CHAPTER 5

WASTE AMOUNT FORECAST

5. FUTURE WASTE AMOUNT AND COMPOSITION FORECAST

5.1 Forecast Conditions

5.1.1 Types of Waste

This study will deal with the following types of waste:

- household waste
- commercial waste
- market waste
- institutional waste
- street sweeping waste
- river cleansing waste

5.1.2 Target Years

The years targeted for the forecast of waste amount and composition are as follows:

- 2005 for the first priority project
- 2010 for the master plan

5.1.3 Factors Affecting Waste Increase and Composition

Future waste generation and composition will be influenced by the following factors:

- social welfare and financial capacity of individual consumers/families
- industrial technology
- importation

It is difficult to forecast future waste generation and composition in Metro Manila due to the absence of data on past conditions. Nonetheless, the wastes of the Philippines should identify with the developing state of the country (e.g. GDP growth).

5.2 Forecast Future Waste Amount

5.2.1 Previous Studies

Solid waste amount and composition surveys in Metro Manila have been undertaken 5 times in the past. However, there have only been three surveys on waste generation rate: in 1982 and 1993, and by the JICA Study Team in 1997. Table 5.1 shows the results of the waste generation surveys. The waste trend established by the 1993 survey in Makati City largely differed from the results of the 1982 survey and the recent one conducted by the JICA Study Team.

Table 5.1Comparison of Household Waste Generation Rate in Metro Manila Based
on Recent and Previous Surveys

	SWM-JICA Study 1997		1982 *1	1993 *2
	Dry Season	Rainy Season		
High Income Areas	503	497	477	934
Middle Income Areas	467	435	202	352
Low Income Areas	352	336	168	737

*1: Norconsult A.S. MMSWMS, 1982

Samples were collected at the curbside of residences

*2: The Makati Waste Characterization Project (MWCP) conducted in 1993 by a local consultant hired by the Makati Mayor. In the study, waste was divided as follows:

- 1. Residential sector (high, middle and low income by barangay)
- 2. Institutional sector
- 3. Commercial sector
- 4. School sector
- 5. Market sector
- 6. Hospital sector
- 7. Industrial sector (barangay Pateros)

5.2.2 Waste Generation Rate

To determine the relationship between GDP and waste generation, the increase in welfare services was taken into account. Although a direct connection is not anticipated, some aspects indicating further analysis may be identified.

GDP increase is expected to have a larger impact on waste generation per capita of developing countries than of developed countries. Also, at a certain welfare level, increase in GDP remarkably changes the composition of waste.

The future waste generation rate (WGR) of Metro Manila was forecast based on the results of the study conducted by the JICA Study Team. The WGR obtained through this study showed a 2% annual increase when compared with the results of the 1982 study. GDP growth correlates with changes in waste volume. The factors that define the relationship could not be determined, however, due to sharp fluctuations in the GDP of the Philippines since 1982. In comparison with cities of other developing countries, Metro Manila has a low WGR. It is assumed to increase in the future though, and this study assumes that the increase will be as before, at 2% per annum.

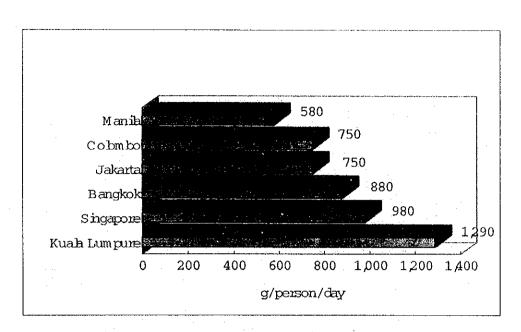

Figure 5.1 Comparison with MSW Generation Rate of Developing Countries

With the exception of household waste, the WGR of other waste types will be significantly influenced by economic developments and is estimated to increase together with the increase in household waste generation units. The increase in WGR is estimated to be similar with the increase in household waste generation units, at 2% per annum. Based on this, household UWG as of 2010 was estimated at 542 g/person/day.

				1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 -		1. A.

Total	9,454,049	11,063,000	12,826,000	14,583,000

Table 5.3Population Estimates

2) Other Units

Commercial shops, market stalls, government and public offices are assumed to increase at the same rate with the population. Street sweeping and river cleansing services currently cover principal areas, and will be maintained in the future.

Forecast Waste Generation Amount

The future waste generation amount in Metro Manila was calculated based on the number of generation source units and the unit waste generation rate, using the equation below. The results indicate that the waste generation amount in Metro Manila in 2010 will be 10,300 tons/day, twice as much as present.

[Waste Generation Amount] = [Waste Generation Rate] × [Unit Number]

 Table 5.4
 Waste Generation Amount (unit : ton/year)

	Household Waste	Commerci	al Waste	Market Waste	Institutional Waste	Street Sweeping Waste	River Cleansing Waste	Total
		Restaurant	Other Shops			· · · · · · · · · · · · · · · · · · ·

5.3 Waste Composition Forecast

5.3.1 Physical Composition Forecast

Waste composition is assumed to change in consideration of new products in the market and a different consumption pattern.

Table 5.5 compares the MSW composition data of previous surveys and the data obtained from the WACS.

	1982	1993	199	07	1994

Apparent Specific Gravity (kg/m ³)	-		180	180	-

Table 5.5 Comparison of MSW Composition Data

Wastes in Metro Manila contain a high proportion of paper and plastics, as is the case in developed nations. Also, because of progressive urbanization, the ratio of grass and wood has decreased. Taking this into account, the waste composition forecast particularly focused on the rate of increase in paper and plastics, and the rate of decrease in grass and wood (see Table 5.6). The waste composition in Metro Manila is assumed to undergo the following changes:

- The rate of increase in paper and plastics will be 19% and 17%, respectively.
- The rate of grass and wood will fall to 5% due to reduced urban vegetation
- Only minor changes are observed in other constituents

	*		unit: %

Table 5.6Forecast MSW Composition

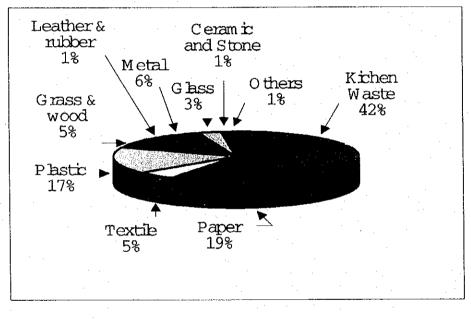

Figure 5.2 Waste Composition in 2010

5.3.2 Forecast Calorific Value

LCV of the Physical Composition of Each Waste Category

The calorific values of the following were measured in the WACS:

- combustibles from 8 generation sources, i.e. residential areas (high, middle, low income), markets, commercial areas (restaurants, etc.), institutions, roads
- each combustible item from middle income residential areas

The calorific value of waste differs according to physical composition, moisture content, combustible matter and ash contain, and the ratio of combustible waste and ash depends on the physical changes that occur. Table 5.7 shows the data on mixed combustibles as surveyed through this study and in 1982.

		1997 JICA Study		1982
		Household	MSW	
Moisture Content	(%)	45.76	45.00	42.6
Combustible Content	(%)	45.89	46.65	33.8
Ash Content	(%)	8.35	8.35	23.6
Lower Calorific Value	(kcal/kg)	1,686	1,709	1,843

 Table 5.7
 Comparison of Moisture, Combustible, Ash Content and LCV

The 1997 data obtained by the JICA Study Team shown in the table are weighing average figures of mixed wastes, taking the waste generation ratio by each category into account. The moisture content ranged between 30% - 55%.

The lower calorific value was high, mainly because of the high proportion of paper and plastics in the waste. However, the value is lower than in 1982. The following are pointed from data between in 1982 and 1997;

- Increase of moisture content from 1982 to 1997 is accurately accompanied by a decrease of calorific value.
- On the other hand, an increase of combustibles contents specially high calorific value plastic content is accompanied by a decrease in calorific value and not, as expected, an increase.
- . The calorific value was estimated as follows;

The higher calorific value (HCV) in dry base of each combustible component of waste from middle income residential areas was also measured to calculate the lower calorific values (LCV), as shown in Table 5.8.

 Table 5.8
 HCV in Dry Base and LCV in Wet Base of Combustible Wastes

Combustible Wastes	HCV in Dry Base (kcal/kg)	LCV in Wet Base (kcal/kg)
Kitchen Waste	3,572	482
Paper	3,672	2,492
Textile	4,198	1,852
Plastic	6,566	3,406
Grass & Wood	3,555	1,139
Leather & Rubber	8,401	7,343

The LCV of wastes was calculated as follows:

 $LCV = (Rga^{*1}*482 + Rpa^{*2}*2,492 + RT^{*3}*1,852 + RPI^{*4}*3,406 + RGr^{*5}*1,139 + RL^{*6}*7,343)/100$

where,	
	ratio of kitchen waste in wet weight (%)
$Rpa^{*2} = RT^{*3} =$	ratio of paper in wet weight (%)
	ratio of textile in wet weight (%)
RPl^{*4} =	ratio of plastic in wet weight (%)
$RGr^{*5} =$	ratio of grass and wood in wet weight (%)
RL^{*6} =	ratio of leather and rubber in wet weight (%)

The calorific value was calculated as 1,570kcal/kg in 1997. The difference between the

analysis and calculation was only 140 kcal/kcal which is a reliable figure. On the other hand, the calorific value was estimated as 1,455kcal/kg in 1982. The difference of an analyzed and calculated data was around 400 kcal/kcal.

	1997	1982
Analysis	1,709	1,843
Estimation	1,570	1455
Difference	139	388

5.9 Comparison calorific value between analysis basis data and estimation data(kcal/kg)

Lower calorific value forecast

Using the above mentioned formula, the future MSW LCV is estimated by multiplying the LCV in Table 5.8 by the ratio of the future physical composition shown in Table 5.6. In case a separate collection system will not be introduced, the LCV of mixed waste is estimated as shown in Table 5.9.

Table 5.9 Lower Calorific Value Forecast

Year		Lower Calorific Value (kcal/kg)	
	1997	1,570	
	2005	1,597	
	2010	1,661	

5.4 Future Waste Stream

5.4.1 Forecast Conditions

Recycling

The recycling rate in Metro Manila was set as shown in the table below.

		1998-2004	2005	2010
Source Recycling	by NGO	4	6	6
	by LGU	0	0	(2)*
Recycling by collecto	rs	1	0	0
Recycling by waste p	ickers	1	0	0
Recycling in recycling center		0	0	2*
Recycling in composi		0	1	2
Total		6	7	10

* Recyclable materials collected by LGU will be hauled to recycling plant for segregation

Source Recycling

The recyclable amount at the source varies according to changes in waste quality, socioeconomic activities, and policies to promote recycling activities. As stated in section c (Future Waste Composition), there will be no significant changes in the quality of waste in Metro Manila in the future. However, the recyclable amount might increase if separate discharge at the source is implemented in the future.

Taking this into account, the recyclable amount at the time of discharge is set as follows:

- The current recycling rate is 6% according to the WACS results.

- The rate of recyclable materials recovered by NGOs at discharge sources is 4%.
- . The rate of recyclable materials recovered by waste collectors is 1%.
- The rate of recyclable materials recovered by waste pickers is 1%.

The recyclable waste volume is considered to increase with the waste generation amount, and the increase rate by 2005 will be set as in the present. Recovery of recyclable materials by waste collectors and pickers will be terminated from 2005 as a result of improved collection efficiency and closure of open dumpsites. Also, the commencement of resource-recovery at the discharge source will enable the segregation of recyclable materials recovered by collectors and waste pickers at the discharge source. The satisfactory execution of segregated collection is predicted to increase the recycling rate, and the rate of recycling at generation sources as of 2010 was set at 8%, 2% higher than the present.

The collection of recyclable materials at discharge sources will be entrusted to NGOs, as in the present. To supplement NGO recycling activities, the collection of a part of the generated recyclable materials will be done by the LGUs after 2010. Collected recyclable materials will be segregated at the recycling center.

1) Recycling at the Recycling Center (RRC)

From 2010, a part of the recyclable materials segregated from other wastes at discharge sources will be collected by LGUs, and segregated again at the recycling center. This study assumes that recyclable materials make up 2% of the generated waste amount.

2) Recycling in Composting Plant (RCP)

From 2005, a part of the market waste will be recycled by composting. The amount of market waste for composting will be gradually increased: 5% in 2005 and 58% in 2010. The compost volume that would result from the 5%, however, would only be equivalent to 1% of the total waste generation volume. For 2010, the project aims to actually recycle 2% of the total waste generation volume out of 58% of market waste.

Table 5.11Recycling Rate and Amount by Composting

	2005	2010
Recycling Rate	1%	2%
Composting Amount	14t/day	206t/day
Market Waste Amount	24.72t/day	356t/day
	(5% of market waste)	(58% of market waste)

According to the WACS results, the market wastes (58%) for composting in 2010 will be made up of organic materials.

Self-disposal (Collection Area)

The residential environment significantly affects self-disposal. The population of Metro Manila is predicted to further increase and, as a consequence, housing spaces are presumed to significantly change by district. The housing space per person in areas urbanized to a certain extent is assumed to decrease, as opposed to the surrounding areas which are less urbanized.

In consideration thereof, the self-disposal amount in collection areas was set at 5% of the generation amount, about the same as in the present.

=	G*0.05 where,	SD	:	Self-disposal amount (t/day)
		G	:	Generation amount (t/day)
		0.05	:	Self-disposal rate

Discharge

SD

The waste discharge amount is obtained as follows:

D	=	G - SR - SD where,	D	=	Discharge amount (ton/day)
			G	=	Generation amount (ton/day)
		• •	SR	<u></u>	Source recycling amount by
					LGU (ton/day)
		· · · ·	SD	=	Self-disposal amount (t/day)
	· · · · ·				e de la companya de l

Collection

The present collection ratio in the entire Metro Manila is approximately 73%. This is expected to increase to 80% in 2005 and 90% in 2010 as a result of the planned expansion of service area coverage. Table 5.12 shows the future collection ratio by LGU. These collection ratios were established with due consideration of areas, e.g. squatter areas, where collection is difficult to implement.

 $C = D \times [collection coverage (\%)] \div 100$

Table 5.12

Collection Coverage (%)

	and the second

Final Disposal

The final dis	sposa	al amount is calculated as follows:
FD	=	C - RRC - RCP + DHW
where,		
FD	:	Final disposal amount (t/day)
С	:	Collection amount (t/day)
RRC	:	Recycling amount in recycling center
RCP	:	Recycling amount in composting plant
DHW	:	Direct haulage waste amount (t/day)

5.4.2 Future Waste Stream

The future waste streams are presented in Table 5.13 and 5.14 and Figure 5.3 and 5.4. Five (5) percent of the waste generation amount is self-disposed either by burning in open fields or burying; five (6) percent are recycled (bottles, cans, paper, plastics) by NGOs. The rest are discharged into a landfill. Due to spatial restrictions (e.g. inaccessibility), however, some (9%) of the generated waste amount are not collected.

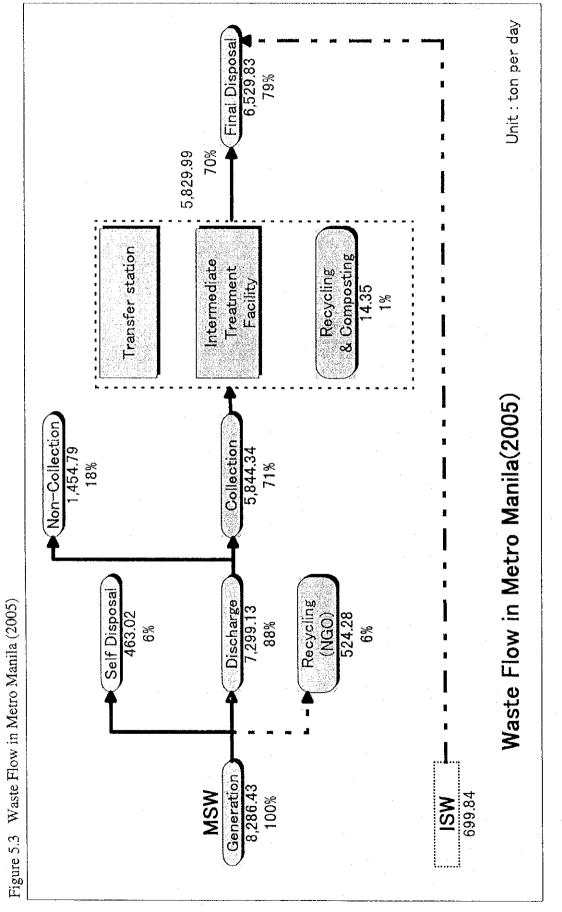

The amount of waste to be collected in 2010 is estimated to reach 8,400 tons/day. The collected waste amount will be disposed of into a landfill. But for a better solid waste management system, a combination of appropriate technical systems, e.g. transfer station for haulage efficiency and intermediate treatment facilities for waste volume reduction and resource-recovery, will be adopted. The amount of non-hazardous industrial waste to be disposed in the future is estimated at 860 tons/day.
