-1 only shows orders of power consumption.

Table 4.4.2-1 Estimated Power Consumption

Note*: applied existing Al Thawara power consumption

Since no power supply facilities are exclusively used for transmission equipment in the Damascus targeted area, power required for transmission is covered by the Power Supply System for Switching system in Section 4.3.2.
