Chapter 7 Energy Demand and Supply Forecast

Chapter 7 Energy Demand and Supply Forecast Model

7.1 Development of Energy Demand Forecast Model

7.1.1 Structure of Model

Following considerations' have been undertaken during the systemization process of this energy demand forecast model.

- (1) To make the total system easy operation.
- (2) To simplify systems transfer and inheritance, maintenance/enhancement and expansion work should be within the level of ordinary personal computers operations.
- (3) Easy to maintain the system for data correction and updating.

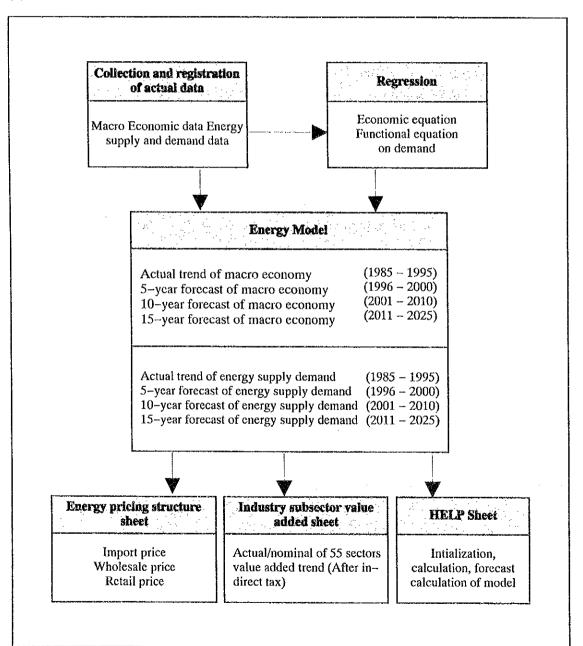

Major part of this energy demand forecast model is comprised from model portion which structures master file, however, also it is divided into sub-models for further research and experiment. Whole data are scparated into 6 files which include 400 affiliated yearly data. Number of equations comprise from total 300 including 100 in macro economy data and model, and 200 in model itself respectively. Actual data (10 years data from 1985 to 1995) which are stored in the master file are based on the statistical data obtained from the Central Statistics Office (CSO). CSO is normally updating these data three to four times a year. Programs for operating these data are established to maintain whole systems without influencing re-programming effort on the whole structure of the model and equation/regression formula during each process of data correction and updating.

This model is also able to subdivide into macro economy model and energy model, and has flexible simulation function by responding to given preconditions. Information related to financial sector is very important for analysis energy demand, however, it has been limited to the minimum requirement since financial information itself has wider structure. So that growth of economic sector are reflected to the model because it responds greater to energy demand. When forecasting energy demand, simple method of calculation by taking GDP growth rate is very common, however, it is very important to clarify economic growth of each sector because price elasticity of industry sector varies sector by sector.

Also energy demand will be influenced by price, its price affiliation are considered in the model.

3

Energy demand forecast model in this project comprises from macro economic forecast portion and from energy demand forecast portion. Overall structure and its each portion are shown in the chart below.

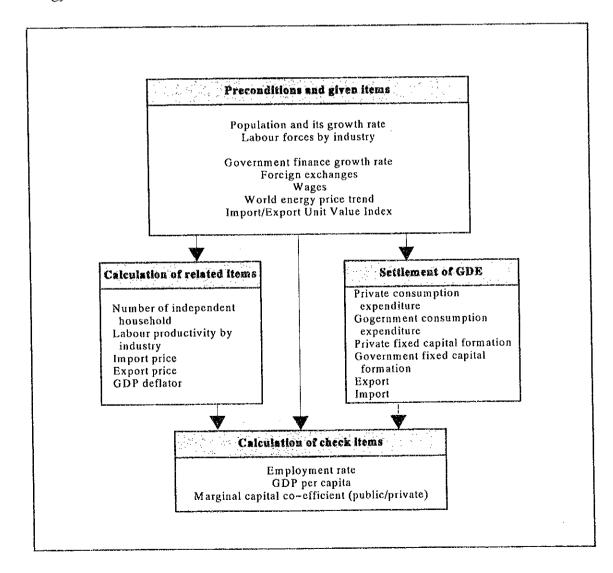

(1) Overall flow of model

As a whole, the model has been stored in a file (or a BOOK: one screen in the computer which is consisting from multiple sub-screens) of Microsoft's Excel, a software package for spreadsheet, and being created in each sheet by dividing into sub-models including energy pricing structure, value added data of industrial subsector and HELP sheet.

(2) Macro Economic Frame

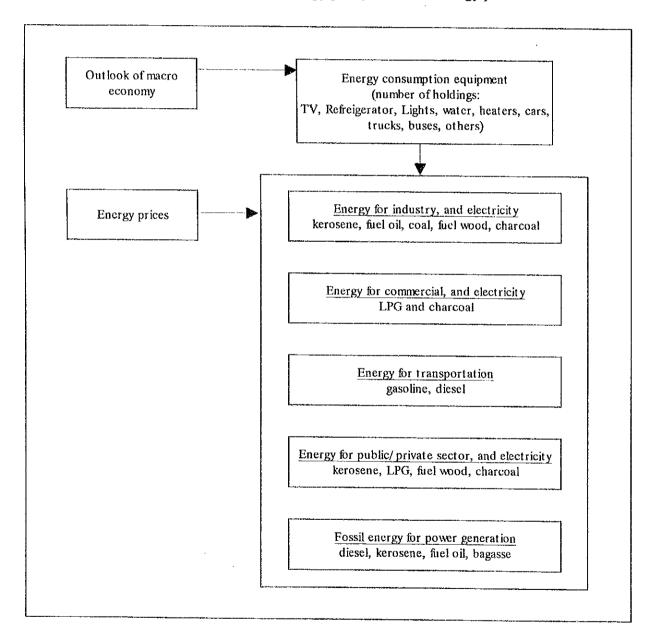

Structure of macro economic frame is shown below. Since final objectives of this model is to forecast on demand of energy, macro economic forecast portion has been kept to a minimum frame for extraction and confirmation of internal/external variables for the use of energy demand forecast.

Stores.

(3) Frame of Energy Demand Forecast

Structure of energy demand forecast frame is shown below. Final objectives in this frame are to calculate demand perspectives of fossil energy (gasoline, diesel, kerosene, fuel oil), bagasse and electricity, however, the structure of this demand forecast is also able to analyze influences to macro economy and energy policy as well as energy prices.

Ŵ

7.1.2 Structure of Databases

Energy database systems in this project comprises from the following components;

- Computer hardware systems
- Computer software
- Energy database

Establishment of energy database systems has been done by undertaking the process as follows:

- (1) Review of available information through statistic data books, documents, and other related material obtained from the Central Statistical Office
- (2) Encoding, correction, updating, matching, and revision of above obtained information and data
- (3) Review of hardware and software: Price and functional comparison on hardware and software by obtaining estimates from several personal computer dealers and decided computer systems and peripherals including software to purchase
- (4) Purchase and installation of the total systems
- (5) Systems development
- (6) Documentation of operation manual

In addition, following development environment including installation of hardware systems, software, and systems development has been established.

(1) Development of Installation Environment of Hardware and Software

System A (Master system): Personal computer (IBM compatible, one unit System B (Backup system): Personal computer (IBM compatible, one unit Basic software: MS-Windows environment

Application software:

Spread sheet software for creation of database

Word processing software for documentation

Relational database software for future expansion

記

-

Computer language software for development

(2) Organization and structure of files

The datafiles established in the computer are stored in the hard disk (main drive: drive c), so that users are able to retrieve by accessing into these files.

(3) Systems Linkage Test

All systems tests, including hardware and software, network tests such as physical and logical connection test, setting test of UPS and printers are completed. Systems linkage test for each systems and total systems are also completed.

(4) Development of interface program

Tasks such as transferring existing encoded data to the new system and development of interface program between such data and user/operator are already completed. All these tasks were developed by using Visual Basic which is a computer language development software.

(5) Setting of Documentation Work

Setting of environment for documentation including operation manuals, systems maintenance and management, and program sheet for energy database systems are also complete. These documents are created in MS-WORD which is commonly used general purpose word processing software.

Computer Hardware Systems

Following preconditions were set prior to the selection of computer hardware systems.

- 1) To select general purpose use of computer hardware
- 2) To establish database in easy-to-transfer formation systems
- 3) To support and manage without any extra effort

Database system is comprised from the following computer hardware.

Unit 1

| Personal Computer | |
|---------------------------------|-------------------|
| Central Processing Unit: | AcerMate 800 |
| Display monitor: | AcerView 33D SVGA |
| Printer: | LexMark Optra R |
| Un-hazardous Power Supply(UPS): | Ares |

Unit 2

| Personal Computer | |
|---------------------------------|-------------------|
| Central Processing Unit: | AcerMate 920 |
| Display monitor: | AcerView 33D SVGA |
| Printer: | LexMark Optra R |
| Un-hazardous Power Supply(UPS): | Ares |

Among these systems, Unit 1 is assigned as a master computer and used as the exclusive system for a database establishment and interface development work. Unit 2 is assigned as a backup system for Unit 1 and has not only backup capability but functions as a simultaneous use during the operation of Unit 1 by physical connection using EtherNet cables and Peer to Peer logical connection structure.

Two sets of UPSs are adopted as an independent connection structure method in each Unit of the computers, so that the whole system including hardware, software and stored files can be protected and maintained for 5 minutes in case of power failure.

Computer Software

Following pre-conditions are set prior to the selection of software.

- (1) To choose general purpose use of application software packages
- (2) To establish energy database in easy-to-transfer software
- (3) To support and manage without any extra effort of ordinary software operation

Following software have been selected for computer operation and for establishment of energy database systems, and settled total system operable conjunction with aforementioned computer units. These software have been installed in two computer hardware units (Unit 1 and Unit 2) and operable simultaneously.

Basic software and emulatorMS-Windows 95 Application softwareMS-OFFICE PROFESSIONAL Integrated software package including below;

MS-EXCEL for Windows : Software for spread sheet
MS-WORD for Windows : Software for word processing
MS-ACCESS for Windows : Software for relational database management
MS-Visual Basic ProfessionalVersion 4.0 : Software for program development
Statistical Software : Custom-made of software by adding calculation function of Darbin-Watson to regression analysis function of Excel, and works as an add-in software to Excel.

To establish energy database, MS-Excel is used as an application software package for creation of master file by the following reasons;

- (1) Run on series of Windows operating systems environment, which has become a de facto standard among all personal computer market.
- (2) Has function of general purpose use and should be the software which is familiar to those who inherit the system.
- (3) Should have powerful functions of which not only for arithmetical operations

19.44

function but can be used as a tool of complicated database analytic tools including regressions with simple operation.

(4) Has superiority on Graphic User Interface (GUI) applications, so that the systems developers and operators are easily able to create and access graphics tools for further data analysis.

Energy Database

(1) Contents of Database

Major portion of information in the energy data base systems are consisting from of the following main categories. These are classified into sub-categories and stored as databases in the computer. Those details classified sub-categories are omitted from the list in this Chapter because they can be referred by looking at actual computer files.

Macro Economic Data

- 1) Population including labour force
- 2) Gross Domestic Product: GDP (Current and constant price)
- 3) GDP deflator
- 4) Labour productivity
- 5) Wage at current price
- 6) Government finance (Current and constant price)
- 7) Consumer price index and exchange rate
- 8) GDE at current and constant price
- 9) Macro economic index

Energy Demand Data

- 1) Energy conversion factors
- 2) World energy price trend
- 3) Energy wholesale price (Physical & TOE)
- 4) Energy retail price (Physical & TOE)
- 5) Electricity price (Physical and TOE)
- 6) Transportation equipment
- 7) Energy consumption(Physical & TOE) by:

7 - 9

- 7)-1 Industry
- 7)-2 Commercial
- 7)-3 Transportation
- 7)-4 Domestic home appliances

Energy Supply Data

- 1) Electricity supply
- 2) Electricity generation by sources
- 3) Generation efficiency by sources
- 4) Fuel input for electricity generation (Physical and TOE)
- 5) Energy supply (Physical and TOE)
- 6) Energy for re-export
- 7) Bagasse supply and consumption (Physical and TOE)
- (2) Structure of Database Files

Figure 7.1.1 shows the hierarchical structure of database files and size of file area for installed software and energy data. And Figure 7.1.2 shows file structure of the database. Detailed structure of installed database are already shown in 7.1.1 of this Chapter. So that to avoid overlapping of those, only structured file name and overall contents of installed data which are shown from operation side of the system are listed below.

7.1.3 Renewal and Expandability of Databases

(1) Update of master file

The macro-economic frame and energy demand forecast model that are built in the Excel permit updating and expanding existing data easily. This is made possible by the Excel's basic functions. There is no need to use any special commands or development of extra database operating functions. In addition, by modifying or updating the master file (EnergyCase01 and EnergyCase02), it is possible to automatically update all the files which constitute databases. Process of updating the master file is described below.

To modify the 1985-1995 result data on the first sheet (Energy Model) contained in the master file (filename: EnergyCase01.XLS and EnergyCase02.XLS), input the new figures directly to the associated cell. To input data for the next year, first delete the cell and line in which data for the first year of analysis (in the case of the present database, the year 1985) has been input, then insert a new cell for input of new data after the cell in which data for the last year of analysis (in the case of the present database, the year 1985) has been input.

(2) Renewal of regression analysis file

To modify the 1985-1995 result data on the first sheet (ENG) contained in the regression analysis file (filename: REGM.XLS and REGE.XLS), input the new figures directly to the associated cell, and the other sheets are automatically modified together with the ENG sheet. Subsequent regression analyses can be performed by manipulating the Excel's regression analysis macro.

(3) Expansion of Database

.

The databases can be expanded either by using the Excel's function or by downloading the data in the Excel to the MS-Access--software for relational database (RDB)--to make the data an RDB. Since the macro economy and energy database were to be stored in the Excel at the early stages of the present survey project, the expansion by the MS-Access shall not

be effected during the project execution. However, in order to enable Mauritius side to use the MS-Access for expansion of databases in the future, the software has been loaded into the personal computers.

If Mauritius side wants to study the expandability of databases using the Excel functions, it is possible, for example, to add statistical analysis using the Excel's function command and automatic calculation and analysis of original data using the Excel's macro, though these functions depend upon the items and functions to be expanded. In addition, by incorporating the Visual Basic in the Excel, it is possible to provide additional macro functions and thereby enhance the analytical function.

7.2 Main Assumptions for Long-term Energy Demand Forecast

7.2.1 Case Scenario

(1) Base Case

Economic Assumptions

- 1) The sugar sector stagnates its development beyond 2000.
- It takes EPZ's restructuring for two decades up to 2010 and revitalizes again since then.
- 3) New businesses of free port and offshore banking, and established tourism grow steadily.
- 4) Actual working hours are extended by 6 hours a weak during 2010 and 2025.
- 5) Wage increases by 5% a year.
- 6) Taking into consideration that industrial goods' prices in the developed countries increases 2.2-2.3% a year, inflation in the Republic of South Africa for an indicator of Mauritius import price is 10% a year, by 3% less than past 10 years.
- Exchange rate of Mauricia rupees and South Africa's Rand is depreciated by 2% a year against US dollar.
- 8) Budget revenue and expenditure are neutral to the economy, which means that the component ratios of them and its deficit over the GDP do not change.

Energy Assumptions

- 1) Current crude oil price and coal price in a world market increase 3% and 1.8% respectively until 2010; 4% and 2.4% beyond 2010.
- 2) Taxes on imported energy sources do not change.
- 3) Electricity tariff is adjusted by price changes of local fuel and coal.
- 4) Energy conservation is materialized in industry, transportation and domestic sectors.
- 5) Current tendency of electricity shift of energy sources continues in each sector.
- Load factor in the power generation improves to 63.0% since 2006 from 57.0% in 1995. Loss ratio in the generators and power transmission improves to 13.0% since 2010 from 15.4% in 1995.

(2) High Case

- Economic growth will be higher owing to shorter period for EPZ' restructuring, considerable success of free port & offshore services, tourism boom and rapid increase of foreign workers.
- 2) Inflation in the Republic of South Africa increases by 13% a year due to revived world inflation.
- 3) Wage increases by 6% a year.
- Current crude oil price and coal price in a world market increase 2%, 1.2% up to 2010, and increase 3% and 1.8% respectively beyond 2010.
- 5) Energy conservation is not materialized in each sector.
- 6) Electricity shift of energy sources is accelerated in each sector excluding transportation.
- (3) Low Case
 - 1) Economic growth is lower due to fruitless restructuring of EPZ, poor activities of free port & offshore services and slow-down of tourism.
 - 2) Inflation in the Republic of South Africa increases by 7% a year owing to lower world inflation.
 - 3) Wage increases by 4% a year.
 - 4) Actual working hours do not change.
 - 5) Due to a low profitability of oil businesses, crude oil price and coal price in a world market increases 4% and 2.4% a year respectively until 2010; 5% and 3.0% a year beyond 2010.
 - 6) Electricity tariff increases by 30% equivalent of inflation adding to normal adjustment.
 - 7) Energy conservation is accelerated in industry and transportation sectors.
- (4) Other Cases

Many variations can be conceivable by different assumptions and their combinations. Some simulations were executed at the workshop during the third staying in Mauritius.

7.2.2 Back-ground Explanation of Main Exogenous Valuables in Each Case

- (1) Sectoral Output
 - 1) According to the "Prospects of Sectoral Development" in Appendix 3, sectoral growth of output is assumed as follows, up to 2025.

| | | | | | (%) |
|--|-----------|-----------|-----------|-----------|-----------|
| GDP at Constant Price (1990) | 1995/1985 | 2000/1995 | 2010/2000 | 2025/2010 | 2025/1995 |
| Agriculture, Hunting, Forestry, Mining, and | -0.1 | 4.0 | 1.0 | 1.0 | 1.5 |
| Quarrying | | | | | |
| Manufacturing | 8.1 | 5.2 | 5.5 | 7.8 | 6.6 |
| Sugar | -1.7 | 4.0 | 0.0 | 0.0 | 0.7 |
| EPZ | 10.4 | 5.0 | 5.5 | 8.0 | 6.7 |
| Domestic Manufacturing | 8.1 | 5.5 | 6.0 | 8.0 | 6.9 |
| Electricity, Gas, and Water | 6.7 | 8.0 | 8.0 | 8.0 | 8.0 |
| Construction | 9.0 | 5.0 | 5.0 | 5.0 | 5.0 |
| Wholesale, Retail, Restaurants, and Hotels | 8.5 | 6.5 | 6.0 | 5.0 | 5.6 |
| Transportation, Storage, and | 7.6 | 6.5 | 6.5 | 6.0 | 6.2 |
| Communication | | | | | |
| Banking, Insurance, Real Estate, Business service | 7.0 | 6.5 | 6.5 | 6.0 | 6.2 |

Table 7.2.1 GDP Growth Rate by Sector (Base Case)

2) First five years in 1995 - 2000, are the same assumption in each cases. Beyond 2000, two elements are setted in high case and low case. Labour productivity will increase by 10 % in a higher case and decrease by 10% in a low case in the two sectors of EPZ and domestic manufacturing and construction. Output of electricity, gas and water sector is also adjusted by the GDP in high case and low case.

(2) Labour Input

1) Labour Activity Rate and Foreign Workers

Mauritius falls into labour shortage owing to steady increase of jobs in the service sector, although labour is decreasing in EPZ. The unemployment ratio is extremely low at 1.7% in 1995. The population will increase only by 1% a year from now on. They need the capital intensive investment, but it is restricted by financial capacity. Mauritius labour cost is still comparatively low excluding EPZ. Labour supply is the most fundamental conditions for the future development.

The first remarkable change of labour supply is rapid increase of female activity rate from 25.9% in 1983 to 41.0% in 1995. The Central Statistical Office (CSO) estimates 48.0% of its activity rate in 2010 which is 7% point higher during 15 years since 1995 to 2010 compared with 11% point in the past 15 years. On the other hand the male activity rate is already saturated at 76-77%. As 48.0% of female activity rate is quite high, its rate will relax the increase tempo further: 3.5% higher during next 15 years since 2010 to 2025. Increase rate of labour forces cannot help slowing down from now on due to two factors; slower growth of population and slower increase of female activity rate. Labour forces will increase 1.5% a year in 1995-2000, 1.4% in 2000-2010 and 0.7% in 2010-2025.

The second is foreign workers, who have increased in a scare field of skills and know-how, mainly in manufacturing and construction. Foreigners are working also in a trade or service sector. They need foreign workers for restructuring of EPZ, construction for infrastructure, new business activities relating to free port and offshore services, or for management function in many sectors. Foreign workers will increase by one thousand a year from now on.

The second secon

Table 7.2.3 FOREIGN WORKERS

Source: Central Statistical Office

2) Working Hours

Working hours are regulated at 33 $\frac{1}{4}$ \sim 40 hours a week in the public sector by the recommendation of the Pay Research Bureau, while 45 hours average in the private

sector by the National Remuneration Board. If employers want employees work more longer, they have to pay 50% more the regular hourly wage in week days, 100% more for the first eight hours on holiday and 200 % more for afterward on holiday. This punishable overtime charge is popular in Europe from the view point of their graceful lifestyle and pragmatic safety network of work sharing against higher unemployment. But it is a prohibitive additional cost for employers to use them. Most of the Maurice labours go back punctually to take care for their family. As such a lifestyle is so popular, most of the shops and restaurants in Port Louice close during 4:00 and 5:00 pm. The buses, only public transportation except costly taxis also stop operation after six o'clock.

Such practices will be changed near future. US\$ 3,000 per capita and continuous inflation motivate the people to earn more by work rather than to enjoy plenty of time at home. This tendency will be stimulated by increase of foreign workers who work more longer. Mass transit system between Port Louice and Cuirpipe will benefit labours to go back late. These factors will push to amend the current employment regulation to reduce the over-time charge. If they decreases this 50% to 20% or 30%, which encourage employers to use their employees more longer for their profitable activities.

At the base case, working hours are assumed to extend by 6 hours a week during 2010 and 2025. In this assumption, local employees work roughly one hour more a week in 2025, which will contribute to increase labour input by 1% a year since 2010 to 2025. Otherwise, Maurice economy will suffer from stagflation with continuous wage push inflation and low economic growth, or from rapid increase of foreign workers.

3) Labour Input Assumption

Sectoral labour input is assumed as follows referring to the actual results and sectoral development analysis in Appendix 1.

| (Base Case, Annual increase rate 6 | | | | | | |
|--|---------|---------|-------------|-----------|-----------|--|
| | Ac | tual | Assumptions | | | |
| | 1985/90 | 1990/95 | 1995/2000 | 2000/2010 | 2010/2015 | |
| Agriculture, fishery, mining | -4.8 | -0.5 | -3.0 | -4.0 | -2.0 | |
| Manufacturing | 15.9 | 0.6 | -1.2 | -2.0 | 1.2 | |
| Sugar | -0.8 | -3.7 | -4.0 | 2.1 | -4.0 | |
| EPZ | 15.7 | -1.8 | -3.5 | }-2.0 | }1.3 | |
| Others | 21.8 | 5.7 | 2.0 | | | |
| Electricity, gas and water | -2.7 | 0.6 | -1.0 | -1.0 | -1.0 | |
| Construction | 19.2 | 3.0 | 3.0 | 3.0 | 3.0 | |
| Wholesale, retail, restaurant & hotels | 12.9 | 8.9 | 7.0 | 5.0 | 1.3 | |
| Transportation, storage & communication | 8.6 | 5.0 | 6.0 | 4.5 | 1.2 | |
| Banking, insurance, real estate, & business services | 13.2 | 6.8 | 5.0 | 4.0 | 3.0 | |
| Government and other services | 2.0 | 4.6 | 2.0 | 1.0 | 1.0 | |
| Total Labour Forces | 6.4 | 2.9 | 1.8 | 1.5 | 1.3 | |

Table 7.2.4 SECTORAL LABOUR INPUT

Note: Labour input is extended labour numbers adjusted by current working hours since 2010.

In the high case, foreign labours increase by one thousand a year more than the base case since 2001. In the low case, those decrease by one thousand a year less than the base case since 2001. Foreign labours work 20 hours more a week. This is equivalent to 1.5 times current local workers. Real effect to the labour input becomes one thousand five hundred labours a year on the current local labour base. Foreign labours are allocated mainly into manufacturing and construction, however there are some sectors where foreign labours works.

3⁴.3

| | | | (200 | 1-2025, Thousand) |
|--|------|-------------------|--------------------------------------|-------------------|

| business services | 0.2 | 2.0 | 0.1 | 0.1 |
| Total | 9.8 | 100.0 | 1.5 | 1.5 |

Table 7.2.5 SECTORAL CHANGE OF LABOUR INPUT VOLUME

4) Structure of Employment

According to the above assumption, the employment structure will change dramatically. Component of agriculture will drop sharply, which in 2025 is nearly the current level in the developed country. That of manufacturing in 2025 will be roughly a half of 1990. Construction will establish its own importance. Employees in the physical production will fall into 34.0% in 2025 from 49.4% in 1995, though the value added is still considerable owing to their high productivity.

On the contrary, service sector will swell. Wholesale, retail, restaurants and hotels will become the main sector in Mauritius owing to free port and tourism. This sector is still labour intensive with low-tech jobs. Transportation, storage and communication will grow rapidly, but this sector with wholesale, retail, restaurants & hotels may face restructuring after 2010. Banking, insurance, real estate and business services will grow steadly, but it will still stay at a small component due to high productivity by advanced communication technology. Government and other services will reduce their weight due to restructuring of the public sector, though personal and education services will grow steadily. Service sector will occupy 66.0% of the total employment in 2025 from 50.6% in 1995. The problem is how to bring up young generation for potential jobs under such a drastic change of market needs.

| | | | | | (Base | : Case, %) |
|-----------------------------------|--------|-------|-------|------------|-------|------------|
| | Actual | | | Assumption | | |
| | 1985 | 1990 | 1995 | 2000 | 2010 | 2025 |

| | 327 | 446 | 515 | 564 | 654 | 697 |
| Total number (thou.) | | | | | | |

Table 7.2.6 SECTORAL COMPONENT RATIO OF EMPLOYMENT

5) Labour Market

Two problems will appear in the labour market. One is the balance of the foreign workers and local labours. The component ratio of foreign workers will be three times from 1.9% in 1995 to 5.3% in 2025. 5.3% itself is not so large, but attention should be paid to job contents. The other problem is unemployment rate, which is easily changeable by job offered, because unemployees are the small margin between labour forces and employed workers. This unemployment rate is not so important in the long-term forecast. Main problem will be miss-match between labours and job offered. If they lack in adequate reform of education system & curriculum, and job training & retraining, this miss-match problem will be serious in the challenging future to cause increase of local unemployees under a considerable increase of foreign workers.

| | | | | | (Base Case) | | | |
|------------------------------------|------|------|------|------------|-------------|--|--|--|
| Labour Market | Ac | tual | | Assumption | | | | |
| | 1990 | 1995 | 2000 | 2010 | 2025 | | | |
| Local labour forces (thou.) | | | 565 | 648 | 721 | | | |

Table 7.2.7 LABOUR MARKET

(2) Inflation in the World

There is an important forecast of commodities up to 2005 by the World Bank. They use the unit value index in US dollar terms of manufactures exported from the Group 5 countries, that is France, Germany, Japan, UK and USA, weighted proportionally to the countries' exports to the developing countries. The World Bank forecasts comparatively low inflation in the developed countries in the coming 10 years, 2.3% in 1995-2000 and 2.2% in 2000-2005.

Table 7.2.8 G5 INFLATION

| | (# | Annual increase rate, %) |
|--|-------------------------------|--------------------------|
| i an | Export prices of manufactures | US GDP deflator |
| 1980-1985 | 1.0 | 5.4 |
| 1986-1990 | 7.8 | 3.6 |
| 1991-1995 | 2.9 | 2.8 |
| 1996-2000 | 2.3 | 2.7 |
| 2001-2005 | 2.2 | 3.2 |

Source: World Bank "Commodity Market and the Developing Countries" (August 1996)

This model uses consumer price in the Republic of South Africa, main trading partner for Mauritius. Her per capita GDP in 1993 is US\$ 2,980, nearly the same level of Mauritius.

60

.

Her GDP in 1993 is US bill. \$ 105.6, which is roughly four times total GDP of SADC nine countries. Though she is an economic giant in the eastern and southern Africa, there is still instability in the economic development due to a serious social & political problem on racial discrimination. New cabinet led by President Mandera was so welcomed in the world, that US bill \$6 has flowed into South Africa, a hopeful emerging economy since May 1994, however the National Party left the coalition cabinet in June 1996. Due to such an incompatibility, her currency has been devalued by 20 percent in 1996, which will aggravate her inflation. Though above uncertainties will exist in the future, we'll use the forecast of The University of Wastern Cape for the assumption.

| | (| Annual increase rate, %) |
|---------------------------------------|-------------|--------------------------|
| | 1993-1998 | 1999-2004 |
| GDP | 3.3 | 4.5 |

| 10% | 7% | 13% |

(3) Energy Price

There are two credible forecasts for energy price in the future. The World Bank provides

price forecasts of many commodities, whose figures are reflecting recent movements, but they are easily changeable. According to the latest publication, energy prices will increase by 1-2% a year, but they will decline in a 1990 price.

| | | | Actual | | | | Projections | | | | Annual increase |

Table 7.2.11 ENERGY PRICE FORECAST BY THE WORLD BANK

Source: The World Bank "Commodity Markets and the Developing Countries" (August 1996)

International Energy Agency (IEA), established in November 1974 in the OECD works for international energy plan. IEA published "World Energy Outlook 1993 in 2010" in 1993. They revised it and published "World Energy Outlook 1994 in 2010" in October 1995. Before they forecast energy demand and prices, they assumed the world economic development. Economic growth in the developing countries will be enhanced by 1.5 times than the past 20 years, while that in OECD will slow down. Population growth will decrease considerably in the developing countries as well as OECD.

| and a second | GI | OP | Population (annu | al increase rate %) |

World energy demand will increase moderately in 1991-2000 by 1.7% a year, but will

金藤

enhance increase rate to 2.4% in 2000-2010. Cheaper energy sources of natural gas and coal will increase higher than petroleum. Petroleum's share of total primary energy will fall steadily at 37.2% in 2010 from 39.2% in 1991, 47.8% in 1971. Per capita energy consumption will increase, though energy intensity will improve steadily.

| | | | | | | (Primary | energy) | |

Table 7.2.13 WORLD ENERGY DEMAND FORECASTS BY IEA

Source: IEA "World Energy Outlook 1994" (October 1995)

.

Electricity demand will grow faster than the total energy consumption but this difference will become smaller in the future. Coal, natural gas and hydro will occupies the main energy sources for power 79.0% in 2010, which used to be 70.4% in 1971, while petroleum's share will fall to 6.9% in 2010 from 11.4% in 1991, 20.7% in 1971. Costly petroleum already gave way to nuclear power in the electricity.

Table 7.2.14 WORLD ELECTRICITY FORECAST BY IEA

Source: IEA "World Energy Outlook 1994" (October 1995)

IEA assume the energy price more positive than the World Bank, but the energy price forecasted will stay at the same level after 2005. Coal price will also go up, but the increase rate will be than petroleum. In a short-term crude oil price jumped by 6% in 1996 due to Iraqi political tension and low level of inventories, however energy price will be stable in the long run owing to increase of non-OPEC oil supply by new technology or potential development of oil, and policy change of OPEC countries to own export volume rather than price stability of crude oil. However there are still many uncertainties in the oil price, because OPEC's share of oil production is 35.7% in 1995, still considerably high and FSU's energy policy does not clear yet.

As a result, we assumes the energy prices as follows in this model.

Table 7.2.19 ENERGY PRICE ASSUMPTION

| | | | | (current p | rice, annual inc | crease rate %) | |
|---|-----------|-----------|---------------------|------------|------------------|----------------|--|
| بالا 10 مليد المحمد الخليب وورو مع م لي ال | Base Case | | High | Case | Low | Case | |

| Coal | 1.8 | 2.4 | 1.2 | 1.8 | 2.4 | 3.0 | |

(4) Energy Conservation

Assumption of energy conservation for base case comes from the analysis in 8.4. High case is assumed no improvement in each sector. Low case is assumed the same improvement in OECD countries in industry, and 1.5 times improvement in transportation.

| | | (1996-2025, annua | al improvement rate %) |

| Transportation | 0.46 | 0.00 | 0.69 |
| Domestic | 0.33 | 0.00 | 0.33 |

Table 7.2.20 ASSUMPTION OF ENERGY INTENSITY

(5) Load Factor & Loss Ratio in the Power

Load factor is an actual power generation ratio over the peak power production. The electricity demand is fluctuated so much at each hour and the power company shall have the sufficient generation facilities to meet the peak load. If the power consumption is almost flat whole the day, the power company can provide power with a smallest facility. However the company has to equip redundant facilities, if the consumption curve is largely fluctuated.

Loss ratio is an ratio of electricity difference between the power generation and payable consumption over the sold electricity. This loss is composed of generator's self consumption, transmission & distribution loss and stolen electricity from their network. Stolen electricity is very small in Mauritius less than 1%. Main loss factor is the smaller voltage transmission lines and self consumption of generators. They need investment to efficient generators and transmission & distribution system to improve this loss ratio.

Above load factor and loss ratio are assumed as follows in any cases of this forecast.

| | Load Factor | Loss Ratio |
|---------------|--------------------------------|------------|
| 1996 | 60.0 | 15.2 |
| 1997 | 60.3 | 15.5 |

7.3 Outcomes of Economic and Energy Demand Forecast up to the Year 2025

Table 7.3.1 shows that expected average growth rates of each economic sector from 1985 to 2025 are depicted according to the three scenarios provided on the previous chapter. These growth rates by economic sector, as explained in detail on the previous chapter, are assumed based upon the JICA team survey. This is the very basis for the energy demand forecast model. The 30 years period is, for a simplicity sake, divided into three periods, i.e., 5 years from 1996 to 2000, 10 years from 2001 to 2010, 15 years from 2011 to 2025.

As shown the average annual growth rate of GDP for the last 10 years between 1985 and 1995 was 6.1%. Likewise, the growth rates in forecast for the first 5 years from 1996 to 2000 will be 5.4 %, the next 10 years 5.3 % and the last 15 years 5.1%. The average growth rate during the entire 30 years is 5.2 %. The second table of Table 7.3.1 indicates the high growth case, which marks 5.7 % for the 30 years period, and the last table indicating the low growth case at 4.9 % on average.

As depicted on the related chapter on the present situation and future of the macro economy, it would be not easy, however, to make investment, private and public, as much as expected to incur anticipated economic growth toward the next century. The high growth case bases the realization of the high investment anticipated, resulting in high energy consumption, and the low case bases the low level of investment and resulting low energy consumption. Thus, the likelihood of the high case is less than that of the low case. The economic growth rate for the entire period in forecast, the next 30 years, will be around 5 %, as common sense suggests.

Table 7.3.2 to Table 7.3.4 show various macro economic indicators for the references of the user of the energy demand model, such as GDP investment ratio(Table 7.3.2), public finance balance(Table 7.3.3) and trade balance(Table 7.3.4), which are not directly related to the forecast outcomes of the energy demand model.

Table 7.3.5 shows the trend of labor productivity and their average annual growth rates. The labor productivity is derived by the product value for a particular sector being divided by the number of labor employed for that sector.

The labor productivity is known to grow steadily as the economy is at the growing stage.

The total labor productivity for the base case has increased about 3 times in the 3 decades. Or the average annual growth is 3.7 % for the base case, 4.0 % for the high case and 3.5 % for the low case.

Table 7.3.6 indicates the past and future forecast for the Consumer Price Index(CPI) and GDP deflator between the year 1985 and 2025, which have been obtained through the regression analysis. The present CPI is 7 % on average, which will slow down to near 4 % in the 30 years. And the figure of the base case is surrounded by that of the high case, 4.7 % and that of the low case, 4.3 %, consequently.

Table 7.3.7 to Table 7.3.11 summarize the major outcomes of the energy demand forecast model.

Table 7.3.7 describes the energy demand forecast by sector, i.e., manufacturing, commercial and transport and household and its total on final energy demand base.

The present demand for the base case is 0.4 million TOE, will change to 0.5 million TOE in 2000, 0.9 million TOE in 2010, and 2 million TOE in the year 2025 eventually. On the other hand, the high case records 2.8 million TOE and the low case 1.7 million TOE in 2025.

The per capita energy consumption is 0.4 TOE in 1995, will rise to 0.5 TOE in 2000, 0.9 TOE in 2010 and 2.1 TOE in 2025 for the base case. The energy consumption will increase as income rises, no doubt. The high case marks 2.8 TOE and the low case 1.7 TOE in 2025.

Table 7.3.8 shows energy demand by type of energy sources on primary energy supply basis, including the energy inputs for electricity generation. The country is now at a period of steady economic growth. As well known, the economic growth corresponds with electrification ratio. The energy inputs for electricity is 40 % in 1995 on the base case, will rise to over 60 % in the year 2025. The high growth case, on the contrary, marks 63 % in 2025, less than that of the base case, perhaps because the manufacturing sector requires more non-electricity energy as economy marks higher growth. The low case makes the inputs for electricity relatively higher since the economy, that is, the manufacturing sector, is not growing as anticipated.

After the year 2010 to the year 2025, a number of the coal fired electricity generations will be introduced on the plan(please refer to the related chapter), the coal demand during the corresponding period will increase significantly, simultaneously reduce the fuel oil and kerosene demand for electricity generation. Also it indicates a large reduction in charcoal and firewood being substituted by LPG for household energy. The per capita energy demand in terms of primary energy basis is 0.5 TOE in 1995, reaching 2.9 TOE in 2025. Likewise, the high case records 3.5 TOE and the low case 2.5 TOE in the final year of forecast.

Table 7.3.9 indicates the trend of so-called energy unit, which can be obtained by dividing energy demand with the product value. The base case of the electricity demand shows the energy unit of 2025 is up to 1.75 times that of 1995, implying the electricity energy unit will be rising at a rate of 2 % for the next 3 decades. In contrast the energy unit for non-electricity will not rise as much as that of electricity. On the whole, the energy unit will shift from 11.4 TOE/million Rupee in 1995 to 19.3 TOE/ million Rupee at an average annual rate of 1 % plus.

In contrast with the base case, the trend of the high case shows higher, and the low case lower than the base case. This implies that for the high case the incremental energy demand to produce incremental amount of product tend to be higher than the incremental GDP due to higher economic and industrial activities in the high case. The low case shows the contrary.

In considering the present economic stage of the country and the given natural condition, i.e., the island country, the energy unit will inevitably increase slowly as the economy grows, just as an energy unit increased slowly in a country like Singapore at a similar economic stage.

The last two rows on the Table show the electricity and energy consumption(on primary energy supply basis) per capita. The rapid electrification is reflected on the increase of electricity from 0.8 MWh in 1995 to 4.7 MWh in 2025 at a rate of 6 % annual growth.

6

Table 7.3.10 indicates so called the income elasticity of energy by sector, manufacturing, commercial, transport and household. The income elasticity is a major and useful indicator when discussing energy policy. The energy growth rate during a particular period being divided by the income or GDP growth rate during the same periods results in the income elasticity of energy. Generally, the indicator exceeds one at economic growth stage, and converges to one when economy stabilizes. At the base case, that of manufacturing sector changes from 1.5 to 1.2, that of the commercial sector unchanged at the level of 1.5, that of the transport changes from 1.2 to 0.6, and that of the household from 0.7 to 0.8. As a whole, that of the electricity in total shifts from 1.8 to 1.2, that of the energy from 1.3 to 1.1. The similar trend can be observed for the high and low cases as well.

Table 7.3.11 summarizes then key electricity data in the master file. The electricity demand in 1995 is 0.9 TWh, moves up to 8 TWh in 2025. The average annual growth rate is 7.2 % for the base case, 8.0 % for the high case and 6.6 % for the low case, respectively.

Combining the total electricity demand, and the load factor and self consumption and loss anticipated in the future, one can derive the peak electricity demand, implying the supply capacity of the electricity generation for a particular year. The peak electricity is 200 MW in 1995, exceeds 1600 MW in 2025 for the base case. At the high case, the total demand in 2025 is 10 TWh and the peak 2100 MW, and the low case, 7 TWh and 1400 MW, respectively. The non-symmetricity of the high and low cases centering on the base case may reflect that of the three economic growth rates for the 3 decades, that is, the economic growth, 5.2 % for the base, 5.7 % for the high and 4.9 % for the low case.

Table 7.3.12 comprises a series of the energy balance tables starting from 1995(current), 2000, 2010 to 2025. These figures are taken from the energy data base of the past and the future in forecast . 1995 table shows the present energy balance by sources of energy and the three tables in the other years are made based upon the three cases in forecast after the year 2000.

7.4 Prospect of New Energy Development (Potential of New Energy to be commercially applicable by AD2025)

Presently, in Mauritius, the new energy, which is being used in the commercial scale, is only solar energy for the water heaters, which are installed in the households, hotels, restaurants etc. The number of the water heaters installed in Mauritius have reached to 18,000 (7.5% of total household). In addition, the wind power generation was introduced on semi-commercial scale in the past (180kW one and 40 kW four). However, except one unit in Rodrigues island most of the units mechanically failed by the cyclone, and operation are interrupted. At present, no positive activities for development of new energy utilization in the country are not existing, and therefore the significant increase of new energy supply in the country in near future seems unlikely. However, in the long term the development of use of new energy will be promoted under the condition of rise of The cooperation between the electricity tariff and/or the cost of petroleum fuel. Government and the private sector to develop new energy technology to improve the design of wind mill or solar heater to withstand the natural conditions of the country and to provide soft loans required for installation of such new energy facilities is very much desirable. In general, energy efficient new plant require significant initial investment, which may be the obstade for the individual parties to provide for the implementation without adequate assistance from the Government. In any case, there is the potential to develop the energy supply from new energy sources up to 1-3% of total energy requirement in future.

In addition to the solar heat and the wind energy, the utilization of photovoltiac energy has good possibility to be adopted as a new energy supply in the country. At this moment, the cost of photovotiac power supply is still costly than the traditional fossil fuel power generation. (Ref. 6.2.1)

However, the progress of the technology improvement is very rapid and the cost will be competitive to the traditional energy within 5-10 years. The sun shine in the country is adequate for this technology. The solar power generation by the large office buildings or the power supply in the isolated island will be the most probable application in future, but the quantitative assessment for the future application is not possible at this stage.

Further, the technology of co-generation of electricity and heat for large office building, hotel, hospital etc. have already developed in the industrially developed countries. This scheme may be implemented near future in the country.

However, the technical fundamental, which is required to develop the application of such sophisticated technology must be established at the first place.
