SECTOR C INDUSTRIAL AND PIGGERY WASTEWATER TREATMENT

1. PRESENT TREATMENT CODITION OF WASTEWATER BY FACTORIES AND PIGGERIES

1.1 Pollution Source Inventory

1.1.1 Factories

(1) List of Factories

In the basin there is a large number of industries from small scale to large scale amounts to about 290 according to the information. However, the factories which possibly cause the water pollution can be limited to a certain number. In this study, the following factories are selected for the inventory survey:

- Large scale factories with more than ten employees based on the 1990 OCEI (Central Office of Statistical Information) census and
- Factories not included in the census, but considered to be significant polluters based on past study results.

Table 1.1-1 shows factory categories or type of industry as well as the number of employees by administrative unit of city and town in the study area. The total number of factories and employees in the study area are 103 and 13,028, respectively.

(2) Location of Factories

Factories are concentrated in the major cities on the basin, such as Las

Tejerías, Cúa, Charallave, and San Francisco de Yare. Particularly in Las Tejerías and Charallave there are many factories with the highest number of employees: There are 3,192 employees in 22 factories in Las Tejerías and 3,830 employees in 21 factories in Charallave. The number of factories and employees are compared by sub-basin as follows (see Fig. 1.1-1).

Location of Factories

| Sub Basin | Tributary | Name of City | No. of Factories | No. of Employees |
|--------------|-----------------|------------------------|------------------|------------------|
| Upper Basin | Tuy River | Colonia Tovar | 1 | 54 |
| | Can. Tiquirito | El Consejo | 2 | 653 |
| | Tuy River | Las Tejerías | 22 | 3,192 |
| | Qda. Guayas | Guayas | 2 | 439 |
| | Qda. Maitana | Paracotos | 7 | 365 |
| | Sub-total | | | 34 |
| Middle Basin | Tuy River | Cúa | 16 | 1,065 |
| | Qda. Maitana | San Diego de los Altos | 1 | 212 |
| | Qda. Maitana | San Jose de los Altos | 1 | 49 |
| | Qda. Charallave | Charallave | 21 | 3,830 |
| | Qda. Charallave | Pitahaya | 4 | 943 |
| | Tuy River | Ocumare del Tuy | 6 | 679 |
| | Tuy River | San Francisco de Yare | 11 | 1,714 |
| | Sub-total | | | 60 |
| Total | | | 103 | 13,028 |

(3) Production Pollution Load

(a) Food Related Industries

Food related industries, which will cause organic pollution, is dominant in both total number of factories and employees; It has 23% of the total number of factories and 31% of employees. Alcohol manufacturers of chiefly rum, have the largest employees among them; One factory in El Consejo employs 573 and another in Ocumare del Tuy, does 440. In Charallave, one food and snack manufacturer has 691 employees.

(b) Non-Food Related Industries

The textile, foundry, and car parts industries, which possibly discharge heavy metals, are the second to the food related industries in the numbers of factories and employees. One manufacturer of ceramic floor tiles in San Francisco de Yare has an exceptionally large number of employees, 1,039.

Other possible polluters include: Tanneries which will discharge large quantities of organic substances and probably also cyanide, chromium and lead; Paint factories; Plastics and synthetic fiber manufactures; Soap and cleaning chemical factories; Other chemical manufactures; Glass and fiberglass factories. These, however, are small in number compared with other industries mentioned above.

The table next is the list of industries whose factories probably discharge inorganic chemicals, mainly heavy metals in their wastewater

Factories probably discharge inorganic chemicals

| CIU | Industrial Category | Inorganic Chemicals | No. of factories (employees) |
|-------|---|---------------------------------------|------------------------------|
| 32311 | Tannery and finishing of leather | CN, Pb, Cr ⁶⁺ | 1(14) |
| 32321 | Industry to prepare tanning leather | CN, Pb, Cr ⁶⁺ | 1(59) |
| 35211 | Manufacture of paint and varnishes | Cd, CN, Cr ⁶⁺ , Hg | 6(914) |
| 35231 | Manufacture of soaps and cleaning products | CN, Pb, Cr ⁶⁺ | 7(821) |
| 36201 | Production of fiberglass | CN, Pb, Cr ⁶⁺ , As | 2(87) |
| 37201 | Production of non-ferrous metals and alloys | CN, Pb, Cr ⁶⁺ | 6(524) |
| 38191 | Manufacture of metallic products, excl. machinery | CN, Pb, Cr ⁶⁺ | 3(183) |
| 38193 | Metal plating | Cd, CN, Pb, Cr ⁶⁺ , As, Hg | 7(833) |
| 38431 | Car parts factory | Cd, CN, Pb, Cr ⁶⁺ , As, Hg | 1(296) |
| 38433 | Automobile spare parts factory | CN, Pb, Cr ⁶⁺ , As, | 5(722) |

(4) Treatment Condition

During this study period 41 factories that were considered to be significant polluters according to past studies and were decided to conduct interview on them for basic information on their establishment including treatment facilities (see Table 1.1-2).

Whatever their industries, many factories were founded over 25 years ago and, in particular, two famous rum factories were founded nearly a half century ago; Ron Santa Teresa started its operation 40 years ago and Industrial Pampero 58 years ago.

Considering the large scale of the 41 factories selected, a problem is that a significant number of them are without a wastewater treatment system (refer to Table 1.1-2). Four of twelve food related factories surveyed have no treatment facilities. In other 29 factories, 14 which may discharge inorganic chemicals do not give any treatment.

Such 41 factories were interviewed including one plant at a sand quarry in Paracotos which is a possible polluter of high turbidity in the Tuy River. This plant of fine aggregate was also listed in the table of the factories.

1.1.2 Piggeries

(1) List of Piggeries

The possible polluters in livestock farms in the study area are piggeries and chicken farms, however, all the waste from chicken farms is recycled as agricultural fertilizer. Therefore, the piggery is the main polluter among them on the upper and middle basin. The list of piggeries in the Study Area is shown in Table 1.1-3.

(2) Location of Piggeries

Piggeries are mostly concentrated around a few areas (see Fig. 1.1-2): Qda. Morocopo and Qda. Guayas in the upper basin, and Ocumare del Tuy and Charallave in the middle basin. The 20 upper basin piggeries with a total of 48,413 pigs and are generally larger than those in the middle basin, where there are 13 piggeries with 23,068 pigs. The area around Qda. Morocopo has the greatest concentration, having 11 piggeries with the effluent from 33,500 pigs being discharged into the creek (see Table 1.1-4).

Compared to the condition in 1988, the number of piggeries in the upper basin decreased from 28 to 20, while stock numbers increased from 38,000 to 48,413 (Table 1.1-5). In the middle basin the numbers of piggeries and pigs decreased from 18 to 13 and 32,000 to 23,068 respectively. Meaning that over the whole Study Area the number of piggeries fell, while the number of pigs is increasing.

(3) Treatment Condition

Most of treatment systems are lagoons, though it is not clear yet how efficiently these are working. However, according to the information several piggeries do not discharge wastes directly into a water course, but use it for irrigation or discharge it on to an open field. Thirty percent (30%) of the piggeries in the upper basin do not discharge waste, while the figure is 23% in the middle basin (refer to Table 1.1-3).

1.2 Water Quality Analysis

(1) Condition of Water Quality Analysis

According to the previous study results, the water pollution in the Tuy River is chiefly due to (1) wastewater from factories, piggeries, residences and (2) sediment transport on the river basin. The pollutants are broadly classified into four; namely, organic substances, toxicants, solid particles (cause of high turbidity), and others.

To confirm the pollution condition from the factories and piggeries, a series of water quality analysis was conducted in the following manner:

(a) Parameter Analysis

The specific parameters were selected for this study from those commonly applied in examining pollutants (see Table 1.2-1).

(b) Sampling Sites and Sampling Times

Sampling sites were selected to confirm the serious sources of factories and piggeries.

The number of sampling sites is listed in Table 1.2-1 and each site location is shown in Fig. 1.2-1.

The sampling and observation with the discharge measurement at each site were conducted once in the first study period.

(2) Results of Water Quality Analysis

(a) Water Quality from Factories

The factories on the basin are classified into two categories by their products: Non-food and food related factories. The wastewater released from these factories has the following qualities:

(i) Non-food Related Factories

Among the non-food related factories on the basin, the main pollutant sources of the Tuy River are textiles, metal works, sand quarries, and tanneries.

The qualities of wastewater from these factories are shown in Fig. 1.2-2 and are explained as follows:

- Organic pollutants released from some factories are over the standard limit, which is 350 mg/l for factories discharging into the sewer system and 60 mg/l for the factories directly discharging into the river. Among the samples from 17 factories, those from 5 factories, discharging directly into the river, were higher than 60 mg/l, and from two factories discharging into sewers were higher than 350 mg/l. For COD, samples from 9 factories had a higher value than the standard limit of 350 mg/l for direct river discharge while two others discharging into the sewers were higher than 900mg/l, the limit.
- Levels of heavy metals in the effluent from factories discharging into the Tuy River are high according to the results; three cases, two for T-Cr and one for T-Hg, were higher than the standard limit.
- In general, the turbidity is not high except the samples nearby the sand quarries. In contrast, SS values from 11 factories among 17 factories are above the standard limit of 80 mg/l for direct discharge to the river and samples from two other factories were above the standard of 400 mg/l for the discharge to the sewer system.
- The pH values from the samples from five factories are out of the allowable range of the standard, while the nitrogen levels of the samples from seven factories were above the standard.

(ii) Food Related Factories

Among the food related factories, the main pollutant of the Tuy

River are from an alcohol distillery, meat processing, and soft drink factories.

The figures for the quality of wastewater from these factories are in Fig. 1.2-3. The following remarks are derived from the results:

- Organic pollutants are dominant in the wastewater. BOD ranges from 5 mg/l to 7,000 mg/l. Six in ten factories released more highly polluted wastewater than the standard (60 mg/l) limit for the factories directly discharging into the river, and five factories also violated the standard limit (350 mg/l) for those discharging into the sewage system. A similar condition can be observed for COD.
- The turbid condition, in general, is not high, judging from the observed values, although SS values of the samples from eight of ten factories were above the standard limit (80 mg/l) while the values of the other samples were higher than the standard limit (400 mg/l).
- The pH values were within the allowable range of the standard. And values above the standard for nitrogen (T-N: 40 mg/l, NO₂ and NO₃: 10 mg/l) were detected from the samples of three factories.

(b) Water Quality from Piggeries

As in the case of the factories producing food related products, the quality of wastewater from piggeries is characterized by organic pollutants as summarized below (also see Fig. 1.2-4):

- Organic pollutants are dominant in the wastewater from the fact that the samples from seven of eight piggeries releasing wastewater into the river were above the standard limit for BOD (60 mg/l) and the samples from five piggeries releasing into sewers were above 350 mg/l. For COD values, all samples from piggeries were higher than 350 mg/l.
- Turbidity and SS were also high in the analyzed data. The samples from seven of eight piggeries releasing waste into the river were above the standard limit (80 mg/l), and for and the samples from five piggeries releasing into sewers were above the limit of 400 mg/l.
- The pH values are within the standard limit. Besides them, the condition of T-N pollution is severe because all factories are releasing more polluted wastewater, above the standard limit of 40 mg/l.

1.3 Influence of Wastewater Discharged from Factories and Piggeries

In the wastewater discharged from factories and piggeries, major pollutants relating to the organic pollution, toxicants and turbidity are included. The influence of the pollution condition of the Tuy River caused by the wastewater discharged from factories and piggeries are summarized as follows:

1.3.1 Organic Pollution

Factory

An alcohol distillery located in the upper basin is the factory having the greatest impact on the water of the Tuy River. A biological treatment plant has been introduced and the present BOD treatment rate is around 95%; COD and SS are 89% and 83%, respectively (see Table 1.3-1). Attention should be paid to the fact that even after treatment the concentration of BOD exceeds 2,000 mg/l, even with the high treatment rate. This level is still well above acceptable limits for effluent being discharged into the river.

The fact that the concentration of the wastewater even after the treatment is at such a high level implies the necessity of overall measures for pollution load reduction including those in the production process, total volume of material used and recycling of water. The introduction of an oxidation pond by the year 1997 has been agreed upon between the factory and the Tuy River Basin Agency. Considering the fact that the effect of the factory on the Tuy River is very large, continued reduction of the pollution load is essential.

Although the treatment rate of BOD by factories with biological treatment plants is generally high, at above 95% for food factories e.g. chicken meat processing, flour milling, dairy produce processing. Furthermore the treatment rates of other parameters range widely, from 60-90% for COD, and 10-90% for SS. With regard to the installation of treatment plants, one third of the total number of the factories remain without any form of treatment. Improvement of the food factories is thus important for the reduction of the pollution load.

The percentage of non-food factories without treatment plants is one half. Improvement in BOD is not good in these factories as is easily imagined from the treatment method. Some of non-food factories, e.g. chemicals and textile producers, discharge high concentrations of organic pollution. Biological treatment is basically preferable for these factories. If biological treatment is not applicable as in the case of some chemical producers, the most appropriate method should be selected.

Piggeries

The effect of the piggeries on the river water pollution is significantly different for those piggeries with oxidation ponds and without any treatment. For example in the case of a piggery located along Qda. Morocopo, pre-treatment is conducted to remove and compost solid wastes, and water is treated with three oxidation ponds. Another example is to utilize water from the oxidation ponds for irrigation of adjacent upland

crop fields. In these cases, more than 90% of pollution could be removed. However in the case of no treatment as in the case of a piggeries located along the Tuy River, 100% of wastes are discharged into the river. The Tuy River Agency is going to order close those not yet facilitated with treatment plants to stop operations.

Table 1.3-1 compares the water quality before and after the treatment. As shown in the table, more than 90% of BOD and SS and 80-90% of COD are removed. Attention should be paid, however, to the fact that the wastewater from piggeries even after treatment contains a high BOD load, 1,000 mg/l. Table 1.3-2 shows the effect of the removal of solid wastes in the value of BOD. Utilization of solid wastes for fertilizer should be promoted for application of biological recycling system in environmental improvement.

1.3.2 Toxicants

In accordance with interview survey results, 54% of non-food factories have treatment plants. Of the factories with treatment plant, 53% are equipped with physical-chemical treatments, 13% are with separators (including those of removal of solid particles), 7% are with biological treatment, and the remaining 27% have other treatment that includes tank storage.

The results of water quality tests for before and after the treatment of heavy metals is discussed below (see Table 1.3-3):

With regard to Pb, one factory achieved a 47% treatment rate. Other factories are below the measurable limit. The discharge from the factory with the treatment rate of 47% still exceeds the discharge standard to the river, and implies that there is a problem in the plant itself or in maintenance. The wastewater from this factory is discharged to a tributary of the Tuy River, and the concentrations of Cr and Cu also exceed the standard.

The treatment rates of Cr vary widely between 28 and 80%. At two factories, the concentration after the treatment is higher than that before, indicating a possibility of inadequate operation and maintenance.

Also for Zn, the treatment rate varies from 5 to 80%. At three factories, high concentrations were found in water after treatment. The treatment rates for Hg and Ni also have a wide range and high concentrations were found even from the sample after treatment.

1.3.3 Turbid Water

As discussed before, turbid water originates, chiefly, from erosion over the entire basin and sand quarries. Of these, sand quarries are considered as industrial wastewater and the other is natural condition (though the destruction of the basin is due to human activities).

Wastewater from sand quarries is from flushing water. In the case of sand quarries along the Qda. Maitana, 20 to 25 l/sec of water is used. One site is equipped with two sand settling ponds and these are used alternatively. Overflow water from the

settling ponds flows to the river. In the other case, there are no sand settling ponds and high concentrations of suspended solids flow into the Tuy River.

1.3.4 Confirmation of the Influence by Simulation Model

The influence of wastewater from factories and piggeries is examined by the simulation model under the following conditions:

- The RIOS model is applied as the simulation model
- As the water quality index for simulation of organic pollution, BOD is used

According to the calculation results, the influence is identified as follows:

As shown in the table below, the BOD production load in the upper and middle basin of the Tuy River is 73 ton/day and 25 ton/day, respectively. The share of the production in the upper basin is as high as 74%. The discharged load from the basin is almost the same at 20.9 ton/day in the upper basin and 20.6 ton/day in the middle basin. This is because the production load at an alcohol distillery in the upper basin shares a large amount and the treatment at the same factory greatly reduces the discharged load, although the discharge load to the river remains high.) Discharge load in the middle basin is relatively high because of the high share in the mid basin and the low treatment rate of the domestic wastewater.

| Pollution Load | Pollution source | Upper Basin | | Middle Basin | | Total | |
|-----------------|------------------|-------------|------|--------------|------|----------|------|
| | | (kg/day) | (%) | (kg/day) | (%) | (kg/day) | (%) |
| Production Load | Factory | 58,812 | 80.2 | 7,859 | 30.9 | 66,672 | 67.5 |
| | Piggery | 8,554 | 11.7 | 3,758 | 14.8 | 12,312 | 12.5 |
| | Domestic | 5,958 | 8.1 | 13,799 | 54.3 | 19,756 | 20 |
| | Total | 73,324 | 100 | 25,417 | 100 | 98,740 | 100 |
| Effluent Load | Factory | 11,817 | 56.6 | 5,046 | 24.5 | 16,864 | 40.7 |
| | Piggery | 3,222 | 15.4 | 1,878 | 9.1 | 5,100 | 12.3 |
| | Domestic | 5,840 | 28.0 | 13,670 | 66.4 | 19,510 | 47.0 |
| | Total | 20,880 | 100 | 20,594 | 100 | 41,474 | 100 |

In the upper basin, the share of wastewater from factories is high. The discharge load from the alcohol distillery at El Consejo is considerably high. An industrial area in Las Tejerías also discharges a large amount of pollution load in the upper basin. The share of the wastewater from the factories is 80% in production load and 56% in

discharged load. Wastewater from piggeries is 12% in production and 15% in discharge load. The domestic wastewater is only 8% in production load but it increases up to 28% in discharged load because the treatment rate is low.

In the middle basin, the share of the domestic wastewater is as high as 54% in production load and 66% in discharge load. Factories are located in the cities of Cúa, Charallave, Ocumare del Tuy, and share 31% of production load and 25% of discharged load. Piggeries share only 9% of discharge load in the middle basin.

As a whole in the upper and middle basins, the production load of factories is as high as 68%. It decreases to 41% in the discharged load and lower than that of domestic wastewater of 47%. The ratio of wastewater from factories and piggeries in the upper and middle basin is 2:1, the ratio for domestic wastewater is 1:2 in contrast.

The rate of the load that flows into the Tuy River is compared: Many towns are not far from the Tuy River and most discharge load flows into the Tuy River. In contrast, in two tributaries, Qda. Maitana and Qda. Charallave, polluters are relatively far from the Tuy River and the delivery rate to the Tuy River is low.

Self-purification of the river is high in some stretches. The stretch from Qda. Guayas to Táchata, receiving the water of Qda. Maitana, especially presents a high rate of self-purification. In this stretch, BOD concentration is reduced to one tenth. It should be noted that the self-purification is resolution and/or decomposition of organic substances and their deposition on the riverbed, which is not an absolute improvement of the pollution. Such self-purification in the middle stream is also remarkable.

On the whole basin, the total production pollution load is 99 ton/day, discharge load is 41 ton/day, the effluent load flows into the Tuy River is 29 ton/day and the effluent load in the Tuy River at Toma de Agua is 3 ton/day.

2. MASTER PLAN STUDY

2.1 Consideration of Applicable Structure Measures

For the treatment of wastewater from the factories and piggeries, the applicable structure measures in principle is to install treatment plants so as to comply with the water quality standard.

2.2 Measures to Reduce Pollution from Factories and Piggeries

2.2.1 Study Procedure for Factories and Piggeries

To cope with organic pollution problem from factories and piggeries, the applicable structure measure is installation of treatment plant in the factories and piggeries. In principle, the selection of suitable treatment plant and its installation to fulfill the water quality standard are the responsibility of factory and piggery owners. In this Master Plan study, the suitable treatment plant and the necessary cost to install the treatment plants are examined in the following procedure:

- Preparation of an inventory of factories and piggeries
- Identification of installation and treatment conditions of the plant
- Study on the unit cost to treat wastewater from the factories and piggeries
- Blocking the study area to estimate the treatment cost for factories and piggeries
- Cost estimation of the treatment plant to treat the wastewater for existing factories and piggeries
- Cost estimation to install treatment plant for newly built factories.

2.2.2 Investigation of the Installation and Treatment Conditions of Plants

As the inventory of the existing factories and piggeries, factories of 103 and piggeries of 33 are arranged in the list as mentioned in Section 1.1 "Pollution Source Inventory".

From the inventory, 40 factories and 10 piggeries were selected to investigate the installation and treatment condition and examined the unit cost to treat the wastewater from the factories and piggeries so as to fulfill the water quality standard. Fig.2.2-1 shows an example of treatment plant flowchart of factory and piggery. Among them surveyed, 18 factories and 2 piggeries fulfill the water quality standard as shown below:

| Group | Number of Factories (Nos.) | Number of Piggeries (Nos.) |
|--|----------------------------|----------------------------|
| (1) Factories and piggeries which fulfill the water quality standard | 18 | 2 |
| (2) Factories and piggeries which do not fulfill the water quality standard though they have installed a plant | 9 | 5 |
| (3) Factories and piggeries which have not installed a plant | 13 | 3 |
| Total | 40 | 10 |

As the investigation results for the said group (1), the suitable treatment plants are identified. Also, the cost of the suitable treatment plants are examined. The cost of the suitable treatment plants are shown in Fig.2.2-1.

2.2.3 Unit Cost to treat the wastewater from factories and piggeries

For the groups of factories and piggeries which fulfill the standard, the unit cost to remove the effluent pollution load up to the level fulfilling the standard is examined. As a result, the unit cost is obtained as shown below:

| Category (Factory/Piggery) | Average Discharge Wastewater Volume (ton/day) | Average Construction Cost of Treatment Plant (US\$) | Unit Cost (US\$/ton/day) |
|----------------------------|---|---|--------------------------|
| Food Related | 317 | 404,924 | 1,277 |
| Non-Food Related | 106 | 208,724 | 1,963 |
| Piggery | 11.5 | 20,000 | 1,739 |

2.2.4 Blocking the study area to estimate the treatment cost for factories and piggeries

In connection with the study on the sewage treatment plant, the study area is divided into several blocks and the treatment cost for factories and piggeries is calculated for each blocked area. The treatment cost for existing factories and piggeries is US\$ 14,055,000 in total as shown in [Table 2.2.1](#).

2.2.5 Cost to Install Treatment Plants to the Factories Built by 2003

In the future, it is expected that factories will be newly built as discussed in the baseline projection. The number of the factories newly built by 2003 is 44. The cost to install treatment plant to these factories will be US\$ 10,791,000 as shown in [Table 2.2.2](#).

2.2.6 Cost to Install Treatment Plants to the Factories Built by 2010

Furthermore, the necessary cost for the factories newly constructed in the future after 2003 by 2010 is estimated. The number of the factories newly built from 2003 to

| Group | Number of Factories (Nos.) | Number of Piggeries (Nos.) |
|--|----------------------------|----------------------------|
| (1) Factories and piggeries which fulfill the water quality standard | 18 | 2 |
| (2) Factories and piggeries which do not fulfill the water quality standard though they have installed a plant | 9 | 5 |
| (3) Factories and piggeries which have not installed a plant | 13 | 3 |
| Total | 40 | 10 |

As the investigation results for the said group (1), the suitable treatment plants are identified. Also, the cost of the suitable treatment plants are examined. The cost of the suitable treatment plants are shown in Fig.2.2-1.

2.2.3 Unit Cost to treat the wastewater from factories and piggeries

For the groups of factories and piggeries which fulfill the standard, the unit cost to remove the effluent pollution load up to the level fulfilling the standard is examined. As a result, the unit cost is obtained as shown below:

| Category (Factory/Piggery) | Average Discharge Wastewater Volume (ton/day) | Average Construction Cost of Treatment Plant (US\$) | Unit Cost (US\$/ton/day) |
|----------------------------|---|---|--------------------------|
| Food Related | 317 | 404,924 | 1,277 |
| Non-Food Related | 106 | 208,724 | 1,963 |
| Piggery | 11.5 | 20,000 | 1,739 |

2.2.4 Blocking the study area to estimate the treatment cost for factories and piggeries

In connection with the study on the sewage treatment plant, the study area is divided into several blocks and the treatment cost for factories and piggeries is calculated for each blocked area. The treatment cost for existing factories and piggeries is US\$ 14,055,000 in total as shown in [Table 2.2-1](#).

2.2.5 Cost to Install Treatment Plants to the Factories Built by 2003

In the future, it is expected that factories will be newly built as discussed in the baseline projection. The number of the factories newly built by 2003 is 44. The cost to install treatment plant to these factories will be US\$ 10,791,000 as shown in [Table 2.2-2](#).

2.2.6 Cost to Install Treatment Plants to the Factories Built by 2010

Furthermore, the necessary cost for the factories newly constructed in the future after 2003 by 2010 is estimated. The number of the factories newly built from 2003 to

2010 is 120. The cost to install treatment plant to these factories will be US\$ 18,606,000 as shown in **Table 2.2.3**

2.2.7 Cost to Install Treatment Plants to Reduce Odor and Color

As discussed in the key issues, water intake suspension at water intake point occur due to odor and color. The suspension days due to odor and color are 7 days and 6 days (13 days in total), respectively, and suspension hours are 8 hours a day on average. As the target, it is proposed to secure water quantity by reducing the suspension times of water intake through water quality improvement of odor and color, and the reduction volumes are roughly estimated at 403,200 m³ for odor and 345,600 m³ for color assuming that river discharge at the time of suspension is 2 m³/s, namely $2 \times 7 \times 8 / 24 \times 86,400 = 403,200$ and $2 \times 6 \times 8 / 24 \times 86,400 = 345,600$. In short, the effectiveness of water quality improvement by reducing the suspension period of 13 days is the securement of the water quantity of 748,800 m³/year (0.024 m³/s), i.e., 403,200 m³/year (0.013 m³/s) for odor and 345,600 m³/year (0.011 m³/s) for color.

Therefore, it may be possible to reduce the water intake suspension through installation of treatment plant for such the factories discharging the elements of odor and color in an early stage. In this connection, the cost to install treatment plants to those factories is calculated. It is considered that the factories which discharge the elements of odor and color seems to be the industrial category of drink and plastic products according to the interview survey results. The number of these factories are 6 at present. The cost of treatment plant is US\$1,692,000 as shown in **Table 2.2.4**

2.3 Identification of the Priority Area

In this section, the priority area in which the treatment plants of factories and piggeries be introduce in early stage:

(1) Study Cases to Select Priority for Institutional Measures

(a) Blocking of the Study Areas

To select the priority area to apply the institutional measures, alternative study cases are examined by comparing areas in terms of effectiveness to reduce pollution to the target point. For this purpose, the industrial area is divided into several blocks as mentioned in 2.2.4.

2010 is 120. The cost to install treatment plant to these factories will be US\$ 18,606,000 as shown in [Table 2.2-3](#).

2.2.7 Cost to Install Treatment Plants to Reduce Odor and Color

As discussed in the key issues, water intake suspension at water intake point occur due to odor and color. The suspension days due to odor and color are 7 days and 6 days (13 days in total), respectively, and suspension hours are 8 hours a day on average. As the target, it is proposed to secure water quantity by reducing the suspension times of water intake through water quality improvement of odor and color, and the reduction volumes are roughly estimated at 403,200 m³ for odor and 345,600 m³ for color assuming that river discharge at the time of suspension is 2 m³/s, namely $2 \times 7 \times 8 / 24 \times 86,400 = 403,200$ and $2 \times 6 \times 8 / 24 \times 86,400 = 345,600$. In short, the effectiveness of water quality improvement by reducing the suspension period of 13 days is the securement of the water quantity of 748,800 m³/year (0.024 m³/s), i.e., 403,200 m³/year (0.013 m³/s) for odor and 345,600 m³/year (0.011 m³/s) for color.

Therefore, it may be possible to reduce the water intake suspension through installation of treatment plant for such the factories discharging the elements of odor and color in an early stage. In this connection, the cost to install treatment plants to those factories is calculated. It is considered that the factories which discharge the elements of odor and color seems to be the industrial category of drink and plastic products according to the interview survey results. The number of these factories are 6 at present. The cost of treatment plant is US\$1,692,000 as shown in [Table 2.2-4](#).

2.3 Identification of the Priority Area

In this section, the priority area in which the treatment plants of factories and piggeries be introduce in early stage:

- (1) Study Cases to Select Priority for Institutional Measures
 - (a) Blocking of the Study Areas

To select the priority area to apply the institutional measures, alternative study cases are examined by comparing areas in terms of effectiveness to reduce pollution to the target point. For this purpose, the industrial area is divided into several blocks as mentioned in 2.2.4.

(Year: 1995)

| Tuy River | Name of Block | Major Urban Center | No. of Factories | No. of Piggeries |
|---------------|-----------------|-----------------------------|------------------|------------------|
| Upper Stream | El Consejo | El Consejo | 2 | 0 |
| | Las Tejerías | Las Tejerías (Morocopo) | 22 | 11 |
| | Qda. Guayas | Qda. Guayas (Boca de Cagua) | 2 | 9 |
| | Paracotos | Paracotos | 9 | 0 |
| | Río Guare | Tácata | 0 | 1 |
| Middle Stream | Cúa | Cúa | 4 | 1 |
| | Charallave | Charallave | 6 | 3 |
| | Ocumare del Tuy | Ocumare del Tuy | 6 | 3 |
| | S. F. de Yare | S. F. de Yare | 11 | 3 |

(b) Study Cases to Decide Priority Based on Size of Factory and Piggery

In line with the selection of priority areas, it is necessary to examine the economic advantages based on the size of factory and piggery, i.e., whether (1) priority is given to large sized factories and piggeries, or (2) priority is given to middle and small sized factories and piggeries.

In this study, the level of advantage is confirmed by comparing the unit water treatment cost by factory size.

(2) Study on Effectiveness of Each Block to Reduce Organic Pollution

The effectiveness of each blocked area to reduce organic pollution is calculated by using the RIOS model. On the other hand, the cost of treatment plant to reduce the pollution is calculated based on the interview survey results. The effectiveness and cost including economic priority are summarized in Table 2.3-1. As noted from the table, the area of highest priority regarding the installation of a treatment plant is Ocumare del Tuy, followed by El Consejo. The relation between the effectiveness and cost based on economic priority is shown in Fig. 2.3-1 and 2.3-2.

(3) Priority of Each Block

Based on the study results, the areas near the target points will effectively contribute to the reduction of organic pollution in general. The priorities according to the blocked areas are as follows:

| Priority | Blocked Area |
|----------|-----------------|
| 1st | Ocumare del Tuy |
| 2nd | El Consejo |
| 3rd | S. F. de Yare |
| 4th | Cúa |

| Priority | Blocked Area |
|----------|--------------|
| 5th | Charallave |
| 6th | Qda. Guayas |
| 7th | Las Tejerías |
| 8th | Paracotos |

To reduce odor and color which cause suspension of water intake, high priority is given to factories discharging pollution that is likely to affect the color and odor in the whole Study Area.

(4) Study on Effectiveness of Size of Factory and Piggery to Reduce Organic Pollution

To examine the effectiveness of size of factories and piggeries to the reduction of organic pollution, the unit water treatment cost is calculated based on the observed data.

Fig. 2.3-3 shows the unit water treatment cost for treatment plants and the water treatment volume. As noted, the decrease in the initial cost per unit treated (Bs/m³) is inversely proportional to the volume treated. Thus, from the economic viewpoint the priority to provide a treatment plant is given to large sized factories and piggeries. Judging from the present sizes of factories and piggeries, factories with more than 300 employees and piggeries with more than 5,000 pigs belong to the large size group. (Refer to Table 2.3-2.)

3. FEASIBILITY STUDY ON INSTALLATION OF TREATMENT PLANTS TO FACTORIES AND PIGGERIES

3.1 General

In the Master Plan study, an inventory of factories and piggeries was prepared based on the following information: (1) OCEI census in 1990, (2) list of factories and piggeries enrolled in the Tuy Agency and (3) other information through field investigation. Eventually, an inventory of 103 factories and 33 piggeries was arranged classifying by industry categories and their locations. The inventory includes number of employees (refer to Table 1.1-1).

In this feasibility study, installation condition of a treatment plant in each factory and piggery is re-examined to identify the following points: (1) percentage of factories and piggeries with a wastewater treatment plant, (2) percentage of factories and piggeries which fulfill the water quality standard for wastewater discharged, (3) basic process of planned treatment plants and (4) cost to install and maintain a treatment plant.

Based on the above information, the factories and piggeries are broadly classified into several groups, to which similar wastewater treatment processes can be applied. For each group, a standard treatment plant to fulfill the water quality standard is examined together with the necessary cost for its installation and maintenance.

Then the cost to install the wastewater treatment plant for each factory and piggery, which does not satisfy the water quality standard at present, is roughly estimated based on that of a standard treatment plant. Also a necessary cost to install wastewater treatment plants for factories built in the future by 2003 is estimated. These costs are required to promote the measures for treatment of wastewater from the factories and piggeries. The costs are shouldered by the factory and piggery owners. Also the costs are used for the formulation of the proposed environmental fund, which is used when the factory and piggery owners face the financial constraint to install the treatment plants.

3.2 Installation Condition of Treatment Plant

To investigate the installation conditions of a treatment plant, 38 factories out of 103 and 10 piggeries out of 13 in the inventory were selected at random, in addition to 27 factories and 3 piggeries investigated in the Master Plan study stage. As a result of the investigation for 65 factories and 13 piggeries, the following conditions were clarified:

- (1) The installation condition of factories and piggeries is broadly divided into three cases: (1) those which satisfy the water quality standard, (2) those which do not satisfy the standard though they have installed a treatment plant, and (3) those which have not installed a treatment plant (refer to Table 3.2-1).

The three cases are as follows:

| Case | Number of Factories(Nos.) | Percentage (%) |
|--|---------------------------|----------------|
| Factories which satisfy the water quality standard | 25 | 38 |
| Factories which do not satisfy the standard though they have installed a plant | 5 | 8 |
| Factories which have not installed a plant | 35 | 54 |
| Piggeries which satisfy the water quality standard | 2 | 15 |
| Piggeries which do not satisfy the standard though they have installed a plant | 8 | 62 |
| Piggeries which have not installed a plant | 3 | 23 |

(2) The treatment plants in the factories and piggeries at present can be broadly classified in the following processes:

- (a) Biological treatment process to reduce high concentration of bio-organic substances which are easily resolved.
- (b) Biological followed by physical-chemical treatment process to reduce medium concentration of bio-organic substances.
- (c) Physical-chemical treatment process to reduce chemical and organic substances which are difficult to be resolved.
- (d) Physical-chemical followed by biological treatment process to reduce metals and organic substances.
- (e) Physical-chemical treatment process to reduce metals
- (f) Physical-chemical treatment process to reduce non-organic suspended solids (SS)
- (g) Biological treatment process to reduce high concentration of bio-organic substances which are easily resolved.

In general, the above treatment processes are applied to the following categories of the industries and the installation cost are as shown in the following table(see Tables 3.2-2, -3 and -4):

| Process | Category of industries | Number of * Factories and Piggeries by Categories | Installation Costs (US\$ thousand) | | |
|---------|---------------------------|--|-------------------------------------|------------------------------|--------------------------|
| | | | Large Scale Factories | Middle Scale Factories | Small Scale Factories |
| (a) | Food Product Industries | 6 | 345 - 1,002 | 104 | 64 - 117 |
| (b) | Manufacturing of Textiles | 4 | 390 - 420 | no data | 132-160 |
| (c) | Chemical Industry | 6 | 267 -465 | 82 -200 | 30 -76 |
| (d) | Tannery | 3 | no data | no data | 47 |
| (e) | Metal manufacturing | 7 | 156 | 40 - 175 | 31 - 122 |
| (f) | Sand quarries | 3 | no data | no data | 15 |
| (g) | Piggeries | 13 | no data | 1.2-28 | no data |

*Among factories and piggeries surveyed, only those which satisfy the water quality standard

As for the operation and maintenance cost, the following percentage to installation cost is obtained:

| Process | Category of industries | O&M cost (%) |
|---------|---------------------------|--------------|
| (a) | Food Product Industries | 2.85 |
| (b) | Manufacturing of Textiles | 4.98 |
| (c) | Chemical Industry | 5.87 |
| (d) | Tannery | 5.10 |
| (e) | Metal manufacturing | 5.50 |
| (f) | Sand quarries | 5.20 |
| (g) | Piggeries | 5.20 |

3.3 Study on Standard Treatment Processes

Based on the above present installation condition of treatment plants, standard treatment processes for several cases are examined to estimate cost for installation of treatment plants.

Classification of Industries to examine Standard Treatment Process

As identified through the investigation, treatment processes for the present factories and piggeries are broadly classified into seven (7) cases. In this connection, the standard treatment processes are examined for the same 7 cases based on the specification shown in Table 3.3-1.

(1) Biological treatment which applies to (a) food product industries

Biological treatment is used to reduce the high concentration (BOD_{2,000} -

4,000mg/l) of bio-organic substances, mainly produced by food factories. A typical biological treatment process is the activated sludge process with extended aeration.

Configuration of treatment process: a screen tank, an aeration tank, a sedimentation tank and a chlorination tank. A primary sedimentation tank is not necessary because of few solid.

The standard treatment process of this type of treatment plant is shown in Table 3.3-2(1/7).

(2) Biological followed by Physical-chemical treatment which applies to (b) manufacturing of textile

This treatment is used to reduce medium concentration of bio-organic substances, mainly produced by the textile industries. Generally, a standard activated sludge method is adequate. Since BOD load is medium, primary sedimentation is effective. The pH is not neutral and thus, neutralization as pretreatment is required.

Configuration of treatment tanks: a screen, neutralization, primary sedimentation, aeration, final sedimentation and chlorination.

The standard treatment process of this type of treatment plant is shown in Table 3.3-2(2/7).

(3) Physical-chemical treatment which applies to (c) chemical industry

In chemical industry, the substances such as oil based chemical, paints and synthetic resins are mainly produced. Physical-chemical treatment method is appropriate for this sewage due to biodegradable organic compounds; a storage tank is effective for flow equalization and reduction of high SS, followed by flocculation.

Configuration of treatment tanks: a screen, storage, neutralization, flocculation, chemical conditioning, sedimentation. Storage and sedimentation tanks have to enable long time treatment processes of long duration.

The standard treatment process of this type of treatment plant is shown in Table 3.3-2(3/7).

(4) Physical-chemical followed by biological treatment which applies to Tannery

This treatment process is used to reduce metals and organic substances which are mainly produced in the tannery industry. Treatment for both organic substances and chromium is required; A special treatment is to reduce the valency of chromium from 6+ to 3+, followed by neutralization, flocculation and biological process (activated sludge method).

Configuration of treatment tanks: chemical reduction, neutralization, flocculation, sedimentation for chromium treatment. The other combination for organic substances is one for those of aeration, sedimentation and chlorination.

This is the general recommended configuration for tanneries, though, it should be warned that local factors in sewage characteristics may modify this recommendation.

The standard treatment process of this type of treatment plant is shown in Table 3.3-2(4/7).

(5) Physical-chemical treatment process which applies to (e) metal manufacturing

This treatment process is used to remove metals which are mainly produced from metal manufacturing industries. Flocculation treatment by neutralization is appropriate for removal of such heavy metals.

Configuration of treatment tanks: storage, neutralization, flocculation, sedimentation. Two types of sediments are collected; One is suspended type in storage tank and flocculate by neutralization.

The standard treatment process of this type of treatment plant is shown in Table 3.3-2(5/7).

(6) Physical-chemical treatment process which applies to (f) sand quarries

This treatment process is used to remove inorganic suspended solids (SS) which are mainly produced from sand quarry industries. Natural sedimentation cannot achieve the limitation that SS should be below 80 mg/l; Flocculate aid is applied to remove it.

Combination of treatment tanks: flow equalization, chemical conditioning and sedimentation.

The standard treatment process of this type of treatment plant is shown in Table 3.3-2 (6/7).

(7) Biological treatment which applies to piggeries

Biological treatment is in general as same as that for food product industries used. A typical biological treatment process is the activated sludge process with extended aeration.

Configuration of treatment process: a screen tank, an aeration tank, a sedimentation tank and a chlorination tank. A primary sedimentation tank is not necessary because of few solid.

The standard treatment process of this type of treatment plant is shown in Table 3.3-2 (7/7).

Cost Estimation for Standard Treatment Plant

Based on the standard treatment process, the costs for standard treatment plants for the seven cases are estimated assuming the scale of the factories and piggeries in three cases : (1) large scale factory and piggery, (2) medium scale factory and piggery and (3) small scale factory and piggery. The scale of the factories and piggeries are expressed by the discharge volume of factories and piggeries.

Table 3.3-3 shows the unit cost of standard treatment plants.

Fig. 3.3-1 shows the relation between cost and discharge volume of waste water according to interviews and the cost estimation for standard treatment plants. As noticed from these figures, the cost of standard treatment plant approximately coincides with average value of actual costs of treatment plants obtained from interviews.

3.4 Cost Estimate for Installation of Treatment Plant for Existing Factories

Based on the costs of standard treatment plants, the cost for installation of treatment plants for existing factories and piggeries can be estimated multiplying the cost of a standard treatment plant by the number of the existing factories. Since the factories meeting the water quality standard do not need to install a new treatment plants, the cost estimation is made only for the factories which do not fulfill the water quality standard.

As mentioned earlier, among the existing factories and piggeries with treatment plant, the percentage of which do not fulfill the water quality standard are 8% and 6%, and the percentage of factories and piggeries which do not have treatment plants are 54% and 59%, respectively.

In this connection, the cost for installation of treatment plants for existing factories and piggeries is calculated in the following manner;

- For the factories with treatment plants not fulfilling the water quality standard, 50% of the standard treatment plant cost is adopted considering their scale.
- For the factories with no treatment plant, 100% of the standard treatment plant cost considering the scale of the factories is adopted.
- O&M cost is calculated multiplying the said percentage of O&M cost by the installation cost.

The total costs for installation of treatment plants for existing factories and piggeries are US\$ 11,597,900 and US\$1,253,900, while annual O&M costs are US\$519,000 and US\$65,203. Tables 3.4-1 and 3.4-2 show the cost estimation.

3.5 Cost Estimate for Factories newly Constructed by 2003

The number of factories newly constructed in the basin is estimated in the Master Plan Study. Based on the number of factories by industrial categories, the total cost and annual O&M cost necessary for treatment plants for those newly constructed are

estimated at US\$ 9,038,000 and US\$401,000. The cost estimation is shown in Tables 3.5-1 and 3.5-2.

Table 3.5-2 Operation & Maintenance Cost of Newly Built Factories by 2003

| Industry | Construction Cost (i...j) | Rate of O/M Cost in Construction Cost (%) | Annual O/M Cost (\$/year) |
|--------------------------|---------------------------|---|---------------------------|
| Food Production | 3,351,700 | 2.85 | 95,523 |
| Manufacturing of Textile | 1,282,000 | 4.98 | 63,844 |
| Chemical & others | 2,110,800 | 5.87 | 123,904 |
| Metal Manufacturing | 1,995,500 | 5.10 | 101,771 |
| Tannery | 230,000 | 5.50 | 12,650 |
| Sand Quarries | 68,000 | 5.20 | 3,536 |
| Piggery | . | . | . |
| Total | . | . | 401,228 |
