Figure 10.2.3 Locations of 25 Automated Continuous Stations in Jabotabek

Task 2 : Arrangement for Legal Support

The Ministry Decree (Ref. 191) listed recommended analytical methods for each air pollutants. However, some of those methods are not applicable for continuous monitoring. BAPEDAL has to issue supplementary decree for the suitable methods. As for reference, one copy of JIS for pollution was presented each to Air Pollution Control Directorate and EMC of BAPEDAL.

If necessary, also legal support shall be arranged for the combined efforts of DKI Jakarta and three Kabupatens with BAPEDAL.

Task 3 : Installation of Monitoring System

Analytical equipment of various principles are available in the market. The same type of equipment is preferable for monitoring of the same pollutant from the viewpoints of data conformity, operation, and maintenance. EMC has to prepare specification of each equipment with the cooperation of KPPL. BAPEDAL Headquarters is better to place order for purchasing instead of purchasing by individual Kabupatens and KPPL. Table 10.2.4 is a list of analytical equipment required in one monitoring station with a suggested monitoring method.

Table 10.2.4 Monitoring Equipment in One Station

Items	Monitoring Method
SO ₂	Continuous UV fluorescent method
NOx	Continuous chemiluminescence method
O ₃	Continuous UV absorptiometry method
CO	Non-dispersion infrared absorption method
SPM	β ray absorption method
HC	Gas chromatograph(using FID) method
Wind Direction	Wind vane & Anemometer
Wind Velocity	Wind vane & Anemometer
Temperature	Electrical Resistance Thermometer
Humidity	Hair Hygrometer

The equipment should be placed in a container at a station. A small mobile type is better than a house type, since it occupies smaller space when located in public space like in a park and easier to borrow a land, and, if necessary, easier to relocate to better place. Table 10.2.5 shows a specification of the container.

Table 10.2.5 Specification of Station Container

Items	Specification
Dimensions	4.19 L × 2.13 W × 2.38 H (in meter)
Materials	Aluminum Sheet (walls), Steel (Flame)
Power Source	AC 220V 4500 VA
Facilities	Step-down Transformer
	Distribution Panel
	AVR
	Air Conditioner - Automatic start after black-out
	Ventilation Fan
	Gas Cylinder Rack
	Room Lighting
	Air Sampling System
	Pole for Wind vane & Anemometer

Table 10.2.6 explains required equipment at central (in KPPL and Kabupatens) and BAPEDAL data stations, and each of monitoring station for data transmittal and management. The central data acquisition stations in KPPL and agencies of Kabupatens should have function to inspect conditions of a monitoring station when it indicate mal-functioning by sending abnormal data.

The manufacturer should be mobilized for installation, initial calibration, and commissioning of the whole system. The manufacturer should have an authorized agent near Jabotabek in order to respond quickly to the requests of supplying spare or consumable parts, complicated maintenance, or repair. Almost all equipment will be imported from overseas.

Task 4 : Organization of Human Resources

Requirements of human resources to manage, operate, and maintain the system are tabulated in Table 10.2.7. KPPL which is going to have 10 monitoring stations may need one person for system management, two for data management, and 5 to operate and maintain monitoring stations. These people can do the same for 16 stations in the future. One Kabupaten agency may need one for system management, one for data management, and 3 for the stations.

Table 10.2.6 Requirement for Data Transmittal and Management

Station	Hard or Soft	Equipment, etc.	Remarks
Each at Central and BAPEDAL Data Acquisition Stations	Hardware	Telephone	
		Modem	
		Personal Computer	I B M Compatible (Operable on WINDOWS 3.1 or newer)
	Software	Color Display	
		Laser Printer	Size A3
		Data Transmittal	
		Data Management	Note *
Each at Monitoring Stations	Hardware	Telephone	
		Modem	
		Local Converter	
		Modem Adapter	
		Personal Computer	I B M Compatible

Note * - The software is operable on WINDOWS 3.1 or newer editions, having capability to plot and table data, and having following additional possibilities:

- a) to refer and correct obtained data
- b) to input data
- c) to change color to display high concentration or different kinds of data
- d) to input various specifications for data acquisition and compilation
- e) to connect with maximum 16 monitoring stations
- f) to convert a file to ASCII file and to a commercially available spreadsheet file

Table 10.2.7 Staff Requirement for the System

Station	Job Description	Number
BAPEDAL Data Acquisition	1. Whole System Management	1
	2. Whole Data Management	2
One Central Data Acquisition Station	1. System Management	1
	2. Data Management	2 or 1
	3. Operation and Maintenance of Monitoring Stations	5 or 3

Roles of system and data management are better to be occupied by experienced officers in pollution problems. One chief engineer is required to lead a group composed of technicians for operation and maintenance of monitoring stations. The chief engineer should be trained in EMC or KPPL for longer, or possibly to

be trained in overseas.

Equipment used for monitoring ambient air quality is usually highly sophisticated and fragile to handle, although they are highly accurate and easily operable. Technicians who are going to handle the equipment have to be well accustomed to operate, inspect, maintain, and calibrate the equipment by training. Training courses are listed in Table 10.2.8. The training has to be carried out in a classroom and in a monitoring station with actual operation of the equipment. EMC and KPPL have similar stations and sufficient technologies to teach technicians from Kabupatens Bogor, Tangerang, and Bekasi. Outside consultants or manufacturer's agents may also be able to help the in-house teachers.

Teaching in a monitoring station will need five days for one group in addition to the classroom lectures for actual operation and maintenance of the corresponding equipment. The one group is better to be organized in small number with less than 3 trainees. Almost person to person training is recommendable.

During the Study, technologies related to maintenance and management of monitoring stations were transferred to the Indonesian Team from the JICA Team verbally and in writing, occasionally using manufacturers' manuals. Important items are recorded as Note on Management of Ambient Air Monitoring Stations in Supporting Volume.

**Table 10.2.8 Ambient Air Monitoring Courses for Technicians
(Classroom)**

No.	Contents	Hours
1	Air pollution and air monitoring in general	4
2	Meteorology and pollutant dispersion	2
3	Instruments - principle, configuration, operation, maintenance, etc. - for meteorological observation	2
4	ditto - for Automatic SO ₂ Analyzer	3
5	ditto - for Automatic Carbon Monoxide Analyzer	3
6	ditto - for Automatic NO _x Analyzer	3
7	ditto - for Automatic Oxidant Analyzer	3
8	ditto - for High Volume Sampler	2
9	ditto - for Automatic SPM Load Analyzer	3
10	ditto - for Automatic Hydrocarbon Analyzer	3
11	ditto - for Data Management System (report preparation)	3

Task 5 : Preparation for Operation and Maintenance

Before the operation of the monitoring system, methods of data compilation and maintenance have to be established and to be understood in all agencies which participate in the system.

Data should be compiled for one hour, one day, and one year averages, and to some kinds of pollutants for three hours or eight hours as required by the ambient air standards. Hourly and daily average data can be compiled monthly as preparation to publish in the format included in the data volume of this Final Report.

Maintenance of analytical equipment is mandatory to acquire accurate data for longer period continuously. BAPEDAL has to prepare a maintenance program including maintenance and inspection methods, frequency of maintenance and calibration, timing of overhauls, timing of part renewals, etc. Manufacturer's manuals and Note on Management of Ambient Air Monitoring Stations in Supporting Volume are helpful for the preparation. Besides maintenance by operators, the monitoring analyzers are needed for periodical intensive maintenance (half yearly and annual) by manufacturers or their authorized local agents to keep the accuracy to be high and the integrity to be firm for longer period. Table 10.2.9 is a typical inspection and maintenance schedule. Annual maintenance overhauls each equipment. The right column is for annual working days of laboratory operators in the 10 monitoring stations, assuming one operator to witness the manufacturers work in the stations.

Table 10.2.9 Inspection and Maintenance of Automated Monitoring Station

Time Schedule	Frequency	Carried out by	Schedule for	Annual Operators Required/10 Stations
Weekly	27 times	2 Lab experts	3 stations/ 1 day	184 person-days
Biweekly	13 times	2 Lab experts	3 stations/ 1 day	88 person-days
Monthly	12 times	2 Lab experts	1 station / 1 day	240 person-days
Three Monthly	2 times	2 Lab experts	1 station / 2 days	80 person-days
Half yearly	1 time	Manufacture	1 station / 3 days	30 person-days
Annual	1 time	Manufacture	1 station / 6 days	60 person-days

When damaged, manufactures' agents shall be consulted for repair. A long term maintenance contract with the manufactures or their agents is recommendable.

There may be inadequacy of local agent for the services of the above at the moment, since the equipment is new and not so popular in Indonesia. However, the owners and the agents should cooperate to improve capability of both sides.

(4) Time Schedule

Table 10.2.10 is to show necessary time schedule targeting the year 2000 to start commissioning the monitoring system. The purchasing, including preparation of equipment specification and installation are critical for the schedule. One year is allocated to procure and ship analytical equipment from overseas.

Table 10.2.10 Time Schedule for Strengthening of Ambient Air Monitoring System

Task		1997			1998			1999			2000		
1	Sites			→									
2	Legal			→									
3	Equip.							→

(5) Required Resources

A. Unit Prices

	(in 1,000 Rp.)
Monthly Wage - System Management	800
Data Management	300
Trainer at EMC or KPPL	300
Chief Engineer Data Acquisition	300
Lab Expert	200
Outside Work Allowance (one person per time)	25
One Data Acquisition Station	58,000
One Monitoring Station in a Container (without Data Transmittal System)	
SO ₂ Analyzer	75,496
NO _x Analyzer	63,540
O ₃ Analyzer	122,000
SPM Analyzer	66,376

CO Analyzer	92,688
NMHC Analyzer	130,192
Meteorological Observation Equipment	70,800
Miscellaneous Equipment	45,280
Container	190,000
Total for One Monitoring Station	856,372
One Data Transmittal Unit	28,320
Monthly Electricity Cost (3000VA/One Station)	530
Annual Maintenance of One Monitoring Station	26,300
Daily Contract Service	600

The above equipment estimate is based on Japanese catalogue price, valid in early 1997, with conversion factor of Rps 20 per one Yen, and does not include various charges of customs clearance, taxes, transportation, etc. Annual maintenance cost of consumable and spare parts for one station given above is not required for the first year of the newly installed stations. Such cost for two years is included in the initial purchase price. However, existing stations in DKI Jakarta require the cost.

(6) Strengthening of Institutions and Legislations

The present institutional/legislative framework is not enough to successfully carry out this countermeasures in the future. The following preparations are necessary :

- Reinforcement of staff in duty in BAPEDALDA, L-BLH, BLK, BPPI and L-PU, and
- Enactment of 'Air Pollution Control Law'

(7) Evaluation

Local agencies concerned including KPPL and MOH have experiences in ambient air monitoring and sample analysis, using the existing stations. BAPEDAL has also such kind of experiences for five years. Although these agencies' staff in charge of monitoring took technical training at the actual monitoring sites through the present JICA Study period, the staff should be trained continuously for technicians of monitoring and sample analysis to collect useful monitoring data. Necessary O&M materials of these countermeasures should be supplied locally and periodically.

Publication of the monitoring results through the electric board existing along the

main traffic roads or statistical books will appeal the atmospheric situations to and bring up incentives for air conservation to local people.

Major cost for this countermeasures is for investment of equipment and facilities to sample and analyze ambient air of the Jabotabek region under the proposed monitoring network and system. The cost is beyond BAPEDAL's and local governments' regular budget for environmental conservation. Therefore their financial deficiency should be covered by raising the additional funds.

10.3 Preparation of Stationary Source Inventory (2-A)

(1) Action Justification

More than 80% of SO_x, nearly 30% of NO_x, and over than 50% of SPM are emitted from stationary pollution sources in Jabotabek. Although current air quality satisfies national and local standards, increases of industrial activities in the area promise that pollutant emissions will violate the standards in the future if no countermeasure is implemented.

In order to prepare stationary source inventory, stationary sources have to be identified with their locations at first. Stationary sources can be consisted of factories, office buildings, households, and so on. These have facilities which emit SO_x, NO_x and PM, including boilers, diesel engines, incinerators, furnaces, ovens, dryers, etc. Secondly, those emission rates have to be determined by measurement and/or calculation.

In the Study, 91 factories responded to the 300 questionnaires distributed, and pollutant emissions were actually measured at 36 facilities. There were 2000 factories identified by the JICA Team in Jabotabek. There must be multiple facilities to emit air pollutants in one factory. Also the 91 factories consumed less than 20 % of sales amounts of HSD, IDO, Kerosene, and LPG in Jabotabek. Emission rates of 36 facilities measured in the Study were only one spot data. Data on different capacity and on other facilities including non-combustion emission sources are needed to improve the inventory.

The reason of these small coverages were because of limits of time, manpower and budget in both Japan and Indonesian sides. More should be surveyed and their pollutant emissions be measured in order to improve the accuracy of emission

inventory from the stationary sources. Technologies and know-hows to prepare the inventory were well transferred in writing and through OJT during the Study period to the level that the counterparts of the Indonesian Team were able to carry out the related tasks by themselves.

The information for the preparation of stationary source inventory should include locations, kinds of pollutants, their emission rates and patterns. The information should be renewed yearly since it is varying frequently by increasing or reducing production capacity, converting a type of fuel, changing operation patterns, or else.

Air pollution is a wide spread phenomena. It can not be contained in one single region. Pollutants disperse tens of kilometers into far remote areas on weather conditions. Each Kabupaten or city in Jabotabek may individually have respective information on stationary sources or facilities. However, there is no single agency which keeps information on stationary sources or facilities as a whole in Jabotabek. It is under the jurisdictions of both governors of West Jawa Province and DKI Jakarta. As BAPEDAL is in the position above the both local governments and has function to implement pollution control measures (Ref. 141), BAPEDAL is the best agency to implement this action plan with the cooperation of Kabupatens of Bogor, Tangerang, and Bekasi, and DKI Jakarta.

This project can be a pilot of similar ones to be implemented in industrial and supposed-to-be polluted regions in Indonesia.

(2) Objectives

The main purpose of this action plan is to prepare the stationary source inventory by expanding the data generated by the joint efforts of the Indonesian and JICA Teams in the Study. The coverage rates of questionnaire survey, flue gas measurement and fuel consumption shall be increased. The inventory will be applied for comprehension of current air emissions, comparison with emission standards, planning of emergency counter measures and issuance of various reports.

By implementing the action plan, the project will accomplish following objectives:

- Strengthening of institutional capacity at both the central and local levels
- Development of environmental impact management process in BAPEDAL
- Development of the partnership of officials with the industrial community
- Centralization of the pollutant emission information possessed by other agencies
- Pilot project of similar ones needed for industrial regions in Indonesia

(3) Scope

The project is mainly to review the previous studies, to identify stationary sources, to carry out questionnaire survey, to arrange for legal support, to train technicians for measurement of flue gases, to purchase necessary equipment for the measurement, and to compile data for use. It is divided into eight tasks as described in below.

BAPEDAL which has related technologies and know-how shall spearhead the project with cooperation from DKI Jakarta, and Kabupatens of Bogor, Tangerang, and Bekasi in Jabotabek. EMC and Center for Information Development and Environmental Compliance, both of BAPEDAL, play critical roles in the project within their functions.

Task 1 : Review of Previous Studies

When authorized, BAPEDAL has to form a project team including member from Kabupatens and DKI Jakarta for implementation of this action plan. The JICA Team prepared and presented Air Pollution Control Directorate and EMC of BAPEDAL, each one copy of "Stationary Pollution Source Study Guideline - July, 1996". The Guideline and the results of the Study have to be reviewed by the project team and to be placed as the threshold of the project. Others studied by international or domestic consultants shall also be reviewed.

Task 2 : Identification of Stationary Sources

Stationary sources emitting SO_x, NO_x and PM into ambient in considerable amounts are factories and large buildings. Emission is caused by combustion of fuel or processing materials. Large buildings such as offices, hospitals, theaters, indoor sport arenas, etc. have substantially large boilers or generators.

The Study Team purchased and presented to Air Pollution Control Directorate of BAPEDAL the voluminous data book of Indonesian factories (Ref. 93). There were 2061 factories (910 in DKI Jakarta, 298 in Bogor, 566 in Tangerang, and 287 in Bekasi) listed in Jabotabek. The book contained name, address, date of establishment, category, line of business, production capacity, started year of operation, number of employees, etc. The JICA and Indonesian Teams of the Study found the information to be somewhat incorrect or obsolete in this 1993/1994 edition. However, the information contained in the book can be used for the time being by the project team. If the new edition is available, the project team has to purchase it from the publisher. The JICA Team also presented to Air

Pollution Control Directorate a list of starred hotels and buildings having floor space larger than 5000 m² in DKI Jakarta (Ref. 94).

The project team should make efforts to renew the above information. Member from Kabupatens and DKI Jakarta is in the position to contact factories and others locally. Each local agency needs to keep the local information and BAPEDAL has to keep it as the central planner in Jabotabek, always to be current. In the future, BAPEDAL has to keep current the information of whole Indonesia in the current governmental organization.

Task 3 : Arrangement for Legal Support

BAPEDAL's role is to assist the President of the Republic of Indonesia in environmental impact control which includes the prevention and control of environmental deterioration, and the rehabilitation of environmental quality, in accordance with the prevailing statutes and regulations (Ref. 141). BAPEDAL must draft regulations and decrees to make this principle more effective and to give protection to its activities. As for this action plan, following articles are better to be included in the drafts.

1) Information flow to BAPEDAL

The information mentioned in Task 2 must be reported automatically to BAPEDAL without soliciting it from another agencies. For the large sized and new factories and buildings, BAPEDAL can obtain information through AMDAL (Environmental Impact Analyses) Committee in which Directorate Environmental Impact Analyses of BAPEDAL has a permanent membership.

2) Reporting duty of factory owners, etc.

Owners or operators of factories and buildings are not obliged to answer BAPEDAL's questionnaires currently. During the Study period, an officer or two of BAPEDAL had to visit a factory to ask for filling out the questionnaire with having a formally signed letter of the Directorate Head. If possible by a legal step, mailing may mitigate BAPEDAL's or local agency's load of this kind.

Task 4 : Questionnaire Survey

Questionnaire survey of the stationary sources is the most powerful method to know the current emission rate in Jabotabek, if the answering rate is high and accurate. The form sheet which BAPEDAL prepared in the Study can be used for the questionnaire survey. The necessary information includes name, address,

date of establishment, line of business, production capacity, started year of operation, number of employees, facility name of pollutant source, annual fuel consumption, kind of fuel, height and top section area of stack, emission rates of SO_x, NO_x, and PM, and flue gas temperature and volume, operational time pattern, etc.

Distribution and collection are the work to be carried out by the member from Kabupatens and DKI. The owners or operators should know all the answers, because of the BAPEDAL's Emission Standards Decree (Ref. 110). However, there are lack of engineering capability in some of factories to answer. The project team needs to assist them for filling out or confirming the answers by visits (a role of project member from Kabupatens and DKI Jakarta) or else. Also because of the costs and necessary expertise for flue gas measurement, it will be a burden to answer emission questions for smaller factories.

The project team has to review the answers and, if necessary, to confirm the answers by contacting answerers. For the review, the team member needs experience on industrial engineering. Compilation by US-EPA (Ref. 208) is the first to be referred by a reviewer if the answered facility is new to the reviewer. The JICA Study Team presented one copy each of the compilation to Air Pollution Control Directorate of BAPEDAL and EMC. Facilities not listed in the reference or burning un-common fuels have to be investigated further in details including flue gas measurement or/and fuel analysis.

When no flue gas measurement is planned at a facility burning un-common fuel, fuel analyses are necessary to calculate SO_x emission and flue gas rate for the inventory, and to assume NO_x and PM emissions. For commonly used fuels, the data analyzed in the Study and others available from fuel suppliers are applicable for estimation of SO₂ emission and flue gas rate, because of almost consistent properties of a respective kind of fuel.

Task 5 : Training Technicians for Emission Measurement

The Central Government of Indonesia has a policy to give powers to local governments. Agencies in Kabupatens other than KPPL in DKI Jakarta do not have enough capability to measure emissions from the stationary sources. Meanwhile in Jabotabek, many factories are going to be constructed outside of DKI Jakarta.

EMC has people well trained in the Study and in equipment handling, which is complied with the Indonesian Guideline for Air Pollution Control (Ref. 227) to measure rates of emissions from stationary sources. EMC as the reference laboratory is in the position to train technicians of the Kabupatens. And

technicians of KPPL have to visit EMC to make the measurement procedures to be uniform in the project. At least two technicians from each Kabupaten agency are required as trainees at EMC. They will be trainers in return at each Kabupaten and DKI Jakarta, if increased member of experts is foreseeable in the future.

The training is required in classroom and at site. Table 10. 3. 1 gives necessary courses in the classroom. BAPEDAL shall have an arrangement with an industrial sector for use of its facility as a training site. The site training - OJT - will require at least two full days at one facility for the start and two days for two other facilities (total three different facilities for measurement) in one Kabupaten.

This training may become quite useful when the decree for emission standards (Ref. 110) becomes widely observed by owners and operators of factories. Each local agency must back-check the data reported from the owners, etc. by measuring in spot using own equipment.

Table 10.3.1 List of Stack Gas Measurement Training Courses in Classroom

No.	Contents	Hours
1	Air pollution and stack gas measurement in general	4
2	Shortcut of fluid dynamics on gas flow	1
3	Requirements for measuring site - location, nozzles, safety, etc.	4
4	Explanation of standard procedures for measurements	8
5	Explanation of equipment for use (theory, operation, calibration, cleaning, maintenance, etc.)	12
6	How to make a report (calculation, etc.)	6

Task 6 : Procurement of Measurement Equipment

Table 10. 3. 2 shows the minimum requirement in each Kabupaten, DKI Jakarta, and EMC.

The same procedures and the same types of equipment which comply with BAPEDAL's Decree KEP-205 (Ref. 227) are preferable for the project in each local agency in Jabotabek. The project team has to prepare specification of each equipment with the help of EMC experts and to purchase those for EMC, DKI Jakarta, and three Kabupatens from reliable manufacturer who can supply consumable and spare parts during the life of the equipment and also can possibly mobilize local service personnel upon request.

Other than cars and laboratory space, major equipment may be needed to be

purchased from overseas vendors.

Task 7 : Measurement of Pollutant Emissions at Sites

The Study found in Jabotabek 2061 factories within which 445 factories employ 500 or more people (First Grade) and around 1000 factories do between 100 to 499 people (Second Grade). Also the questionnaire survey of the Study found there were around 3.4 facilities in one factory to be the stationary sources in Jabotabek.

Measurement of actually operating facilities is mandatory to confirm emission rates and finally improve accuracy of the inventory. Emission rates of some facilities have been known already from the previous projects (such as the Study or the US-EPA Compilation (Ref. 208)). However, there are facilities not found in the reference, differently operated, or unique to Indonesia.

From the experience in the Study, measurement at two facilities in a week is possible in average. The trained four teams (one in each Kabupaten and DKI Jakarta) can measure flue gases from around 300 facilities (around 22 factories in one Kabupaten or DKI Jakarta) in a year. One team composes two field and two laboratory technicians.

Construction work for installation of sampling nozzles, measurement platforms, stairs, etc. may be additionally needed in some facilities. Because of the BAPEDAL's Decree for Emission Standards (Ref. 110), the owners and operators of the factories and buildings installed them voluntarily in the Study. They are expected for this matter to be the same in this project.

Table 10.3.2 Flue Gas Measurement Equipment in One Agency

Item	Equipment	Sets	Remarks
SOx	Turbidimetric Method	3	
NOx	Phenol Disulfonic Acid Absorptiometry	3	
PM	Manual and Auto Sampling Sets	-	each 1 set
H ₂ O	CaCl ₂ Absorption	1	
Velocity	Pitot Tube Velocity Meter	1	
CO ₂ , O ₂	Orsat Gas Analyzer	2	
Balance	Electronic	1	
Others	Thermometer, Pressure Gage, Chemicals, etc.	1	
Car	Motor vehicle to transport equipment to sites	1	
Laboratory	Photoelectric Spectrophotometer, Dryer, Preparation of reagents, etc.	1	

Task 8 : Compilation of Stationary Source Inventory

Local agencies have to file sheets of reviewed answers of the questionnaire and flue gas measurement data in one cabinet, and send copies to the core project team member in BAPEDAL. Finally, the project team has to compile the collected data for further use locally and centrally. It is recommendable to compile the collected data weekly as a routine work.

The compilation can be carried out using a commercially available spread sheet computer soft, such as Excel or 123. The local team member will input respective local information into own computer and send a copy of the floppy to the BAPEDAL member who input into the BAPEDAL's computer by combining four local files.

The results stored in the computer can apply for a) comprehension of emissions, locally and totally, b) comparison with emission standards and issuance of warning to individual factory, c) the planning of emergency countermeasures when air pollution exceed the national or local standards in some region, d) planning of emission reduction, factorywise and regionwise, and e) issuance of various reports as required.

(4) Time Schedule

Table 10. 3. 3 is composed to show necessary time schedule, assuming that core officers of the project team work exclusively for the above tasks, without having any other intensive assignment.

Table 10.3.3 Time Schedule for Preparation of Stationary Source Inventory

Task		1998			1999			2000			2001		
1	Review	→											
2	Identif.							→					
3	Legal		→										
4	Question.							→					
5	Training							→					
6	Equip.					→							
7	Measure										→		
8	Compile											→	

(5) Required Resources

A. Manpower

BAPEDAL shall compose a project team to implement this action plan, when it is authorized. The team needs two core officers (including one project manager) and necessary clerks to manage the project. One of them should have experience in industrial engineering.

Two EMC engineers trained for flue gas measurement in the Study will teach two trainees each from respective Kabupatens and DKI Jakarta.

Twelve Kabupaten officers are estimated in the budget below. The breakdown of the twelve is 5 for DKI Jakarta, 3 for Tangerang, and two each for Bogor and Bekasi, from the number of existing factories. They need to work for the project 100% for the first one year and in average less than 30% of their loads in the remaining project period. Car drivers will be hired temporally.

B. Investment and Expenses (in 1,000 Rp.)

1) Wages:	Core Project Officers	$2 \times 400 \times (12 \times 3 + 4)$	=	32,000
	Clerks	50 % of the above	=	16,000
	EMC Engineers	$2 \times 300 \times 4$	=	2,400
	Kabupaten Officers	$12 \times 300 \times (12 + 30 \times 0.3)$	=	75,600
	Kabupaten Clerks	50 % of the above	=	37,800
	Kabupaten Technicians	$16 \times 200 \times 16$	=	51,200
	Subtotal			215,000
2) Miscellaneous Office Expenses	30% of the wages		=	64,500
3) Allowance for Outside Work	$2 \times 100 \times 25$		=	5,000
4) Equipment	SOx	$5 \times 30,000$	=	150,000
	NOx	$5 \times 30,000$	=	150,000
	PM	$5 \times 30,000$	=	150,000
(manual)		$5 \times 60,000$	=	300,000
(auto)	Others	$5 \times 65,000$	=	325,000
	Car	$5 \times 70,000$	=	350,000
	Subtotal			1,425,000
5) Wages for car drivers	$4 \times 500 \times 16$		=	32,000
ditto of EMC's	$1 \times 500 \times 4$		=	2,000
Gasoline & others for cars	$6000 \text{ (liters)} \times 4$		=	24,000
	TOTAL			1,767,500

TOTAL

1,767,500

Equipment costs (except cars) include consumable and spare parts sufficient for 1.5 year training and measurement operation, and do not include taxes, custom clearance fees, nor overseas transportation costs. The costs are based on the catalogue prices in Japan, 1996. The conversion rate of Japanese Yen to Indonesian Rupee is Rp. 20 to one Yen. Rp. 4,000 per liter of gasoline are estimated including gasoline, insurance, compensation for small damages, parking tickets, highway tolls, etc.

(6) Strengthening of Institutions and Legislations

As for the institutional and legislative aspects, the following preparations are definitely essential in order to implement this countermeasures :

- Reinforcement of staff in duty in BAPEDAL and L-BLH, and
- Enactment of 'Air Pollution Control Law'

(7) Evaluation

A manual for the inventory survey was finalized and handed to the counterpart agency, BAPEDAL, during the Study. Besides, technical and analytical methods for the inventory survey were successfully transferred to some BAPEDAL staff. The techniques used for inventory is simple. Under these backgrounds, implementation of the preparation of stationary source inventory can be made by BAPEDAL staff technically. In addition, this countermeasures should be carried out continuously to revise the inventory. Because the number and/or kind of stationary sources will vary with the change of the times.

During implementation of the countermeasures, its financial burden on local governments in Jabotabek area is estimated to be very limited. On the other hand, BAPEDAL has to allocate over 1,400 million Rp. as the initial investment cost for implementation. This amount can be mostly recovered by fuel taxation, raising the additional funds, and so on.

10.4 Preparation of Mobile Source Inventory in Jabotabek (3-A)

(1) Action Justification

It was demonstrated that the mobile source had the substantial impact of NO_x to the ambient air in Jabotabek by the Study. However, it was based on the published emission factors adjusted to Jabotabek conditions. The emission factors based on the actual Jabotabek driving characters are required to have better inventory and its distribution in the area.

The emission factor is variable with driving speed and carrying loads. The speed is always changing due to traffic conditions, second by second. A combination of the varied speeds typical to the city or country is called a vehicle drive cycle mode or simply a cycle mode. There are two kinds of the cycle mode. One is used to certify newly produced vehicles of their emission rates, and is not subjected to frequent changes. Indonesia intends to use the ECE mode, because it is widely accepted in countries where Indonesia plans to export the vehicles. The other is site specific local cycle mode in order to estimate realistic emission factors. In Jabotabek, idling stages seem to be predominant on the congested urban roads, because traffic signal intervals are so long, and the traffic is highly congested. The individual segmental patterns composing the Jabotabek cycle mode will be completely different from those of the ECE mode which BAPEDAL is planning to introduce for the certification. The local mode and inherent emission factors shall be established for the accurate emission inventory of mobile sources in Jabotabek.

BAPEDAL and EMC obtained the Mobile Source Inventory Study Guidelines prepared by the JICA Team during the Study. The Guidelines illustrated tasks needed to prepare the inventory by using published emission factors. The Team prepared the mobile source emission inventory of Jabotabek following to the Guidelines and explained how to estimate the inventory to the Indonesian counterparts at various occasions. Therefore, BAPEDAL has the necessary technologies to do so more accurately and realistically, if the emission factors are known for Jabotabek.

Ministry of Communication (HUB) has a chassis dynamometer system which can measure pollutants in exhaust gas of light duty vehicles such as taxis, passenger cars and motor cycles. This system will be applied for the ECE cycles to issue certificates of newly produced vehicles. From the viewpoint of emission inventory study,

another system of the chassis dynamometer system is required under the control of BAPEDAL. BAPEDAL should have a support from EMC to implement this project using the chassis dynamometer system.

(2) Objectives

The main purpose of this project is to prepare the inventory of mobile source emissions in Jabotabek. By implementing the action plan, the project will accomplish following objectives;

- Strengthening of relationship between BAPEDAL and Ministry of Communication, and local transportation agencies
- Development of partnership with GAIKINDO and PASMI
- Centralization of pollutant emission information

(3) Scope

The project is mainly divided into five components; a) collection of traffic data in each Kabupaten, b) establishment of drive cycles suitable to Jabotabek, c) establishment of a chassis dynamometer system in BAPEDAL, e) generation of emission factors of each car types suitable local traffic conditions, and f) preparation of the inventory.

Task 1: Organization of Task Force Team

BAPEDAL should organize a task force team for the project implementation. Its member will be composed of representatives of HUB, local governments, GAIKINDO and PASMI; total around ten people. BAPEDAL should lead the project and assign individual tasks to all the team member. Also BAPEDAL should find in 1999 a consultant who may be a foreigner capable of the tasks to be followed.

Task 2: Vehicle Market

BAPEDAL shall keep vehicle production and sales amounts in Jabotabek updated with the help of GAIKINDO and PASMI, by using ten categories such as 1) motorcycles and three wheeler, 2) passenger cars, 3) Taxis, 4) minibuses, 5) buses, 6) vans, 7) pick-up trucks, 8) 2-axle trucks, 9) 3-axle or more trucks and trailers, and 10) others.

Task 3: Investigation of Traffic Volume

Each traffic agency of the Kabupatens should monitor traffic volume by vehicle categories, time zones, and days. This must be a routine work for the local agency in charge. Therefore, the task itself is eliminated from the estimation of resources.

Task 4: Preparation of Cycle Mode Test Plan

BAPEDAL should prepare a test plan of drive cycle mode for individual local agencies. The drive cycle modes should be representative of a) highly congested traffic roads, b) relatively un-congested roads, and c) expressways, in each Kabupaten. The test plan will include 1) numbers of vehicle classes to be tested - (in the highly congested roads, some classes will move in the same mode, because unable to disturb the general traffic flow), 2) routes to be measured, days, and time zones, 3) items to be measured and recorded - speed changes in time under different modes of engine operation (idling, acceleration, cruising and deceleration), rpm and torque of diesels, and fuel consumption.

Task 5: Road Tests

BAPEDAL should carry out road tests for the preparation of the cycle modes. BAPEDAL has to rent a 4 wheel vehicle and two motorcycles, and has to purchase a set of test equipment. The 4 wheel vehicle carries the test equipment with a recorder of the data. One officer will instruct the driver the direction and voice to the recorder any road conditions to be noted for the data analysis. One motor cycle will drive through freely on the selected roads to the direction instructed by one officer on the back (the Ojih style). The other motorcycle will carry the test equipment and chase it as much as in the same driving patterns of the forerunner.

The test may need 2 categories (motor cycles and others) on the highly congested roads, 5 categories (motor cycles, taxis, passenger cars, large buses, and slow moving trucks) on relatively uncongested roads and expressways. The tests shall be carried out in rush hours and day time, on week days and holidays. Five routes of one hour drive will be set up for the tests in each Kabupaten. Total 240 tests (60 by the motor cycle and 160 by the 4 wheel car) shall be accomplished in each

Kabupaten. Two tests a day may be possible.

Task 6: Establishment of Cycle Modes

BAPEDAL should analyze the data and develop the Jabotabek test cycle modes. There are two methods for analysis; time segmental method and elemental statistical method. The first one is to divide the data into one time span (for example 10 minutes). And the combination of the several typical segments will be selected for the mode. The second one is to divide the data into each element of modes (idling, acceleration, cruising and deceleration) and statistically predominant elements will be combined to establish the cycle mode. A computer BAPEDAL in possession has to mobilize for the analyses.

Task 7: Purchase of Chassis Dynamometer System

BAPEDAL should specify the chassis dynamometer system with an emission gas analyzer unit, issue a bid package, analyze the bid, and issue purchase order which should include installation guidance, attendance for commissioning, and operators training. The specification will be prepared with the help of HUB, because of their hands-on experiences. As 65% of vehicles produced in Indonesia is the light duty one (taxis, passenger cars, microbus, and vans, under 3500 cc) and new environment-friendly motorcycles and buses are going to be introduced, the light duty gasoline vehicle group is recommended to be targeted for generation of emission factors by BAPEDAL at first.

The chassis dynamometer system is composed of the following:

- Chassis Dynamometer - power absorption: 90 kw
maximum allowable speed: 150km/hr
maximum weight: 3500 kg
- Emission Analyser (CO/CO₂, THC/O₂, NOx) Unit for gasoline engines
direct sampling and constant volume sampling
- Accessories for calibration, adjustment, data recording, etc.

Task 8: Installation and Commissioning

BAPEDAL shall supervise the construction work carried out by subcontractors. Installation of the imported chassis dynamometer system shall be carried out under

the guidance of manufacture's representatives. Commissioning needs for checking the performance of the repaired or newly purchased equipment, also under the attendance and according to the specification of the manufacturers.

Task 9: Operator Training

Before commissioning, key operators shall be recruited and trained in somewhere where the similar unit is available for. The manufacturer can usually receive them for basic training and can introduce one such owner willing to receive and train them. The key operators will operate during the commissioning and simultaneously train other operators under the guidance of the representatives of the manufacturer. The training should include operation, inspection, and maintenance procedures.

Task 10: Generation of Emission Factors

BAPEDAL shall generate emission factors of the light duty vehicles using its now installed chassis dynamometer system under the Jabotabek test cycle and ECE cycle for comparison. The test shall be carried out using vehicles with different types and production years (producers \times different engines \times age spans) in different categories of light duty and gasoline engine.

Task 11: Collection of Emission Factors of Other Categories

BAPEDAL should ask manufacturers and importers of vehicles in other categories than the light duty gasoline vehicles through GAIKINDO and PASMI to generate or estimate related emission factors using the Jabotabek cycle modes.

Task 12: Determination of Average Emission Factor

BAPEDAL should analyze the emission test data and determine average emission factors for HC, CO, and NO_x from each categorized vehicles and for each mode. SO_x emissions can be estimated from the fuel consumption and fuel analyses.

Task 13: Compilation of mobile Source Inventory

BAPEDAL should calculate and compile the mobile source inventory in Jabotabek using the emission factors and following the JICA Team's Mobile Source Study Guidelines.

(4) Time Schedule

Table 10. 4. 1 is composed to show necessary time schedule for each task.

Table 10.4.1 Time Schedule for Preparation of Mobile Source Inventory in Jabotabek

Task	1997	1998	1999	2000	2001	2002	2003	2004
①								
②								
③								
④								
⑤								
⑥								
⑦								
⑧								
⑨								
⑩								
⑪								
⑫								
⑬								

(5) Required Resources

A. Initial Investment of Chassis Dynamometer System

One dynamometer for gasoline light duty vehicles: Rp. 1,400,000,000

One emission test units: Rp. 2,450,000,000

Subtotal Rp. 3,850,000,000

The above cost estimate does not include tax, transportation, custom clearance fee, etc. At the site, needed are for construction and fabrication of all components including local purchase items of housing 400m² of 2 floors, laboratory facilities, foundation, air conditioning, etc. for one dynamometer and emission-test system.

Subtotal Rp. 5,000,000,000

Total investment of BAPEDAL Rp. 8,850,000,000

B. Operation and Maintenance of Chassis Dynamometer System

Two chief engineers, one gas analysis chief engineer, and six operators may need to operate the systems.

Wages: 3 engineers and 6 operators, 10 % of clerical support and 30 % of office expenses

$$3 \times 450,000 \times 1.3 \times 1.1 \times 12 = \text{Rp. 23,166,000}$$

$$6 \times 300,000 \times 1.3 \times 1.1 \times 12 = \text{Rp. 30,888,000}$$

$$\text{Manpower Cost / Year} = \text{Rp. 54,054,000/year}$$

Maintenance is very important for keeping the system to generate accurate and reliable data. Once a year heavy maintenance is required possibly including overhaul for whole of the chassis dynamometer and gas analysis units. Since there is no capable agent in Indonesia, BAPEDAL has to invite experts from overseas. The actual cost for this type of maintenance incurred by the Japanese owners is given below as a reference. The period required for this maintenance is one to two weeks annually for one system.

Water requirement 3,600 liters/day/system : cost negligible

Electricity 50 kw/system (6 hours, 150 days)

$$50 \times 243.3 \times 6 \times 150 = \text{Rp. 10,950,000}$$

Annual maintenance and spare parts (cost in Japan)

$$\text{Rp. 96,000,000}$$

Annual maintenance by contractors (cost in Japan)

$$\text{¥10,000,000/one system} \times 20\text{Rp./yen} = \text{Rp. 200,000,000}$$

$$\text{Utility and Maintenance Cost / Year} = \text{Rp. 306,950,000}$$

$$\text{Total Operation Cost / Year} = \text{Rp. 361,004,000}$$

C. Road Test Costs in 1999 and 2000

$$\text{One 4 wheel car rental with a driver} = \text{Rp. 150,000/day}$$

$$\text{One motor cycle rental with a driver} = \text{Rp. 70,000/day}$$

$$\text{One set of equipment for road tests} = \text{Rp. 4,000,000}$$

$$\text{One 'Recorder and Writer'} = \text{Rp. 4,000,000}$$

$$\text{Soft wares to decode the obtained data} = \text{Rp. 20,000,000}$$

$$\text{Subtotal in 1999} = \text{Rp. 28,000,000}$$

2 Officers (wage, out of office allowance, expences)

$$2 \times 12 \times 450,000 \times 1.3 = \text{Rp. 14,040,000}$$

$$\text{Rental vehicles } 80 \times 150,000 + 30 \times 70,000 = \text{Rp. 14,100,000}$$

Subtotal in 2000	Rp.28,140,000
Total	Rp.56,140,000

D. Foreign Consultant

BAPEDAL should contract at the middle of 2000 with a qualified consultant and retain him or her to the middle of 2002. The work load of the consultant will be 100% in 2001 and 50% in 2000 and 2002 in Jabotabek.

One consultant, monthly fee	Rp. 40,000,000/Month
One consultant, expenses in Jabotabek	Rp. 15,000,000/Month
One round airfare of a overseas trip	Rp. 7,000,000

E. BAPEDAL's Other Expenses

BAPEDAL needs two officers, one 100% and the other 50% of work load from 1998 to 2001, and one officer with 25% work load in 2002 and 2003. In 2004, two full time officers will be needed in BAPEDAL. Two officers in 2000 for the road tests, and 3 officers and 6 operators of the chassis dynamometer system operation have been counted in the above respective section.

The task force member (10 for the estimate) will meet monthly until the end of the project.

One officer wage with supporting clerk and office expenses

Rp.7,020,000/year

	1998	1999	2000	2001	2002	2003	2004
Officer Wage	10.53	10.53	10.53	10.53	1.76	1.75	14.04
Task meetings	0.6	0.6	0.6	0.6	0.6	0.6	0.6
Chassis Dynamo.		3,850	2,500	2,554.05	361.00	361.00	--
Road test	--	28	28.14		--	--	--
Consult's M. Fee	--		240	480	240	--	--
C. in Jabotabek	--		90	180	90	--	--
Consultant's Trip	--		14	14	7	--	--
Total	11.13	3,889.13	2,883.27	3,239.18	700.36	363.35	14.64

in million Rp.

(6) Strengthening of Institutions and Legislations

Institutionally this project will expand BAPEDAL's power over the mobile industry drastically and increase its capability to point out .

(7) Evaluation

BAPEDAL has little technical experience in running chassisdynamometer system. However, there has existed in Bekasi a set of the system owned by the Ministry of Communication (HUB) for about 15 years. So HUB has technical experiences in running chassisdynamometer system. Accordingly, it is necessary that BAPEDAL obtain a technical cooperation concerning chassisdynamometer system from HUB.

Major cost of these countermeasures is for investment of chassisdynamometer system installation. The initial investment cost and the foreign consultant fee for this countermeasures is beyond BAPEDAL's regular budget for environmental conservation. Thus this financial deficiency should be covered by raising the additional funds.

As in the time schedule of table 10.4.1, mobile source inventory would be prepared within 2004. Therefore, no budget is given from 2005 for the operation of the chassisdynamometer system. However, such kind of the emission measurement should be continued to the future to obtain more accurate data for each engine type, production year, and age span. For example, compilation of emission factors by Japan Environment Agency show more than 900 samples for one regulation category of gasoline passenger car. When new type of emission control device or low emission vehicle are introduced in the market, new investigation will be necessary with the chassisdynamometer system. The mobile source inventory will be also revised according to the change of vehicle compositions of Jabotabek in the future, probably in 3 to 5 years interval.
