#### APPENDIX 3 DATA PROCESSING FOR PERSON TRIP MASTER DATABASE

In order to analyze the present situation of transportation systems and travel behavior of the citizen of Managua, the Study Team conducted a series of surveys. The most large-scale survey is the person trip survey, having a sample size of 9,000 households. The purpose of the Person Trip Survey is to know quantitatively the characteristics of personal trip behavior. Present 'Origin and Destination' matrices (hereinafter called OD matrix) can be estimated based on the information obtained by this survey through data processing. In this section, the data processing methodology, i.e. how to create database and how to estimate OD matrices, is discussed.

#### 1. Outline

The data processing for creation of Person Trip master database can be roughly divided into four major steps: data correction, expansion of Person Trip Survey data, processing of cordonline survey data and screenline adjustment as shown in Figure 1.1.

(a) Data check and correction

After the field survey being completed, the raw data of the Person Trip Survey was coded and inputted into database by a number of coders. Thus, the database usually includes wrong information due to various types of mistakes. Therefore, the database must be checked thoroughly through the following three steps: order check, validity check and logical check.

(b) Expansion of Person Trip Survey Data

A Person Trip Survey is a sample survey and needs expansion in order to represent the characteristics of the whole population. The expansion is, in general, closely related to the methodology of sampling. The target households were selected by the manner called "Area Sampling" in this project. (c) Processing of Cordonline Survey data

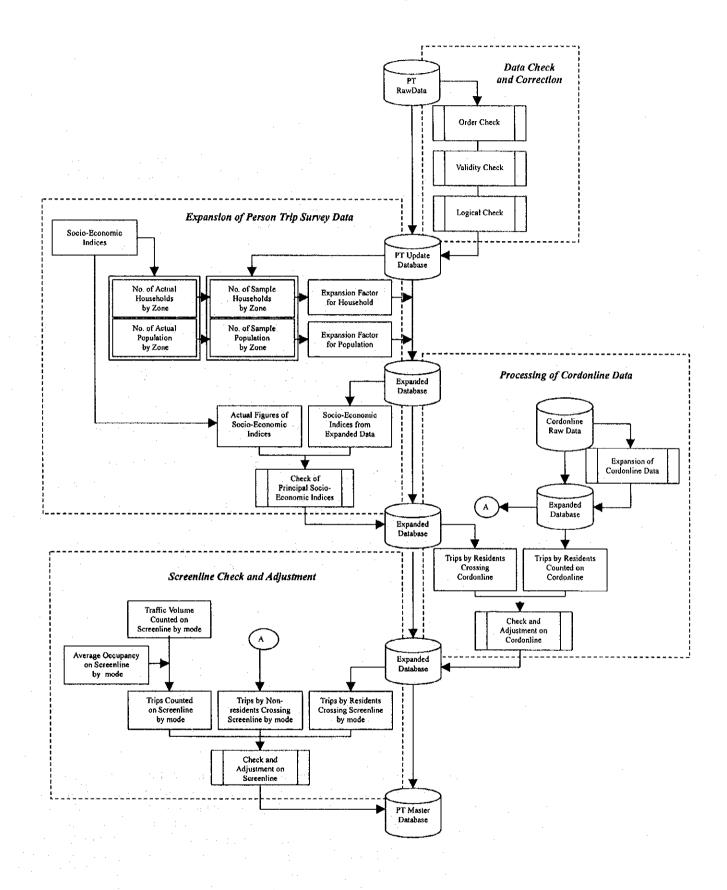

The purpose of processing of Cordonline Survey data is two-fold; creation of OD matrices of non-residents and adjustment of expansion factors for the trips of residents crossing the cordonline.

(d) Screenline check and adjustment

The traffic volume by vehicle type, crossing the screenline is estimated from the expanded person trip survey results, and then compared with the actually counted traffic volume on the screenline. The initially calculated expansion factors are then adjusted based on this comparison. Although the details are explained hereafter, the traffic by non- residents and average occupancy by vehicle type are the major factors to be taken into account.

A detailed flow chart of the master database creation is shown in Figure 1.2.

Figure 1.2 Flow Chart for Creation of Person Trip Master Database

### 2. Data check and Correction

The Person Trip data were examined through the following methods:

- (a) Order check
- (b) Validity check
- (c) Logical Check

### (1) Order Check

The database has three types of record, i.e household information, personal information and trip information. These records should be inputted in the following order shown in Figure 2.1.

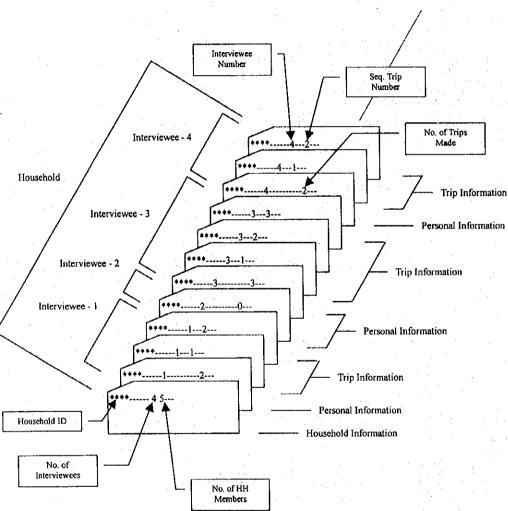

Figure 2.1 Data Order in Database

The first record of a data set for one household is for household information, on which the number of interviewees in the household is recorded, followed by personal information. For this personal information, the same number of records as the number of interviewees should be inputted. If an interviewee made trips, records for trip information should be inputted according to the number of trips he or she made. If he or she did not make a trip, it is not necessary to input a record for trip information.

### (2) Validity check

Validity of every numerical and categorized data should be checked according to its possible range. Some of the data had been automatically checked by data-input software when it was inputted.

### (3) Logical Check

The last step is to check the consistency among the three sorts of information. Inconsistency to be checked can be divided into the following categories:

(a) Personal attributes:

Inconsistencies among sex, age, activity condition, occupation, industry and working/school place zone are checked.

(b) Between personal attribute and trip information:

Inconsistency between occupation and trip purpose is checked.

(c) Travel Time

Inconsistency of start/arrival time between trips. Inconsistency of start time and trip purpose. Inconsistency of travel time and travel mode.

### 3. Expansion of Person Trip Survey Data

The Person Trip Survey was undertaken to interview all the members that belong to a family selected by random sampling in each traffic zone. Moreover, there may be a member who refused to be interviewed. Therefore, the results of the survey should be expanded to provide the complete information reflecting the whole activities of all the population of the Study Area.

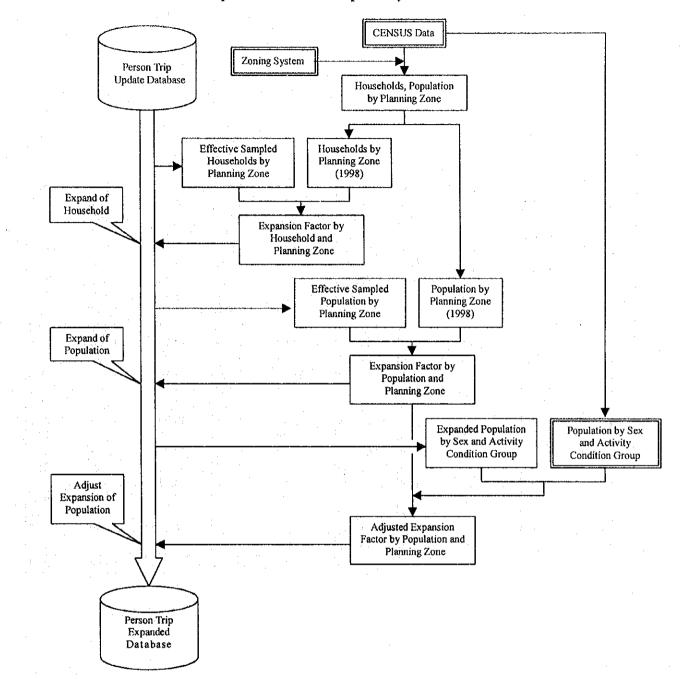

When sampled data is expanded, the following points should be examined.

- (a) Manner of random sampling.
- (b) Significant difference of distribution between sampled data and known population by attribute.
- (c) Regional differences of characteristics

In the process of expansion, the bias of the sampled data can be eliminated so that no statistically significant difference exists, if the expansion factor is properly set according to the distribution of known attributes. In the Person Trip Survey, households were selected by random sampling. If there is a bias in the household size and in some attribute structure of households, the expanded result will show a deviation from the actual attribute structure. Taking this into account, the expansion was done independently based on the number of households and on the population by sex and activity condition as follows:

- (a) Calculate population and number of households by zone.
- (b) Compare the total number of households and the effective number of interviewed households by planning zone to obtain the expansion factor for households.
- (c) Compare the total population and the effective number of interviewed persons by planning zone to obtain the expansion factor for population.
- (d) Compare the number of population and the expanded number of population by sex and activity condition group to obtain the adjustment figures for expansion factor by sex and activity condition group.

### 4. Processing of Cordonline Survey Data

In the Cordonline Survey, traffic volumes were counted by type of vehicle and sampled drivers were simultaneously interviewed to obtain detailed travel information, such as origin and destination of trips, and purpose. The OD information collected by cordonline survey station was expanded as against the counted traffic volume, and were compiled into OD matrices by survey station. In order to obtain OD matrices for both residents and non-residents separately, these station-wise OD matrices should be consolidated. The OD pairs crossing the cordonline only once were summed. The OD pairs crossing the cordonline twice were summed and their averages were taken for the OD. The matrix for residents was compared with the OD matrix calculated from the Person Trip Survey in order to adjust the number of person trips traveled by residents crossing the cordonline. The matrix for non-residents was then added to the OD matrix.

### 5. Screenline Checking and Adjustment

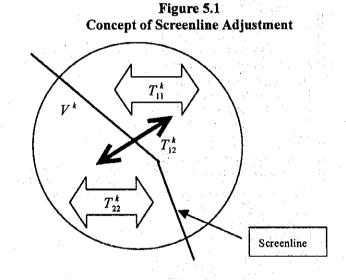

The OD matrix obtained from the Person Trip Survey can be checked for accuracy by comparing it with the results of the screenline traffic count survey. If the traffic volume calculated from the OD matrix are significantly different from the present traffic flow, the OD matrix should be adjusted to represent the existing situation.

During the process of screenline adjustment, the following issues had to be discussed:

- (a) The Person Trip Survey deals with person trips while the screenline survey counts vehicular traffic.
- (b) The Person Trip Survey deals with the traffic of residents while the screenline count includes the traffic made by non-residents.

#### (1) Concept of Screenline Adjustment

The screenline adjustment aims to adjust the person trip data by multiplying the ratio between the screenline traffic and the person trip data  $(V_k / T_{12}^k)$  with all the person trip data  $(T_{11}^k, T_{12}^k, T_{22}^k)$ , as shown in Figure 5.1.

 $V^k$ :Screenline traffic of vehicle type k $T_{12}^k$ :Person trip traffic crossing the screenline of vehicle type k $T_{11}^k, T_{22}^k$ :Person trip traffic not crossing the screenline of vehicle type k

### (2) Average Occupancy by Vehicle Type

In order to compare the counted vehicular traffic volume and the estimated number of person trips, the average occupancy or average number of persons per vehicle must be determined by vehicle type. The occupancy was surveyed by vehicle type on the screenline at the same time as the traffic counts. The result of occupancy survey is shown in Table 5.1.

AV	erage Occupancy	by vehicle 1	ype
		No. of	Average
Mode		Surveyed	Occupancy
Number	Vehicle Type	Samples	Ratio
2	Car	15,418	1.963
- 3 -	Light Truck	2,723	1.706
4	Large Truck	2,448	1.667
5	Trailer	1,720	1.592
6	Taxi	16,153	1.830
7	Passenger Truck	-	-
8	Microbus	4,644	6,167
9	Bus	4,560	29,525
10	Motorcycle	8,035	1.286
11	Bicycle	2,484	1.004

### (3) Screenline Traffic by Non-Residents

The traffic volume counted on the screenline includes that of non-residents. In order to exclude the non-resident traffic from the screenline traffic, the OD matrices of non-residents must be identified. These could be obtained from the cordonline survey, and its cross-screenline traffic was subtracted from the screenline traffic.

### (4) Adjustment Value from Screenline Checking

Table 5.2 shows the result of traffic count survey on the screenline by type of vehicles and survey station. Table 5.3 shows the result of the screenline adjustment done according to the methodology explained previously. Consequently, the obtained adjustment value by type of vehicles is applied to adjust the expansion factor for trip information.

### APPENDIX 5 INTERSECTION ANALYSIS

### 1) Evaluation of Existing Signalized Intersections

- Out of 26 signalized intersections surveyed of traffic volume and signal phases, 24 were analyzed (No. 16 Montoya and No. 34 Gonzalez Theatre in Dupla Norte were excluded due to the wide-spread geometrical configurations) by HCS (Highway Capacity Software).
- HCS was prepared based on the 1994 HCM (Highway Capacity Manual) by TRB (Transportation Research Board) and FHWA (Federal Highway Administration) of USA. This software first assumes unadjusted service volumes in terms of mixed vehicle per hour of green for Standard Conditions (5% left-turning vehicles, 10% right-turning vehicles and no local transit bus). Then adjustments are made on the cycle time and green time based on actual directional flows at the intersection. The level of service before and after the adjustment is the output of this software.
- The following table presents the result of HCS application to the 24 intersections in Managua. The following can be pointed out:
  - 1. Most of existing signalized intersections are already saturated or nearly saturated under the current phasing.
  - 2. After some adjustment, however, the level of service will be greatly improved for most intersections.
  - 3. There are four (4) intersections which need geometrical improvement.
  - 4. There are 32 other signalized intersections in Managua not surveyed in this study. It is likely that these intersections also require adjustment of phasing.

Note: 1) Intersection No. Corresponds to the intersection traffic count survey conducted in February 1998. 2) Level of Service: LEVEL OF SERVICE A: This is a condition of free flow, accompanied by low volumes and high speeds. Traffic density will be low, with uninterrupted flow speeds controlled by driver desires, speed limits and physical roadway conditions. There is little or no restrictions in maneuverability due to the presence of other vehicles, and drivers can maintain their desired speeds with little or no delay. LEVEL OF SERVICE B: This occurs in the zone of stable flow, with operating speeds beginning to be restricted somewhat by traffic conditions. Drivers still have reasonable freedom to select their speed and lane of operation. Reductions in speed are not unreasonable, with a low probability of traffic flow being restricted. The lower limit (lower speed, highest volume) of this level of service has been used in the design of tural nighways.

LEVEL OF SERVICE C: This is still in the zone of stable flow, but speeds and maneuverability are more closely controlled by the higher volumes. Most of the drivers are restricted in their freedom to select their own speed, change lanes, or pass. A relatively satisfactory operating speed with service volumes suitable for urban design practice.

LEVEL OF SERVICE D: This level of service approaches unstable flow, with tolerable operating speeds being maintained, though considerably affected by changes in operating conditions. Fluctuations in volume and temporary restrictions to flow may cause substantial drops in operating speeds. Drivers have little freedom to maneuver, and comfort and convenience are low. These conditions can be tolerated, however, for short periods of time. LEVEL OF SERVICE E: This cannot be described by speed alone, but represents operations at lower operating speeds, with volumes at or near the capacity of the highway. Flow is unstable and there may be stoppages of momentary duration. This level of service is associated with operation of facility at capacity flows.

LEVEL OF SERVICE F: This describes a force-flow operation at low speeds, where volumes are below capacity. In the extreme, both speeds and volume can drop to zero. These conditions usually result from a restriction downstream. The section under study will be serving as a storage area during parts or all of the peak hour. Speeds are reduced substantially and stoppages may occur for short or long periods of time because of the downstream congestion.

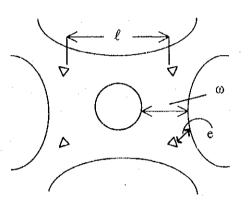

### 2) Capacity calculation of Existing Roundabouts

• At present, there are five (5) roundabouts in Managua. Based on the geometric design, their capacity has been calculated as shown below:

	Din	nension (	m)	Capacity <sup>3)</sup>
Name	• e <sup>1)</sup>	ω <sup>1)</sup>	$\ell^{1}$	(veh./hr)
Metrocentro	9.00	14.00	57.70	2,960
Plaza España	13.25	14.00	48.25	3,380
Santo Domingo	15.50	16.22	54.75	3,920
Centro America <sup>2)</sup>	12.50	14.00	48.00	3,280
Villa Progreso	16.00	18.00	71.25	4,340

#### Capacity of Existing Roundabouts

Note 1)

- 2) This roundabout is not conventional with flares. The calculated capacity may not be accurate.
- 3) Formulae:

Capacity Q =  $\frac{160}{1 + \omega / \ell}$ (vehicle inflow: veh./hour)

TRRL (Transport and Road Research Laboratory), UK

Considering that all the legs of these roundabouts are 4-lane roads, the calculated capacity of 3,000 - 4,300 vehicles/hour seems to be smaller than that of signalized intersection (around 6,000 - 8,000 vehicles/hour).

### 3) Comparison of Roundabout and Signalized Intersection

- The following table compares the performance of signalized intersection and roundabout for the same traffic flows. The intersection is imaginary but typical in Managua. The analysis was done by SIDRA (Signalized and Unsignalized Intersection Design and Research Aid).
- The following can be pointed out:
  - 1. The total capacity is larger in signalized intersection than in roundabout. Although the degree of saturation does not differ much, signalized intersection has more room for adjustment of signal phases.
  - 2. Overall average delay time is similar. But in the case of roundabout, delay may be extremely large in some specific directions.

### Comparison of Signalized Intersection and Roundabout

	1,000 m

"Key Route" network plan

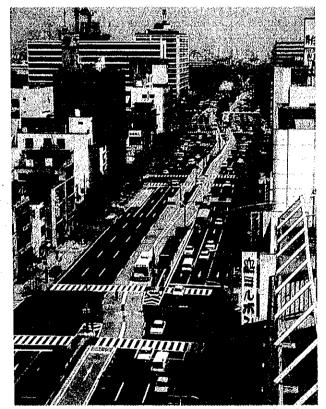

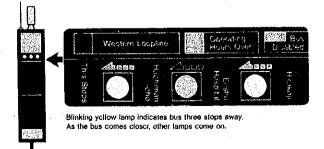

Concept and display of approaching bus information system

Shindekimachi line, with bus lanes in the center of roadway

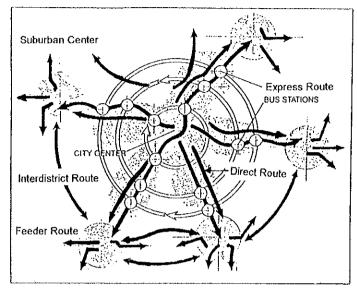

### Integrated Transportation Network - Curitiba (Brazil)

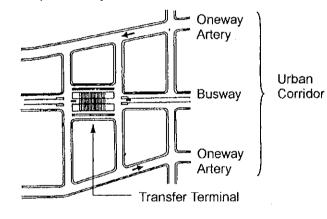

01 0	
City Population	1.6 million
Urban Public	Integrated bus service provided
Transportation	by 10 independent companies
Services	contracted by city authority.
New Bus System	Busway and bus lane
Length of New Bus System	56 km (city total 1,217 km)
Fare	Flat set by city, double for
	executive midibus service and
	lower for city center and
	neighborhood routes
Start Year	1974
Purpose of New	Reduce travel time and
Bus System	stopping time at stops
	Provide comfort for
	passengers
	Provide scheduled operation
System Features	<ul> <li>Busway and bus lane</li> </ul>
	Bus priority signals at
	junctions by bus actuation or
	area traffic control
	High capacity bus fleets (bi-
	articulated buses :270 pax)
	Tube stations (every 400 m)

#### APPENDIX 8 VEHICLE OPERATING COST (VOC)

Unit costs of vehicle operation are estimated in order to basic information to estimate savings in vehicle operating cost which is a main source of economic benefit of a transport project. These unit costs are estimated by type of vehicle (passenger car, microbus, bus, small truck and medium-size truck). VOC is composed of the following cost items:

- a. Fuel cost
- b. Oil cost
- c. Tire cost
- d. Maintenance cost
- e. Depreciation cost
- f. Capital opportunity cost (interest)
- g. Crew and overhead cost

In Nicaragua, the Ministry of Transport and Infrastructure (MTI) has been periodically updating VOC data as an input of the HDM Model developed by IBRD. Most input data and assumptions of the analysis in this appendix followed those of MTI. The HDM model is applied, however, to inter-municipal or inter-regional highways and then a key factor affecting VOCs is road surface conditions in terms of roughness. On the other hand, VOCs analyzed here will be used to evaluate Master Plan projects in the urban area of Managua City, where roads are mostly paved and then, the key factor is not roughness but operating speed. Then, unit VOC cost of each item is prepared by different operating speed.

#### 1. General Characteristics of Representative Vehicles

To estimate VOCs by type of vehicles, representative makes and models which are popular in Managua City are selected for each vehicle type. Their market prices are averaged to a financial price and by deducting taxes from the financial price, economic prices of each models are estimated. Table 1 shows the vehicle prices and other operational assumptions. Annual operating distance follows the MTI's estimates but average operating speed is modified based on the survey results of this Master Plan Study.

#### 2. Fuel Cost

Nicaragua does not produce but imports and refines crude oil. According to the MTI's data, the cost composition of petro-products is as shown in Table 2. Retail price of regular gasoline is US\$1.77 per gallon of which about 45% is various taxes and then economic price is US\$0.99 per gallon. In the same way, financial and economic prices of super gasoline are US\$1.89 and US\$1.10 per gallon, respectively and US\$1.40 and US\$0.85 for diesel oil.

Table 3 shows composition of fuel consumption by type of vehicles, which was estimated based on vehicle statistics of Natioanl Transport Safety Department (Dirección de Segridad de Transito Nacional) and interviewing survey to major gas station in Managua. Making averages of fuel prices weighted by these consumption ratios, economic fuel costs of passenger car and microbus are estimated at US\$0.26/liter, bus at US\$0.23, small truck at US\$0.24 and medium size truck at US\$0.23.

Fuel consumption rate of a vehicle varies by its operating speed. The most economical speed is 45 to 50 km / hour for passenger car, and 50 to 60 km/hour for medium and large vehicles. Based on various data mainly developed by a series of IBRD Studies concerning the fuel consumption rate by operating speed, fuel costs per kilometer are tabulated by type of vehicle, as shown in Table 4.

#### 3. Oil Cost

Retail price of lubricant oil is US\$1.5/liter and after deducting tax, economic cost is US\$1.2/liter. The relations between oil consumption and operating speed are as shown in Table 5. From this information, economic oil cost is estimated by operating speed.

#### 4. Tyre Cost

Table 6 presents market price and economic price of tyres by type of vehicle. Under the condition of average speed of 35 mile/hour (56 km/hour) on paved roads, average tire life assumes 45,000 km for passenger car and 50,000 km for heavy vehicle. Thus, tire consumption rates per 1,000 km are 8.9% and 12.0%, respectively. On the other hand, it is empirically known that this consumption rate becomes higher as average operating speed rises. An IBRD report ("Quantification of road user savings", IBRD Occasional Paper No.2, 1966) shows the relationship between tyre wear and speed as in Table 7. Based on this information, economic tire cost per kilometer is obtained as shown in the same table.

Although some vehicles use re-treaded tyres, they are neglected by the reasons that their market share is not significant and that the life of re-treaded tire is shorter than brand new tire even if its prices is lower, so that there is no big difference in economic price per kilometer between the two.

#### 5. Maintenance Cost

Calculating annual maintenance cost based on MTI's VOC data, the rate of annual maintenance cost to the vehicle price (excluding tyres cost) is estimated to be 4% for passenger car, and small truck and 8% for other commercial vehicles with longer operating distance. By assuming annual operating distance, maintenance cost per kilometer are calculated as shown in Table 8.

According to the said IBRD report referred to in the tyre cost estimation, the relationship between maintenance cost and operating speed shows that maintenance cost becomes lowest at around 50 km/hour of speed. Using these conversion rates, maintenance cost obtained at different speed (Table 9).

#### 6. **Depreciation Cost**

Depreciable amount is defined as the vehicle cost (without tyre cost) less salvage cost after usage during vehicle life. In Nicaragua, where market of secondhand vehicles and spare parts is fairly developed, salvage value rate can be assumed at rather high rate, namely, 25% for passenger car, 20% for small truck and 15% for others (Table 10).

Vehicle are devaluated through their use in proportion to operating kilometers, while their value will decrease as they become older, even without using. Particularly, passenger car loses its value rapidly as time passes. Therefore, the proportion of depreciation subject to use and subject to time may be assumed as follows: 50:50 for passenger car and 70:30 for others.

Depreciation subject to use is furthermore subdivided into two parts. It is assumed that two third of this cost depends on the accumulated driven kilometers and one thirds are affected by operating speed. Costs of use-related depreciation and time-relate depreciation is shown in Table 11 and Table 12, respectively.

Time related depreciation in the table presents daily and hourly depreciation cost which is depreciable amount divided by number of days and operating hours during life period.

#### 7. Capital Opportunity Cost (Interest)

This cost is not affected by use but accrues only as time passes and is determined by vehicle price, life period, salvage value rate and interest rate, using the following formula:

$$C = P (1 - r) F - P / n + i r P$$
  
F = i (1 + i)<sup>n</sup> / ((1 + i)<sup>n</sup> - 1)

Where,

- P: Economic cost of vehicle
- F: Capital recovery factor
- r: Salvage value rate

i : Interest rate

n: Durability (Vehicle life)

C: Capital opportunity cost

Interest rate is 12 % which is the rate adopted by the MTC's analysis and also to be used as the discount rate when calculating evaluation indices. Table 13 presents hourly capital opportunity cost. Total capital opportunity cost in the study area is the product of this cost and total number of vehicles-hours.

#### 8. Crew Cost and Overhead Cost

This cost is not affected by driven kilometer but is proportional to time. According to an interview survey to bus driveers, average annual wage of a bus driver is about US\$300 while that of a truck driver is US\$350, approximately 16% higher than bus driver's wage. Adding wages of assistants to this, annual crew cost per truck is estimated to be US\$450 (Table 14). Overhead cost of bus and truck transport business is assumed at 60% of crew cost.

#### 9. Aggregate VOC

Aggregate unit VOCs are summarized as shown in Table 15. To calculate total VOC in a network, firstly, operating speed of each link is obtained from the traffic assignment result, secondly, total distance-related cost is calculated by summing up the cost in each link and finally, time-related cost calculated separately using total vehicle-hours is added to the distance-related cost.

Source: Ministerio de Transporte y Infraestructura

Note: 1. The margin of refinary was considered as a percentage of the base price, as 19.6% for diesel, 29.55% for regular gasoline and 32.1% for super gasoline.

2. The price of the crude oil was the average price regulated by INE as of February 12 to March 11, 1988.

3. According to INE, for Freight, Insurance, etc, the values of Premium (PM), Sea freight (FTM), calculation of Sea Insurance, In transit Loss, Letter of Credit and Bank Charge are included.

4. For storage and port charges was taken from INE's data which includes the following: Entrance Cost, Calculation of in Terminal Loss and Terminal Margin.

5. Only the base price and IEC (Petroleum Consumption Tax) were taken from investigations done in several Gas Stations to calculate the regular and super gasoline.
