4.3 Microscopic Demand Forecast

4.3.1 Method of Microscopic Demand Forecast

For Dar es Salaam, Arusha, and Moshi, the microscopic demand forecast for the future decade (2001-2010) was made by extrapolating the actual power demands for the past decade (1991-2000) for the existing substations. The actual demands in the past include not only the increases in demand due to the ordinary economic growth but also extraordinary factors such as the electrification of unelectrified villages and the expansion of large industrial plants. Looking at the 2010 demand forecast, there are unrealistic capacities for single substations. For example, in Table 4.7, City Center S/S 52.5 MVA (11 kV) are unusually large capacities. Realistic capacity of substations is described in a later chapter. With the increase in demand, feeders from existing substations shall be relocated, branched, and shared by newly installed substations. Namely, the total forecast demand including newly installed substations is regarded as equivalent to the total value obtained by extrapolation of the existing substations. With respect to New Oysterbay S/S which is to be installed in Dar es Salaam, it is expected that comparatively large demands, such as from the American Embassy under construction, will come soon, hence suitable corrections have been added to them. As for the other substations to be installed in the future, such as Kitunda, Magomeni, Mburahati, Yombo, TOL and Tandika, they are not included in the demand forecast but their values are extrapolated as mentioned above.

In the demand forecast for each individual substation, maximum power for the past ten years (1991-2000) was picked up from the operation log for each 11 kV feeder, and growth rate was calculated and extrapolated to forecast future demand. Since the operation log includes 11 kV feeder loss and low-voltage line loss, it cannot be said that the demand forecast represents a pure demand. At present, however, it is the only record of maximum power that is the closest to the receiving end. And since the value indicates the very capacity that passed through the transformer, it shows the capacity and time of installation of a new transformer at a glance. Where the records were unreliable or there were too few recorded items because the substation was put into operation in recent years, maximum power was forecast using growth rates for the three cities (annual rates of maximum power up until 2010) obtained by the macroscopic method described in 4.2. The values are shown below.

Dar es Salaam	6.7%
Arusha	9.2%
Moshi	8.8%

4.3.2 Actual and Forecast Maximum Power in Dar es Salaam

The actual and forecast maximum power obtained from the past operation logs for the substations in Dar es Salaam are shown in Table 4.6, Fig. 4.7.1, 4.7.2 and 4.7.3.

Different substations show different growth rates. Substations showing high growth rates include Kigamboni S/S(25%), Msasani S/S(15%), Mbezi S/S(11%), and FZ III S/S (9%). These substations supply new residential areas, resort hotel zones, shopping centers, industrial zones, etc. Tandale S/S shows a modest 4% growth rate, but its environs are growing.

The operation logs give maximum power in MW. The MW values converted in terms of MVA with the power factor taken into consideration are shown in Table 4.7.

*8 Mbezi is included by 3 Tegeta

Considerations in converting MW values in terms of MVA are as follows.

- As the power factor used for conversion, 80% was applied in all cases. This is because many substations were found operating with 80% power factor at the 11 kV feeder outlet or 33/11 kV transformer low-voltage side. At some substations, the power factor was about 90%. However, we adopted 80% to give allowance.
- The number of 11 kV feeders ranges from 3 to 8. The maximum power at a substation is smaller than the simple sum of maximum power of each feeder due to the diversity factor. However, for substations which had no overall transformer power flow data, the simple sum of feeders was adopted to be on the safe side.

CHAPTER 4 POWER SUPPLY AND DEMAND

4.3.3 Actual and Forecast Maximum Power in Arusha

In Arusha, 220 kV Njiro S/S meet the entire demand in Arusha.

Besides, Njiro S/S obtains power from both 220 kV and 132 kV systems. It receives 220 kV from Singida S/S and 132 kV from the power of the Pangani river system via Moshi. The forecast maximum power in 2010 is less than 100 MW. If the 132 kV transmission line between Kiyungi and Hale fails, one 220 kV transmission line and 220 kV transformer banks will be insufficient to meet the demand of Arusha and Kilimanjaro. Therefore, more transformer banks in Njiro S/S will be necessary. The towns are well planned and there are a few long-distance feeders. Therefore, the voltage problems seem not so serious as in Moshi.

From the records of maximum power in the past in Arusha, future maximum power was forecast. The results are shown in Table 4.8 and Fig. 4.8. Figures with power factor added and expressed in MVA are shown in Table 4.9. It is Mt. Meru S/S (5 MVA x 2) in city center that is the substation showing the highest growth rate -12%. The substation that shows the second highest growth rate is Themis S/S (5 MVA x 1), though the MVA value is not so large.

4.3.4 Actual and Forecast Maximum Power in Moshi

The actual and forecast maximum powers are shown in Table 4.10 and Fig. 4.9. Figures with power factor added and expressed in MVA are shown in Table 4.11. In Moshi, there were substations which had no satisfactory data or indicating meters, hence many of the substations were forecast using growth rate obtained by the macroscopic forecast.

Concerning Nymba ya Mung P/P(5 MVA x 1) and Lawate S/S(2.5 MVA x 1), accurate demand could not be grasped since they were put into operation only recently. Therefore, the growth rate of 8.8% obtained by the macroscopic forecast was used to forecast the future demand for them. Therefore, development plans for them should be formulated after actual demands in the several years are grasped. With the current load conditions, the present transformer capacity is sufficient to meet the demand for several years to come. The substations which supply city center and which had growth data were Boma Mbuzi S/S(5 MVA x 2) and Trade School S/S(5 MVA x 1), which showed growth rate of less than 10%.

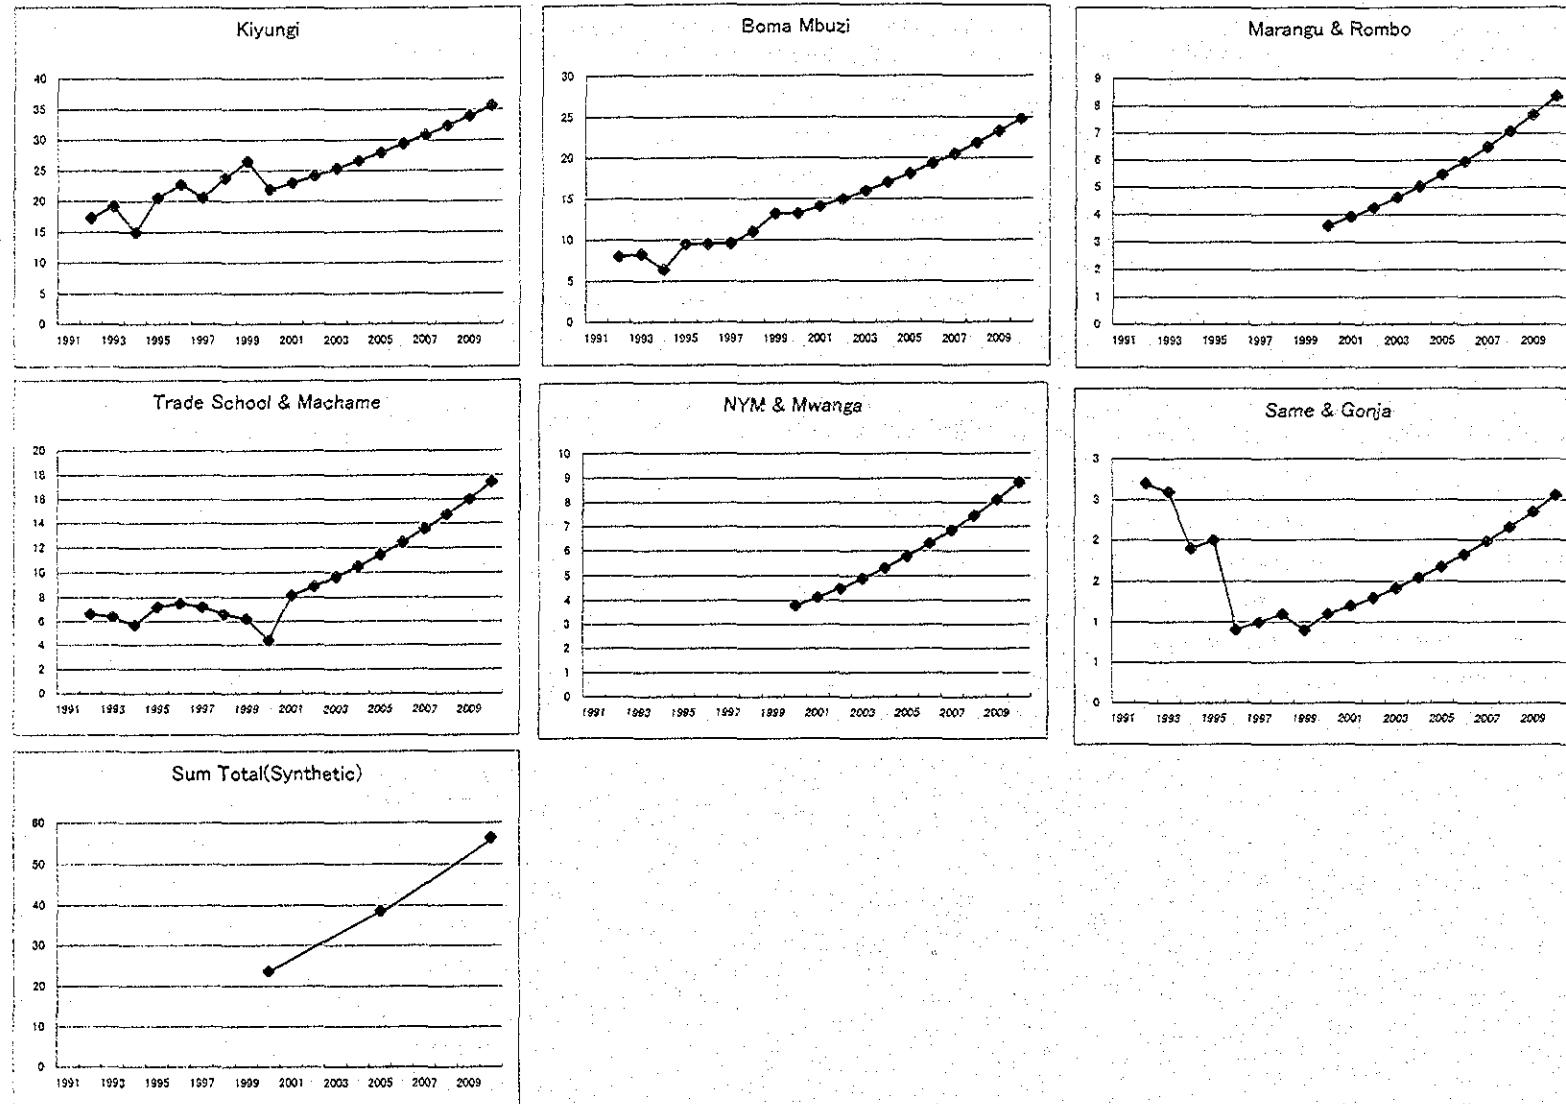

Fig. 4.9 Past and Future Max. Power at the Substations in Moshi (MW)

4.4 Summary of Demand Forecast

There are two methods of demand forecast—the macroscopic method described in 4.2 and the microscopic method described in 4.3. The results obtained by these methods are compared in Table 4.12. Values obtained by macroscopic forecast are purely values on the demand side and do not include losses. Microscopic forecast values are values measured at distribution substation, hence they include the 11 kV feeder loss and low-voltage line loss. Naturally, therefore, the latter is somewhat larger than the former. Looking at the year 2010, the difference is 4.4% for Dar es Salaam, 6.9% for Arusha, and 10.3% for Moshi in 2010. TANESCO's gross power system loss is said to be between 15% and 20%. Considering that the distribution loss is several percentage points lower than the gross power system loss, it may safely be said that the macroscopic and microscopic forecast values agree very well.

Table 4.12 Comparison by means of Forecast Methods in 2010 (MW)

	Macro Forecast (From GDP)	Micro Forecast (From Substation Load)
	Max. Demand	Max Power
Dar es Salaam	475.2	495.9
Arusha	79.7	85.2
Moshi	53.4	58.9

Source

Table 4.5

Table 4.6, 4.8 and 4.10

From the reason mentioned above, the Team used the microscopic forecast values which are several percentage points larger than the macroscopic forecast values as the forecast demand based on which to decide substation capacity in the future. The values for determining substation capacities in the three cities are as shown in Tables 4.7, 4.9, and 4.11.
