
Sample No. : 95-EP-03
Location : Zhezkazgan South Mine
Ore type : Cu Ore
Minerals :
Cc : chalcocite
Bo : bornite
Cv : covellite

Appendix 12-1 Geological Logging of the Drill Hole "MJK-1"(1/10), Zhaman-Aibat Ore Deposit

MJK - I

AREA: ZHAMAN-AIBAT INCLINATION: -90° BEARING: — ELEVATION: 357.04m FINAL DEPTH: 650.50m

DEPTH (m)	DESCRIPTION	REMARKS	MINERALIZATION
1.20	Strongly weathered rock with fragments of red siltstone and fine-grained sandstone. Content of fragments is up to 50%		
6.00	Reddish brown weathered siltstone with unclearly expressed bedded structure, partially fractured. Leached caverns are partly filled in by calcite. Interlayer: Grayish-red weathered, fine-grained, sandstone at the depth of 1.40 m with thickness, equal to 30 cm.	∠5°	
17.60	Reddish brown siltstone with fine grained, partially porous sandstone. Lamination angle is equal to 5°. These rocks are strongly fractured. Fractures surface is coated by gypsum, traces of iron oxide and dendrite of manganese. Leached caverns are sizing up to 0.5x1.5 cm, filled in by calcite	∠5°	
21.40	Light reddish brown fine grained sandstone. Interlayers of red coarse-grained sandstone (5-20 cm thick) with clayey-carbonate-ferrous cement is strongly weathered. This sandstone is sometimes porous, unclearly expresses bedded structure. Gravels included in sandstone orient at 5°.	∠5°	
39.05	Reddish brown, sandy siltstone, unclearly expressed bedded structure, strongly fractured. Traces of ferruginization, manganese dendrite and thin films of gypsum and chlorite at walls of fractures. Lamination angle is equal to 5°. Leached caverns filled in by calcite are described all through the horizon sizing up to 2.0 x 2.0 cm. Numerous layers of gypsum (selenite) are observed below 28.6 m with thickness 0.1-1.0 cm, oriented at 5-10° (partly 35-60°).	∠5°	23.9-26.2m weakly argillized
47.90	39.05-44.8m, 46.1-47.9m. Light reddish brown fine-grained sandstone with carbonate-clayey cement including interlayers of kaolinized coarse-grained sandstone layers up to 8 cm, express lenticular and horizontally-bedded structure due to red fine-grained sandstone interlayers (0.2m). There are numerous interlayers of fiber-like gypsum with thickness from 2 to 4, oriented at 5-0°. 44.8-46.1m Granule-pebble conglomerates, composed by quartz, limestone, flintstone with fragments of red aleurosandstone from 0.5 x 2 cm to 2 x 4 cm in amount up to 30%. The gravels and flat fragments are shaped as lamination oriented at 5°.	∠5°	
66.90	Reddish brown siltstone (or fine-grained muddy sandstone) with carbonate ferrous cement. Partially brecciated, sliding surfaces and chlorite films are observed along the fractures. Muddy sandstone has an horizontally bedded structure at 5° due to interlayers of tiny sandstone. The thickness of the tiny sandstone layers is from 10 to 30 cm and maximum thickness is 1.8 m. rocks fractures are filled in by fiber-like gypsum with thickness from 1 to 3 cm, oriented mostly at 5°. 65.65-65.85m Brecciated, chloritization weak	∠5°, ∠5-10°, ∠5°, ∠5°, ∠10°	65.65-65.85m, Brecciated, chloritization weak

Formation: Zaidelisai Formation (Gypsum - rich Red Siltstone)

Appendix 12-3 Geological Logging of the Drill Hole "MJK-1" (3/10), Zhaman-Aibat Ore Deposit

MJK - 1

INCLINATION: -90°

AREA: ZHAMAN-AIBAT BEARING: —

ELEVATION: 357.04m FINAL DEPTH: 650.50m

SCALE (m)	COLUMN	DEPTH (m)	DESCRIPTION	REMARKS	MINERALIZATION	SULFIDE	SILICA	CLAY	CARBONATE	SULFATE	SAMPLE No.	ROCK PROPERTY: Angle of Fliss. (°)	ROCK PROPERTY: No. of Fliss. (/m)	ROCK PROPERTY: Core Rec. %
150			Reddish brown colored siltstone with banded and spotted structure due to the interlayers of tiny sandstone. Partings with thickness from 1 to 3 cm and interlayers of fine-grained sandstone are described at intervals 145.40-145.70 m, 147.3-147.6, 148.2-148.6, 156.9-157.20 m. Graded bedding structure (inclination: 10-15°) is observed in the above intervals. The rock is medium fractured, fractures are filled in by gypsum and are oriented at 5°, 45° and 15°, thickness of gypsum layers varying from 1 mm to 2 cm. Contact with underlying horizon is gradual.	∠ 10° ~ 5°										
		159.00	Brown sandstone, fine grained, with carbonate-ferrous cement. Structure is horizontally bedded at 5° due to interlaying with red colored siltstone. The rock is medium fractured, fractures are filled in by gypsum. Contact with underlying horizon is gradual.	∠ 5°	156.50-156.55m, weakly argillized									
160		160.50												
			Reddish brown, siltstone. Structure is basically horizontally-bedded at 5° due to partings of fine grained sandstone with thickness up to 1 cm, interlayers of red fine-grained sandstone with thickness 10-15 cm occur all through the layer. Interlayer of medium grained sandstone with thickness 33.6m is described at the depth 165.0m and 165.5m.	∠ 5°										
170														
		174.20	Red sandstone, fine grained, with carbonate-ferrous cement. Structure is horizontally bedded at 5° due to the graded bedding structure. Interlayer of siltstone with thickness 33 cm. The rock is medium fractured, fractures are filled in by gypsum with thickness up to 2 cm. Contact with underlying horizon is at 0°.	∠ 0°										
		175.10		∠ 0°										
180			Brown massive siltstone. Unclearly expressed bedded structure. Rare partings of fine-grained sandstone with thickness up to 5 cm and interlayers up to 25 cm. The rock is medium fractured, fractures are filled in by gypsum with thickness up to 3 cm, oriented at 10° and 30°. The layer is continued below.	∠ 10° ~ 30°										
190														
		200.60	200.00-208.65m. Brown colored massive siltstone. Unclearly expressed bedded structure. The rock is medium fractured. Frequent veinlets of gypsum with thickness up to 1 cm. Fractures are oriented at 45°, 15° and 5°. Gypsum veinlets at the interval from to 207.5 to 208.65 m are oriented by two groups (at 15° and 5° and along core axis). Contact with underlying horizon is at 5°.	∠ 5°										
200			208.70-209.15m. Greyish-green siltstone. Horizontally bedded structure resulted from partings of red siltstone with thickness up to 1 cm. The rock is medium fractured, fractures are filled in by gypsum with thickness up to 2 cm. Contact with underlying horizon is at 10°.	∠ 10°										
		208.70	209.15-210.0m. Brown sandstone, fine-grained, with carbonate ferrous cement. Structure is sometimes bedded at 10°, 5° due to fine lamination with siltstone. The rock is medium fractured, fractures are filled in by gypsum and are oriented at 30°, 10°, their thickness varies from 1 mm to 2 cm. Contact with underlying horizon is clear, at the angle 0°.	∠ 0°

290		287.40	Brown, massive siltstone with unclearly bedded structure. Films of gypsum at fractures with thickness 1 mm, oriented at 55°,45°. At the bottom of layer, the rock is strongly fractured (282.9-287.40 m). Contact is at 15°. Thin layers of green-dark green colored siltstone are observed within the interval from 286m to 287.20m												
			Light-red colored, fine-grained sandstone, with carbonate-ferrous cement, cross-bedded at 5-15° due to partings of dark-red siltstone interlayers of dark-red siltstone with total thickness 0.6 m are observed as well. The rock is slightly fractured, fractures are filled in by gypsum. Contact with underlying horizon is at 0°.												
		291.40												
300			Brown siltstone with unclearly bedded structure including the interlayers of fine grained sandstone with thickness up to 30 cm, maximum thickness reaching 0.8 m. These rocks are fractured, fractures are filled in by gypsum (up to 1 mm thick). Contact with underlying horizon is at 0°. Thin layers of green-dark green colored siltstone are observed within the interval from 312.90m to 313.10m	Zhideli(as) Formation (Red Siltstone)										
310		316.60	Red colored fine-grained sandstone with carbonate-ferrous cement. Structure is horizontally bedded at the angle 5° due to partings of dark-red siltstone, thickness of partings reaching 1 cm. Contact with underlying horizon is at 0°.												
		319.70												
320		320.20	Light green colored siltstone												
		323.90	Red, massive siltstone with unclearly bedded structure including interlayers of fine-grained sandstone. Contact with underlying horizon is gradual.												
330		329.90	Alternation of dark-red siltstone and fine-grained sandstone. Siltstone layers are dominant. Fine-grained sandstone layers occur at the intervals 324.0-324.4, 325.3-325.55, 328.1-328.4, 329.3-329.6 m. Structure is horizontally-bedded at the angle 5°. Fractures are filled in by gypsum films												
		332.40	Alternation of dark-red siltstone and fine grained sandstone. Sandstone layers are dominant. Sandstone layers are light-red colored, and matrix is composed of carbonate-ferrous cement. Bedding structure (due to interlaying with siltstone) is horizontally-bedded at the angle 5°. Stretched-shaped fragments of red aleurolite 0.3 x 1.0 cm in size occur at the bottom of the Sandstone layer. Contact with underlying horizon is clear at 15° as to core axis.												
340			Brown, sandy siltstone with frequent interlayers of fine-grained sandstone with thickness 10-15 cm with lamination at 15-10°. The rock is medium fractured, fractures are filled in by gypsum, its thickness varying from fiber-like to 1 mm, they are oriented at 5-15°. Contact with underlying horizon is gradual.												
		349.30	Light-red colored fine-grained sandstone with carbonate-ferrous cement. Sedimentary structure [due to partings of dark-red, fine-grained siltstone] is cross-bedded at 65°, 0°, 10°. The rock is slightly fractured. Interlayers of dark-red sandstone are also described here. Contact with underlying horizon is clear at 0°.

Appendix 12-6 Geological Logging of the Drill Hole "MJK - 1" (6/10), Zhaman-Aibat Ore Deposit

MJK - 1

AREA: ZHAMAN-AIBAT INCLINATION: -90° BEARING: — ELEVATION: 357.04m FINAL DEPTH: 650.50m

DEPTH (m)	DESCRIPTION	REMARKS	MINERALIZATION
	Dark-reddish brown, sandy siltstone with potted / bedded structure due to interlaying with fine-grained sandstone. Interlayers of fine-grained sandstone show cross-bedded structure (thickness 15-25 cm). The rock is slightly fractured, fractures contain gypsum with thickness 5 mm.		
356.45 – 358.70	Reddish brown, sandstone, medium-grained, sometimes coarse-grained, with carbonate ferrous cement. Graded bedding structure and cross-bedding structure are observed (at the angle 10-20°, 5°). Frequent accumulations of anhydrite / gypsum sizing up to 1.0 x 0.8 cm are described within the interval from 356.65 to 356.95 m. Fragments of red siltstone are described at the bottom of the layer with size up to 0.2 x 0.5 m. Contact with underlying horizon is clear at 5°. Gypsum interlayer (1 cm thick) is occurred at the contact.	∠5°-20°, ∠5°	
– 365.50	Dark-gray, sandy siltstone with potted and lenticular-bedded structure due to interlayers and spots of light fine-grained limy sandstone. Interlayers of fine-grained sandstone with thickness 18 cm are also observed. Contact with underlying horizon is gradual.		
– 369.95	Reddish brown, fine-grained sandstone with carbonate-ferrous cement. Structure is horizontally-bedded, sometimes cross-bedded at the angle 10-15° due to partings of fine-grained sandstone with darker shading with thickness of the partings equal to 0.1 mm. Partings of dark-red siltstone with thickness up to 3 cm. Accumulations of anhydrite (1.0 x 1.5 cm) are also observed there. The rock is slightly fractured, fractures are coated by gypsum film. Contact with underlying horizon is at 0°. Interlayer of intraformational conglomerate (8 cm thick) at the contact.	∠0°, ∠5°-10°	
– 379.70	Red, sandy siltstone, horizontal bedding, including interlayers of limy fine-grained sandstone with thickness up to 10 cm. The rock is fractured. Contact with underlying horizon is at the angle 5°. 371.6-372.1m, Red, fine-grained sandstone with carbonate-ferrous cement including interlayers of siltstone. Cross-bedded structure at the angle 5-10°.	∠5°	
– 397.65	**Sandstone layers:** Reddish brown, fine-medium grained sandstone, with carbonate-ferrous cement, fine interlaying with fine grained sandstone (0.2cm thick), cross-bedded at the angle 15-10°. The rock is slightly fractured, filled in by gypsum films. Contact with underlying horizon is wavy. 397.15-397.85m: Grayish-red, fine-grained laminated sandstone with siliceous-carbonate ferrous cement. **Siltstone layers:** Reddish brown, sandy siltstone or aleurosandstone, including interlayers of light limy fine-grained sandstone with thickness 3-5 cm, horizontally-bedded. Contact with underlying horizon is sharp at the angle 0°.	∠0°-15°, ∠0°	397.15-397.85m. Weakly silicified
	Reddish brown, sandy siltstone including spots of light-red limy sandstone and rare spots of green aleurolite. Interlayer of greenish-gray fine-grained sandstone with thickness 25 cm occur at the depth 403.2 m; Thin interlayers of grey colored fine-grained sandstone with thickness 20 cm are observed at the interval from 413 to 419m. Contact with underlying horizon is gradual.		403.20m. Appearance of gray sandstone
– 415.75	Reddish-gray, fine-grained sandstone with siliceous-carbonate-ferrous cement, horizontally-bedded at 5°. Sometimes transforming into medium-coarse-grained sandstone. Partings of greenish-gray aleurolite with thickness 3-5 cm, interlayer of red aleurolite with thickness 20 cm are observed as well. Fragments of dark-red aleurolites. Contact is with underlying horizon is gradual.		
– 417.60	Reddish brown, sandy siltstone, spotted-bedded structure due to interlaying with fine grained sandstone. Contact with underlying horizon is unclearly expressed, oriented at the angle 0°.	∠0°	415.75-417.60m. Weakly disseminated by pyrite. Weakly silicified
– 420		∠0°	419.80m-420.00m. Weakly disseminated by pyrite. Pyrite grains are very fine

REMARKS: Zhezkazgan Formation (Gray Sandstone)

DESCRIPTION	Angle
Reddish brown, sandy siltstone, massive with lamination due to interlaying with gray fine-grained sandstone. Interlayer of reddish-gray fine-grained sandstone occurs at the interval 421.3-421.75. Contact with underlying horizon is clear at the angle 5°.	
Gray medium-fine grained sandstone with siliceous-carbonate-ferrous cement. Interlayer of gray aleurolite with thickness 10 cm, fragments of dark-gray aleurolite 0.5 x 1.0 cm are observed as well. Contact with underlying horizon is clear at the angle 0°.	∠0°, ∠0°
Reddish brown siltstone with gray spots with interlayers of fine-grained sandstone with thickness 20 cm. Bedding structure is horizontal. Contact with underlying layer is gradual.	∠0°
Gray sandstone with red spots, fine-grained, with siliceous-carbonate cement. Bedding structure is horizontal, cross-bedded at the angle 5-10°. The rock is slightly fractured, with films of calcite at fractures. Contact with underlying layer is unclear at the angle 0°.	∠0°-10°
Reddish brown, sandy siltstone, including "sandstone balls (2-4cm)" and thin layers of sandstone. Interlayer of grayish-red fine-grained sandstone with thickness 16 cm occurs at the depth 437.55 m. Contact with underlying layer shows load casting structure (wavy).	∠0°
Dark greenish gray, sandy siltstone, horizontally bedded at the angle 5°. With lamination structure due to interlayers of sandstone. Contact with underlying layer is gradual.	∠5°-10°
Light-gray, coarse-fine-grained sandstone with siliceous-carbonate cement, with calcite films coating fractures. Graded bedding structure is developed at the angles 3°, 10°. Contact with underlying layer is gradual. Frequent very fine grained pyrite crystals occurring at the rock mass.	
Reddish brown, sandy siltstone	
445.50-449.00m. Dark-gray, laminated medium-grained sandstone with siliceous-carbonate cement, with siltstone thin layers. There are a lot of fragments of greenish-gray aleurolite with size up to 3 x 5 cm. Frequent small pyrite crystals occur in the rock mass. 449.00-451.90m. Black-dark gray, siltstone with the bedding structure due to the fine lamination of fine-grained sandstone layers. Joints are oriented at the angle 15-20, 60°. Contact with underlying layer is at the angle 0°. Frequent small pyrite crystals described in the rock mass.	∠0°
Gray, medium grained sandstone with siliceous-carbonate cement, with partings of dark-gray aleurolite with thickness 1-3 cm, and with fragments of dark-gray aleurolite sizing from 0.5 x 1.5 cm to 3 x 4 cm.	
Dark gray-black, sandy siltstone, with the bedding structure at the angle 5° due to partings of fine-grained sandstone. Joints are coated with calcite films, joints are oriented at the angle 5°, sometimes at the angle 45°. Contact with underlying layer is gradual. 459.10-460.45m. Light-gray, fine grained sandstone with siliceous-carbonate cement.	∠5°
Gray-Light gray, coarse-medium grained laminated sandstone, with siliceous-carbonate cement, horizontally bedded, including a lot of thin interlayers of black siltstone with thickness up to 1 mm. The rock is slightly fractured with calcite films coating joints. Interlayer of greenish-gray aleurolite occurs in the interval 470.7-470.85. The rock is slightly fractured. Contact with underlying layer is at the angle 10°.	∠0°, ∠0°
Greenish gray-dark gray, siltstone, including lenses of gray fine-grained sandstone. Joints oriented at the angle 60-55°, calcite films coating joints. Contact with underlying layer is gradual.	
Brown, Alternation beds of Bituminous sandstone (with siliceous-carbonate cement) and siltstone. Interlayer of greenish-gray colored fine-grained sandstone occurs in the interval 484.15-484.3m. A lot of oil saturation zones are described in the interval 484.0-491.0m.	∠0°

MINERALIZATION

- 426.65-428.40m. Pyrite accumulations with size up to 0.4-0.8 cm, and weakly disseminated by pyrite through the layer. Weak silicification
- 430.00-432.25m. Calcite films
- 438.80-440.70m. Weakly disseminated by pyrite.
- 440.7-442.0m, 442.4-443.2m. Disseminated by pyrite. Weak silicification
- 445.50-451.90m. Disseminated by pyrite
  - 446.5-447.7m: weak
  - 447.7-448.2m: strong
  - 449.2-451.9m: weak
- 451.90-454.60m. Weakly disseminated by pyrite
- 454.60-464.80m. Weakly disseminated by pyrite
- 459.0-459.6m. Medium strongly
- 464.80-474.80m. Weakly disseminated by pyrite
- 473.7-475.0m. Strongly disseminated by pyrite
- 474.8-480m. Weak Chloritization
- 480-483.7m. Disseminated by pyrite
- 484.0-491.0m. Appear Bituminous sandstone
- 487.4-489.0m. weakly disseminated by pyrite

SCALE (m)	COLUMN	DEPTH (m)	DESCRIPTION	REMARKS	MINERALIZATION	SULFIDE	SILICA	CLAY	CARBONATE	SULFATE	SAMPLE No.	ROCK PROPERTY: Angle of Fissure (°)	No. of Fissure (/m)	Core Rec. %
500		491.90	Gray, fine-grained sandstone with siliceous-carbonate cement. Accumulation of pyrite crystals observed at the interval 490.35-490.4m. Oil saturation in the interval 490.2-490.9m. The rock is slightly fractured, calcite films at fractures. Contact with underlying layer is at the angle 5°.	∠5°	490.2-490.9m. Appear Bituminous sandstone 490.20-496.10m. Disseminated by pyrite						55 490.0m ~ 490.5m		0	97
		493.20											0	97
		495.10	Dark-gray, siltstone with laminated and thinly bedded sandstone	∠15°									0	97
			Gray, fine-grained sandstone with siliceous-carbonate cement, cross-bedded at the angles 15. Spots with increased pyrite content are also described through the layer, with calcite films coating joints, joints		495.10-499.45m. Weak Chloritization Very weak pyrite dissemination						56	∠70°	1	97
		499.45	Dark-gray, siltstone, with thinly bedded sandstone, at the angle 5°, including spots of light-grey tiny sandstone. Joints contain calcite films. Contact with underlying layer is gradual	∠5°	499.45-502.90m. Weakly disseminated by pyrite Veinlets of calcite						57 500.0m ~ 500.5m		0	97
		502.90		∠5°									0	97
			Gray fine-grained sandstone with siliceous-carbonate cement, with thinly and horizontally bedded siltstone. Interlayer of intraformational conglomerate is observed within the interval 500.8-500.86. Calcite films coating joints and veinlets of calcite 4 cm thick is observed at the bottom of the layer.		502.9-505.0m. Weakly disseminated by pyrite 502.9-506.1m. Weak Chloritization 505.0-505.3m. Cu mineralization, Cu 12%, Ag 72.9 g/t						58 530.0m ~ 530.5m		0	97
		509.40	Greenish-grey-Dark-gray, fine-grained sandstone with siliceous-carbonate cement with horizontally and thinly bedded siltsrosandstone. The rock is slightly fractured with calcite films coating joints. Contact with underlying layer is 0°.	∠0°							59 510.0m ~ 510.5m		0	97
			Greenish-gray - dark gray, sandy siltstone. Structure is bedded at the angle 0-5° due to fine lamination with dark grey sandstone. Contact with underlying layer is gradual. Rare concretions of pyrite with size 1 x 1 - 1.5 - 2.0 cm are described through the layer.	∠0° 0°									0	97
		521.70	Gray-greenish gray, fine-medium grained sandstone with thinly and horizontally bedded red green colored shade with siliceous-carbonate cement. Concretions of pyrite are observed within the layer. The rock is medium fractured with calcite films coating joints.	∠0°	515.8-516.2m, 519.3-525.0m, Weakly disseminated by pyrite 521.70-524.60m. Disseminated by pyrite						60 520.0m ~ 520.5m		0	97
		524.60											0	97
			Gray, sandy siltstone. Interlayer of horizontal micro-crystalline limestone is observed within the interval 535.5-535.9 m and 528.2-528.4m. Frequent concretions of calcite sizing from 0.1 x 0.2 cm to 0.5 x 1.0 cm are described within the interval 527.4 -527.8m and 531.7-534.8 m. Contact with underlying layer is at the angle 0°.		527.4-534.8m. concretions of calcite						61 530.0m ~ 530.5m		0	97
		533.45		∠0°									0	97
			Dark gray-greenish gray, alternation beds of fine-grained sandstone and siltstone bedded at the angle 5° with calcite films and pyrite concretions at joints. Contact with underlying layer is at the angle 0°.		537.8-539.0m. Weakly disseminated by pyrite						62 528.0m ~ 528.5m		0	97
		540.75		∠0°									0	97
			Pale gray-greenish gray, alternation beds of fine-grained sandstone (with siliceous cement and) siltstone bedded at the angle 0°. Lamination and graded bedding structure are developed. Weak pyrite dissemination is observed at the sandstone layers. Oil saturation in the interval 544.45-545.80m and 549.50-550.35m.		540.75-552.15m. Weak pyrite dissemination in the sandstone layers. 544.45-545.80m and 549.50-550.35m. Oil saturation						63 540.0m ~ 540.5m		0	97
		552.15		∠0°									0	97
			Greenish-gray - dark gray, sandy siltstone. Structure is bedded at the angle 0-5° due to fine lamination with dark-grey sandstone. Contact with underlying layer is gradual. 556.8-557.15m gray, medium grained sandstone with weak pyrite dissemination and with Oil saturation.	∠0°	556.8-557.15m. weak pyrite dissemination and Oil saturation.						64 550.0m ~ 550.5m		0	97
		559.00	Pale gray, Coarse fine grained sandstone, with graded bedding and lamination structure, bedding structure at the angle 10°.	∠10°	559.00-560.00m. Weak pyrite dissemination						65 540.0m ~ 540.5m	∠5°	1	97
											66 548.0m ~ 548.5m		0	97
											67 545.0m ~ 545.5m		0	97
											68 558.0m ~ 558.5m	∠40°	2	97

Zhaman Formation (Gray Sandstone)

Appendix 12-9 Geological Logging of the Drill Hole "MJK-1" (9/10), Zhaman-Aibat Ore Deposit

MJK-1

AREA: ZHAMAN-AIBAT INCLINATION: -90° BEARING: — ELEVATION: 357.04m FINAL DEPTH: 650.50m

DEPTH (m)	DESCRIPTION	Angle	REMARKS
561.70	Gray, coarse-fine grained sandstone, with siliceous cement. Graded bedding structure is developed at the angle 5°. Calcite films and fine abundant pyrite impregnation filling joint are observed through the layer.	∠5°	Zhezkazgan Formation (Grey Sandstone)
568.00	Gray-pale greenish gray, fine alternation beds of sandy siltstone and fine grained sandstone, at the angle 5°-15°. Sometimes it contains sand-balls. Cristals and concretions of pyrite are observed at the interval from 564.6 to 565.0m. Contact with underlying layer is at the angle 0°.	∠5°~15°, ∠0°	
578.20	Pale gray, coarse-fine grained sandstone with siliceous-carbonaceous cement, graded bedding structure is developed. Weak pyrite dissemination is observed all through the layer. Partially including brecciated siltstone fragments at the interval from 573.4 to 574.1m and from 576.0 to 577.9m. Bedding structure is horizontal, sometimes cross-bedded at the angle 5°-15°. Joints are oriented at the angle 5°-35°. Contact with underlying layer is wavy and gradual.	∠5°~15°	
	Alternation beds of Sandstone and siltstone, horizontally bedded. 583.0-585.3m: Weak pyrite dissemination Sandstone layers: Coarse-medium-fine grained sandstone layers showing graded bedding structure with Weak oil odor, Thickness: 0.5m-1.2m. Abundant fragments of greenish gray siltstone are observed in the layer. Contact with underlying layer is wavy (load cast ?). Siltstone layers: Greenish gray, Rare carbonaceous concretions with size up to 1.0 x 1.5cm and black mud ball are observed in the layer.	∠0°	
585.30	Gray, fine grained laminated sandstone, horizontally bedded. Dark gray colored interlayers with abundant pyrite are observed through the sandstone layer. Contact with underlying layer is at the angle 10°.		
590.94	Gray-dark gray, laminated and thinly bedded sandstone including a small quantity of siltstone thin layers. Distinct graded bedding structure (bedding inclination; 0°-10°) is observed. Pyrite dissemination is observed all through the layers, strongly disseminated zones are distributed in the coarse grained sandstone layers.	∠0°, ∠0°	
597.60	Dark gray, alternating beds of fine grained sandstone(arenite) and siltstone, bedded at the angle 0°-5°. Chalcocite concentrated thin layers and weak pyrite dissemination (including a small amount of galena-chalcopyrite-bornite) are observed at the sandstone layers.	∠0°~10°	Weakly Mineralized Zone
600.12	Light gray-brown, medium grained massive sandstone, containing a small amount of conglomerate and siltstone thin layers, bedded at the angle 3°-7°. Dissemination by chalcocite (>>galena, bornite, chalcopyrite>pyrite) are observed within the interval 599.0-605.78m.	∠3°~7°	
608.27	Brownish light gray-greenish light gray, intraformational conglomerate (RAIMUNDO Conglomerate), consisting of angular fragments of white or pink-colored limestone and siltstone (sizing from 5 x 5mm to 15 x 30mm) and cement of green colored (caused by weak chloritization) muddy sandstone. At the bottom of the layer, cement is represented by red sandstone. No mineralization observed.	∠5°~7°	Cu-Mineralized
609.30 610.75	Gray (partially brown), fine-medium grained sandstone(arenite) with siliceous-carbonaceous cement with horizontal graded bedding structure. Contact with underlying layer is wavy. Very weak pyrite dissemination is observed.	∠0°	Weakly Mineralized
614.35	Reddish brown, siltstone with indistinct bedded structure. Calcite concretions with size 0.3 x 0.6cm and no mineralization observed.		Teskuduk Formation
621.40	Reddish light brown, laminated fine-medium grained sandstone, bedded at the angle 5°-10°. Reddish brown colored shale layer is observed within the interval 617.20-618.30m. Contact with underlying layer is wavy.	∠5°~10°	
	Reddish brown, horizontally bedded siltstone, containing calcite concretions sizing from 0.3 x 0.5cm to 0.5 x 2.0cm. Brown colored laminated sandstone layer is observed within the interval 624.65-625.90m and 628.00-630.00m.	∠0°	

Scale (m): 570, 580, 590, 600, 610, 620, 630

MINERALIZATION

(Columns: SULFIDE, SILICA, CLAY, CARBONATE, SULFATE)

560.00-561.70m: pyrite dissemination (medium) and calcite films (weak)

564.6-565.0m: Strongly disseminated by pyrite
565.0-568.0m: Weakly disseminated by pyrite

568.00-578.20m: Weak pyrite dissemination

583.0-585.3m: Weak pyrite dissemination
Sandstone layers: Weak oil odor

585.30-590.94m: Thin layers with pyrite concentration

590.94-597.60m: Pyrite dissemination
- 590.94-592.72m: strong
- 592.72-593.95m: weak
- 594.35-594.64m: strong
- 594.64-595.80m: weak
- 595.80-597.60m: strong

599.00-600.12m: Chalcocite concentration layers and weak pyrite dissemination

600.12-605.78m: Dissemination by chalcocite (>>galena, bornite, chalcopyrite >pyrite)
- 600.12-605.78m: strong
- 605.78-607.98m: very weak

609.30-610.75m: Very weak pyrite dissemination

614.35-621.40m: Very weak pyrite dissemination

Appendix 15-1 Microscopic Observation of Polished Sections from the Drill Hole "MJK-1", Zhaman-Aibat Ore Deposit

Sample No.	Drill No.	From (m)	To (m)	Location	Observation	Cc	Bn	Cv	El	Dz	Gr	Go
95-PS-01	MJK-1	599.82	600.02	Eastern Orebody	Chalcocite-like minerals mainly chalcocite and small amounts of digenite and djurleite(60%), bornite (38%), electrum (1%), goethite(1%), and gangue minerals are constituent minerals. Chalcocite-like minerals and bornite occur as interstice-filling product among sedimentary particles and as veinlets in clay-rich parts of the rocks. Ag-rich electrum (max 0.1mm in size) occurs in veinlets of less than 2mm in width, which consist of chalcocite-like minerals (mainly chalcocite) and less bornite, in dark bluish green clay.	◎	○		+			+
95-PS-02	MJK-1	600.40	600.77	Eastern Orebody	Chalcocite-like minerals mainly chalcocite (95%), goethite (4%), covellite (1%) and gangue minerals are constituent minerals. Chalcocite-like minerals are interstitial among sedimentary particles. Aggregates of goethite grains as secondary products probably after pyrite within some of sedimentary particles are also observed.	◎		+				△
95-PS-03	MJK-1	600.77	601.75	Eastern Orebody	Chalcocite-like minerals (mainly chalcocite, less digenite and rare djurleite)(98%), goethite (2%) and gangue minerals are constituent minerals. Chalcocite-like minerals occur interstice-filling products among sedimentary particles, and also within some of the particles. Goethite occurs as secondary products after pyrite.	◎						△
95-PS-04	MJK-1	601.75	602.17	Eastern Orebody	This constitutes chalcocite-like minerals (chalcocite >> digenite > djurleite) (80%), bornite (19%), gersdorffite-cobaltite series mineral (1%) and gangue minerals. Chalcocite-like minerals occur as aggregates of small grains and dots and occasionally as patches up to 3mm x 5mm in size. Bornite occurs as small inclusions in chalcocite-like minerals and as anhedral grains with chalcocite-like minerals up to 40 micro-m in size. In such a case, these minerals tend to arrange linearly in the rock . Gersdorffite-cobaltite series mineral occurs as small euhedral crystals in chalcocite-like minerals generally with bornite inclusion, and might be misunderstood as skutterudite by Russian researcher.	◎	○				+	
95-PS-05	MJK-1	602.17	602.68	Eastern Orebody	Chalcocite-like minerals (mainly chalcocite and less digenite) (97%), bornite (1%), covellite (1%) and gangue minerals are constituent minerals. Chalcocite-like minerals occur interstitially among sedimentary particles. Bornite rarely occurs as small inclusions in chalcocite-like minerals. In such a case, bornite is surrounded by secondary djurleite which is an alteration product after chalcocite. Covellite and goethite are also secondary products after chalcocite-like minerals and probably pyrite, respectively.	◎	+	+				+
95-PS-06	MJK-1	602.68	603.10	Eastern Orebody	This polished section consist of chalcocite-like minerals (mainly chalcocite) (98%), bornite (1%), goethite (1%), and gangue minerals. Interstitial chalcocite-like minerals among sedimentary particles are predominant. Bornite occurs as small inclusion in chalcocite-like minerals. Goethite occurs as secondary products after pyrite in some of sedimentary particles.	◎	+					+
95-PS-07	MJK-1	605.00	605.20	Eastern Orebody	This is also composed of chalcocite-like minerals (mainly chalcocite) (99%), goethite (1%) and gangue minerals. Chalcocite-like minerals occur as interstice-filling products among sedimentary particles. Goethite occurs in some of sedimentary particles as secondary products after pyrite.	◎						+
95-PS-08	MJK-1	605.20	605.34	Eastern Orebody	This polished section consists of chalcocite-like minerals (mainly chalcocite and less digenite) (99%), goethite (1%) and gangue minerals. Chalcocite-like minerals occur as interstice-filling products among sedimentary particles. The sulphide minerals are generally more concentrated in sandy parts than silty parts.	◎						+

Cc: Chalcocite like minerals, Bn: Bornite, Cv: Covellite, El: Electrum, Dz: Zhezkazganite, Gr: Gersdorffite-cobaltite series minerals, Go: Goethite

◎: more tan 50%, ○: 30% - 50%, △: 10% - 30%, +: less than 10%

Appendix 1 5 - 2 Microscopic Observation of Polished Sections from the Drill Hole "MJK-1", Zhaman-Aibat Ore Deposit (continued)

Sample No.	Drill No.	From (m)	To (m)	Location	Observation	Cc	Bn	Cv	El	Dz	Gr	Go
95-PS-09	MJK-1	605.47	605.61	Eastern Orebody	Chalcocite-like minerals (mainly chalcocite) (97%), electrum (2%), goethite (1%) and gangue minerals are constituent minerals. Chalcocite-like minerals interstitially occur among sedimentary particles. Ag-rich electrum occurs as small inclusions up to 50 micro-m in size in open spaces in chalcocite-like minerals and in direct contact with chalcocite-like minerals. Goethite occurs as secondary products after pyrite.	◎			△			+
95-PS-10	MJK-1	The South Mine of the Zhezkazgan Mine			Sulphide minerals is predominant. It is composed of chalcocite-like minerals (mainly chalcocite) (60%), bornite (39%), electrum (1%) and gangue minerals. All of these ore minerals occur as interstice-filling products among sedimentary particles with quartz and other gangue minerals which occur as euhedral crystals. Chalcocite-like minerals and bornite coexist with each other. Ag-rich electrum is included within both chalcocite-like minerals and bornite, and the former case is rather common. Rarely "dzhezkazganite"-like minerals (?) occurs in chalcocite-like minerals, but it is difficult to identify this phase because of its tiny size.	◎	○		+	+?		

Cc: Chalcocite like minerals, Bn: Bornite, Cv: Covellite, El: Electrum, Dz: Zhezkazganite, Gr: Gersdorffite-cobaltite series minerals, Go: Goethite
◎: more tan 50%, ○: 30% - 50%, △: 10% - 30%, +: less than 10%

Appendix 16 Microscopic Observation of Thin Sections from the Drill Hole "MJK-1", Zhaman-Aibat Ore Deposit

Sample No.	DDH No.	Depth (m)	Formaton	Rock Name	Description	Identified Minerals
95-TS-01	MJK-1	203.5	Zhiderisai Formation	Laminated siltstone (red aleurolite)	average diameter : 0.02 - 0.05mm matrix : carbonitization (weak)	quartz, plagioclase, K-feldspar, sericite, chlorite, smectite, goethite(?)
95-TS-02	MJK-1	329.4	Zhiderisai Formation	Calcareous sandstone (red sandstone)	average diameter : 0.15mm matrix : carbonitization	quartz, carbonate minerals (mostly calcite), plogioclase, K-feldspar, opeque minerals, chlorite
95-TS-03	MJK-1	458.9	Zhezkazgan Formation	Thin laminated siltstone	average diameter : 0.02 - 0.0mm matrix : carbonitization	quartz, plagioclase, K-feldspar, opeque-minerals, carbonate minerals (mostly calcite), smectite
95-TS-04	MJK-1	539.9	Zhezkazgan Formation	Thin laminated siltstone	average diameter : 0.15 - 0.05mm matrix : carbonitization	quartz, plagioclase, K-feldspar, opeque minerals, carbonate minerals (mainly calcite), chlorite
95-TS-05	MJK-1	586.2	Zhezkazgan Formation	Calcareous fine-grained laminated sandstone	average diameter : 0.15mm matrix : carbonitization	quartz, plagioclase, K-feldspar, opeque minerals, carbonate minerals (mainly calcite),
95-TS-06	MJK-1	601.5	Zhezkazgan Formation	Thin bedded (or laminated) sandstone	average diameter : 0.4mm matrix : carbonitization, copper minerals	quartz, plagioclase, K-feldspar, opeque minerals, carbonate minerals (mainly calcite), tourmaline
95-TS-07	MJK-1	644.2	Taskuduk Formation	Calcareous sandstone	average diameter : 0.2mm matrix : carbonitization	quartz, plagioclase, K-feldspar, opeque minerals, carbonate minerals (mainly calcite), sericite, chlorite, smectite

Appendix 26-1 Microscopic Observation of Polished Sections from the Drill Hole "MJK-2", Zhaman-Aibat Ore Deposit

Sample No.	Drill No.	Depth (m)	Location	Observation	Cc	Bn	Cv	St	El	Py	Cp	Gn	Sp	Go
96-PS-01	MJK-2	608.10	Central Orebody	This polished section consist of galena (40%), pyrite (30%), chalcopyrite (20%), goethite (10%), and gangue minerals. Aggregates of anhedral grains of galena, anhedral grains of chalcopyrite, and euhedral to subhedral grains of pyrite (some of them are brecciated), up to 0.8mm in size, fill among sedimentary particles (sands). Goethite looks like a secondary product after pyrite or marcasite.						○	△	○		△
96-PS-02	MJK-2	608.35	Central Orebody	The constituent minerals are galena (40%), pyrite (30%), chalcopyrite (20%), bornite (5%), goethite (5%), and gangue minerals. Like 96-PS-01, these opaque minerals except goethite occure as aggregates up to 2mm in size, showing interstice-filling among sedimentary particles (sands)		+				○	△	○		+
96-PS-03	MJK-2	608.88	Central Orebody	The opaque constituents of this polished section are galena (50%), pyrite (30%), bornite (10%), goethite (10%) and gangue minerals. Chalcopyrite was not found. Aggregates of anhedral grains of galena, subhedral - euhedrl grains of pyrite, and anhedral bornite, up to 1.2mm in size, occur interstitially among sedimentary particles. This sandstone has layering almost horizontally, but there is no regularity on arrangement of the opaque minerals.		△				○		◎		
96-PS-04	MJK-2	609.32	Central Orebody	This polished section is composed of bornite (30%), chalcocite-like minerals (30%, in this case, chalcocite is predominant, but a small amount of digenite is also found), chalcopyrite (10%), covellite (5%), pyrite (5%), stromeyerite (5%), galena (5%), organic matters (5%) and gangue minerals. These opaque minerals except goethite and organic matters occure as aggregates of irregulaar shape, up to 2.5mm in size, interstitially among sedimentary particles (sands). Also, bornite and chalcocite-like minerals sometimes show micrographic texture.	○	○	+	+		+	△	+		
96-PS-05	MJK-2	609.60	Central Orebody	It consists of galena (50%), chalcocite-like minerals (20%, chalcocite is predominant), bornite (15%), covellite (5%), pyrite (5%), organic matters (5%) and gangue minerals. These opaque minerals except organic matters occure as aggregates, up to 2mm in size, interstitially among sedimentary particles (sands). Galena occures as relatively coarse grains as a member of the aggregates above mentioned, and and anhedral grains of galena with inclusions of fine grained gangue minerals. The latter aggregates do not include other sulfide minerals in general, or are contained in the former aggregates as breccias. It suggests that galena has at least two stages of formation.	△	△	+			+		◎		
96-PS-06	MJK-2	610.20	Central Orebody	This polished section is composed of chalcocite-like minerals (40%, chalcocite is more dominant than digenite), bornite (40%), galena (10%), organic matters (5%) and gangue minerals. Anhedral grains of chalcocite-like minerals, bornite and galena occure as aggregates of interstice-filling products, up to 3mm in size, among sedimentary particles (sands). One undetermined mineral is observed in such aggregates as subhedral columnar grains up to 0.15mm in size. It is gray in color, and clearly anisotropic.	○	○						△		
96-PS-07	MJK-2	610.70	Central Orebody	The opaque minerals od this polished section, which is predominant in sulfide minerals, are chalcocite-like minerals (50%, digenite and chalcocite are nearly same amount), bornite (45%), and Ag-rich electrum (5%). Chalcocite-like minerals and bornite occur as aggregates, up to 3mm in size, interstitially among particles (sands), and occasionally show micrographic texture. Anhedral grains of Ag-rich electrum, up to 02mm x 0.1mm in size, occers in some of the sedimentary particles with probably clay minerals, not quartz sands.	◎	○			+					+

Cc: Chalcocite like minerals, Bn: Bornite, Cv: Covellite, St: Stromeyerite, El: Electrum, Py: Pyrite, Cp: Chalcopyrite, Gn: Galena, Sp: Sphalerite, Go: Goethite
◎: more tan 50%, ○: 30% - 50%, △: 10% - 30%, +: less than 10%

Appendix 26-2 Microscopic Observation of Polished Sections from the Drill Hole "MJK-2", Zhaman-Aibat Ore Deposit (continued)

Sample No.	Drill No.	Depth (m)	Location	Observation	Cc	Bn	Cv	St	El	Py	Cp	Gn	Sp	Go
96-PS-08	MJK-2	611.80	Central Orebody	This polished section consists of chalcocite-like minerals (60%, chalcocite is more dominant than digenite), bornite (40%) and gangue minerals. These opaque minerals occur as aggregates, up to 1mm in size, interstitially among sedimentary particles (sands), and occasionally show micrographic texture.	◎	○								
96-PS-09	MJK-2	612.30	Central Orebody	This polished section is composed of chalcocite-like minerals (60%, chalcocite and digenite are nearly same amount), bornite (35%), organic matters (5%) and gangue minerals. These opaque minerals are sometimes concentrated in some layers or veinlets in the host sandstone, and occur as anhedral grains in interstitial aggregates among sedimentary particles (sands). At least two kinds of gamgue minerals are coexisted with these opaque minerals at the stage of ore-formation.	◎	○								
96-PS-10	MJK-2	613.50	Central Orebody	It consitsts of chalcocite-like minerals (50%, digenite looks more dominant than chalcocite), bornite (45%), goethite (5%) and gangue minerals. Anhedral grains of chalcocite-like minerals and bornite occur as aggregates, up to 1,5mm in size, interstitially among sedimentary particles, and sometimes show micrographic texture.	◎	○								
96-PS-11	MJK-2	615.50	Central Orebody	This polished section is composed of chalcocite-like minerals (60%, chalcocite and digenite are nearly same amount), bornite (40%),and gangue minerals. Chalcocite-like minerals and bornite occur as aggregates, up to 2mm in size, interstitially among sedimentary particles, and sometimes show micrographic texture.	◎	○								
96-PS-12	MJK-2	617.70	Central Orebody	This polished section consists of chalcocite-like minerals (60%, chalcocite and digenite are nearly same amount), bornite (40%), and gangue minerals. These opaque minerals are also interstice-filling products, up to 1mm in size, among sedimentary particles (sands).	◎	○								
96-PS-13	MJK-2	630.05	Central Orebody	This polished section is composed of chalcocite-like minerals (90%, chalcocite is more dominant than digenite), goethite (5%), organic matters (5%) and gangue minerals. Chalcocite-like minerals occur as irregular-shaped aggregates, up to 2mm in size, interstitially among sedimentary particles (sands). They occasionally arrange like veinlets.	◎									
96-PS-14	MJK-2	635.65	Central Orebody	This polished section is composed of chalcocite-like minerals (95%, chalcocite is more dominant than digenite), pyrite (5%), and gangue minerals. Anhedral grains of chalcocite-like minerals, up to 0.2mm in size, scarcely occur among sedimentary particles (sands). Pyrite is included in some of the sedimentary particles, and seems not to be related to ore-mineralization.	◎					+				
96-PS-15	MJK-2	688.10	Central Orebody	This polished section consists of pyrite (30%), chalcopyrite (30%), galena (30%),sphalerite (10%) and gangue minerals. The amount of sulfide minerals is not much. Aggregates of anhedral grains of chalcopyrite, galena and sphalerite occur as interstice-filling products, up to 1mm in size, among particles.						○	○	○	△
