

**CHAPTER 12**  
**FUTURE TRAFFIC DEMAND**

## CHAPTER 12 FUTURE TRAFFIC DEMAND

### 12.1 General Methodology

The overall demand for traffic movement has been formulated using a combination of data from the traffic surveys (Chapter 10) and economic growth projections for Nicaragua (Chapter 11). The way in which traffic routes on the highway network is forecast using the traffic assignment model JICA STRADA<sup>(1)</sup>.

The key modules in JICA STRADA that were used in this study are:

|                                |  |
|--------------------------------|--|
| <b>Network Editor:</b>         | to build, modify and test highway networks     |
| <b>OD Matrix Manipulator:</b>  | to construct traffic demand matrices           |
| <b>Incremental Assignment:</b> | to assign traffic to the network               |
| <b>Highway Reporter:</b>       | to view traffic volumes and network statistics |

### 12.2 Highway Network

The base year (2002) highway comprises 83 nodes and 113 links and is shown as Figure 12.2.1. Study roads are shown as red.

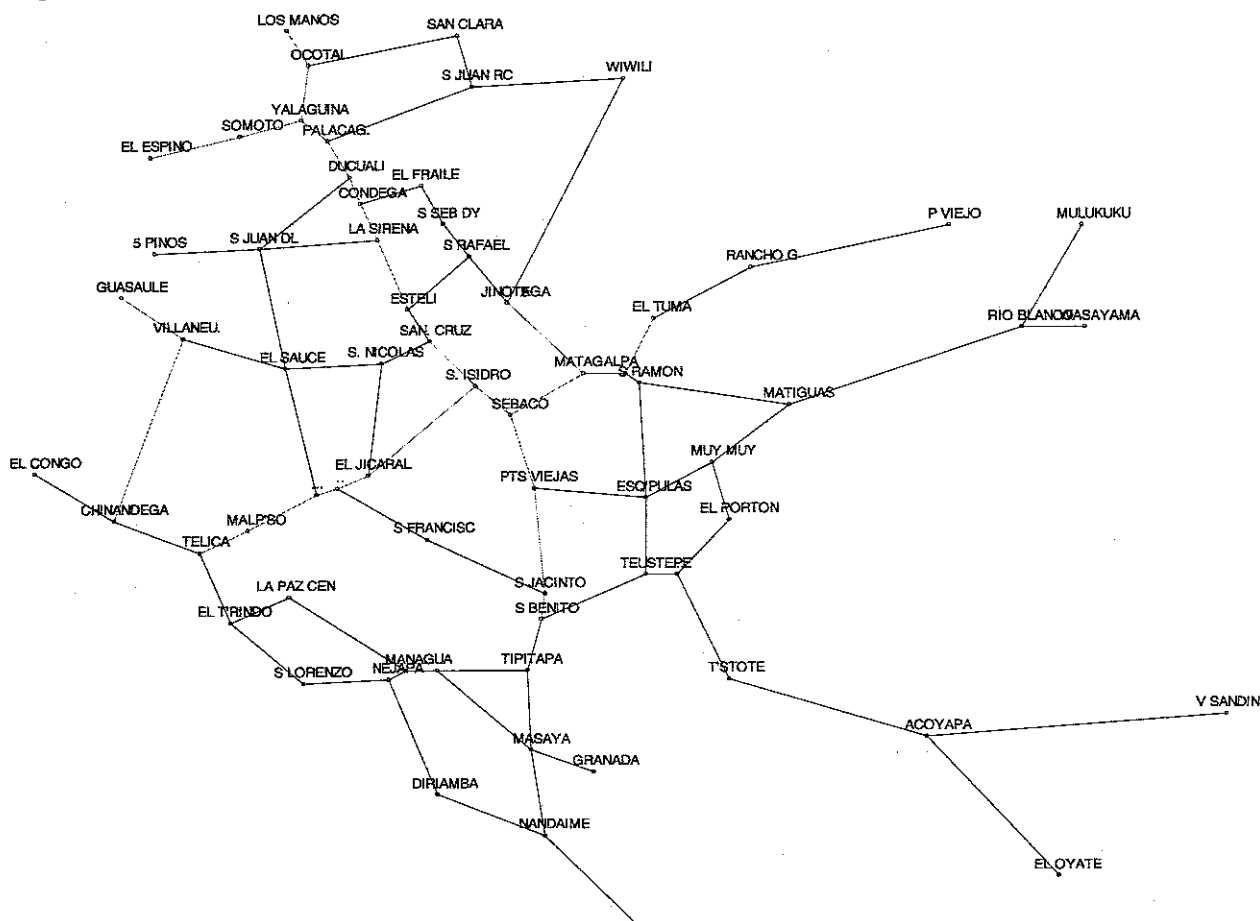

Figure 12.2.1 Base Year Highway Network

(1) JICA STRADA Version 2, International Cooperation Data Service Co., Ltd, JICA, 1997 - 2000

Figure 12.2.2. below shows the major roads on the highway network along with place name.

**Figure 12.2.2 Base Year Network, Major Roads**

All links were coded as to length, maximum velocity, capacity and volume-delay function (QV type 1 was used in each case). There is currently little congestion on the study roads. Six traffic modes were specified: car(1), utilities/pick-ups(2), buses(3), light goods(4), medium goods(5), and heavy goods(6). Traffic zones (1 to 45) are connected to the network at the nodes listed in Table 12.2.1.

### 12.3 Base Year Matrices

Base year (2002) matrices were constructed from the origin-destination interviews, factored to the traffic counts recorded in June 2002. For modes 1 through 3, the following procedure was adopted. All interviews were entered by site into nine separate matrices. For each mode and each site the matrix was factored to the site count for that mode of traffic. Sites were combined for each mode and double (or treble) counted trips removed. For modes 4 through 6, interview data were entered for each mode into five separate matrices representing: construction(1), industry(2), other primary(3), vacant/other(4), and agriculture(5). Because the matrices of interview data were small for each commodity type, they were combined by mode and calibrated against the traffic counts at the nine sites.

Table 12.2.1 Zone Connectors

| Zone | Name                   | Node Connector | Zone | Name                | Node Connector |
|------|------------------------|----------------|------|---------------------|----------------|
| 1    | Ocotol                 | 104            | 24   | El Sauce            | 601            |
| 2    | San Fernando           | 102            | 25   | El Jicarol          | 604            |
| 3    | Honduras via Los Manos | 101            | 26   | Malpaisillo         | 608            |
| 4    | Yalaguina              | 405            | 27   | Leon                | 605            |
| 5    | Honduras via El Espino | 404            | 28   | La Paz Centro       | 606            |
| 6    | Quilali                | 103            | 29   | Managua             | 701            |
| 7    | Wiwili                 | 201            | 30   | Masaya              | 801            |
| 8    | R.A.A.N.               | 1601           | 31   | Carazo              | 1001           |
| 9    | La Cruz del Rio Grande | 1503           | 32   | Granada             | 901            |
| 10   | La Dalia               | 1108           | 33   | Rivas               | 902            |
| 11   | Matagalpa              | 1103           | 34   | Costa Rica          | 1701           |

| 23   | Sebaco                 | 1102           |      |                     |                |

#### 12.4 Base Year Traffic Estimates

The base year validation is as shown in Table 12.4.1. Note that the model is not valid for roads other than the study roads.

The base year 12-hour matrices were factored to AADT volumes in accordance with the data set out in Chapter 10. These matrices were assigned to the network and the resultant traffic estimates are shown in Figure 12.4.1. Network data for 2002 are set out in Table 12.4.2.

**Table 12.4.1 Base Year Validation, 12-hour Vehicle Flows, June 2002**

| Site  |             | Car/Taxi | Utilities | Buses | Light Goods | Medium Goods | Heavy Goods | Total |
|-------|-------------|----------|-----------|-------|-------------|--------------|-------------|-------|
| 1     | Observed    | 255      | 317       | 286   | 133         | 158          | 259         | 1408  |

| Medium Goods (5) | 1731                 | 107714             | 62.2                         | 726                | 148.4                           |
| Heavy Goods (6)  | 1479                 | 88568              | 59.9                         | 546                | 162.2                           |
| Total            | 20103                | 1243160            | 61.8                         | 10982              | 113.2                           |

## 12.5 Forecast Year Traffic

Forecast traffic demand matrices have been prepared for three years (i.e., 2003, 2010 and 2020) using the factors derived in Chapter 11. In the traffic surveys, no interviews were carried out on NIC.5 and so trips were added to the validation matrices between Zone 10 (La Dalia) and Zone 11 (Matagalpa) to match traffic counts taken by MTI in 2001. The trip totals in each forecast matrix are as summarised in Table 12.5.1.

**Table 12.5.1 Forecast Year AADT Totals by Mode**

| <i>Vehicles/ Year</i> | <i>2003</i> | <i>2010</i> | <i>2020</i> |
|-----------------------|-------------|-------------|-------------|
| Cars                  | 2493        | 3711        | 6521        |
| Pick-ups              | 5006        | 7351        | 12811       |
| Buses                 | 1523        | 1939        | 2654        |
| Light Goods           | 1533        | 2481        | 4136        |
| Medium Goods          | 889         | 1432        | 2412        |
| Heavy Goods           | 581         | 669         | 1539        |
| Total                 | 12028       | 17613       | 30073       |

Figures 12.5.1, 12.5.2 and 12.5.3 show traffic assignments for the three forecast years. Network statistics are shown in Table 12.5.2.

**CHAPTER 13**  
**EVALUATION OF TRAFFIC FORECASTS**

## CHAPTER 13 EVALUATION OF TRAFFIC FORECASTS

### 13.1 General Methodology

The traffic benefits that would result from disaster prevention measures are evaluated by calculating the dis-benefits to traffic of a disaster occurring. It is assumed that at each site a disaster would result in the closure of that particular link in the network and the need for traffic to re-route. When traffic re-routes to avoid the closed link it potentially incurs two types of dis-benefit:

- i) increased vehicle operating costs due to additional travel distance; and
- ii) increased passenger time costs.

These two parameters are evaluated by the JICA STRADA model in aggregate over the network for each vehicle mode in the form of vehicle-kilometres and vehicle-hours. These are then converted to monetary costs using the parameters set out in Table 11.3.1, which are expressed as the benefits of undertaking disaster prevention measures.

The costs of disaster prevention measures are expressed in terms of the capital cost of works (assumed to be incurred in 2003) and the continued maintenance cost of the link. The costs of temporary prevention measures are assumed to recur every three years. Permanent measures incur a single capital cost with annual maintenance costs thereafter.

The benefit flow however is not guaranteed to occur, because a disaster may not strike even if no preventative measures are taken. That is, the probability of a disaster occurring will have an affect on a benefit stream. Preliminary engineering inspections of the sites have resulted in two parameters being used to calculate this affect and are as follows:

- i) The maximum life of a road if no preventative measures are taken. This varies from 1 to 20 years and reflects the risk of a disaster occurring. Note that benefits only accrue after the lifetime of a road has ended.
- ii) An indicator of the stability of a slope or bridge foundation that varies from 70 to 100. This score is used to factor down benefits, which then accrue each year after disaster prevention works have been implemented.

An example calculation sheet for evaluating costs and benefits is shown in Figure 13.1.1.

| Average B/C  |                           | 1.5                       |        | Cost-Benefit Analysis |         |                         |                             |  |
|--|---------------------------|---------------------------|--------|-----------------------|---------|-------------------------|-----------------------------|--|
| Site No  | Link 7                    | A-Node                    | 405    | B-Node                | 404     | Base Case               |                             |  |

Disaster sites were evaluated by removing the relevant link identified in Table 13.2.1 and performing a traffic assignment. Figure 13.2.2 shows an example for Sites 28 through 34 located on Link 94, which is the road between Matagalpa and Jinotega. A disaster in 2010 is forecast to result in the traffic flows as shown below.

Figure 13.2.2 Forecast AADT Volumes, 2010, No Link 94

Network statistics for each vehicle type were extracted from JICA STRADA for the years 2003, 2010 and 2020 and input into the evaluation sheet. Data for intermediate years were estimated by linear interpolation. Benefits for years after 2002 were held constant at 2002 values. Benefit-to-cost ratios for each site were calculated and are shown in Table 13.2.2 and Figure 13.2.3.

Figure 13.2.3 Cost/ Benefit Ratios of Disaster Sites (Log-scale)

**Table 13.2.2 Benefit-to-Cost Ratio by Disaster Site**

| Site | Benefit-to-Cost Ratio | Site | Benefit-to-Cost Ratio |
|------|-----------------------|------|-----------------------|
| 1    | 137                   | 29   | 6                     |
| 2    | 153                   | 30   | 10                    |
| 3    | 1720                  | 31   | 14                    |
| 4    | 1240                  | 32   | 21                    |
| 5    | 365                   | 33   | 62                    |
| 6    | 1155                  | 34   | 25                    |
| 7    | 20                    | 35   | 18                    |

| 9    | 36                    | 37   | 11                    |
| 10   | 22                    | 38   | 23                    |
| 11   | 59                    | 39   | 16                    |
| 12   | 146                   | 40   | 115                   |
| 13   | 85                    | 41   | 85                    |
| 14   | 31                    | 42   | 35                    |
| 15   | 134                   | 43   | 85                    |
| 16   | 202                   | 44   | 71                    |
| 17   | 28                    | 45   | 200                   |
| 18   | 353                   | 46   | 245                   |
| 19   | 374                   | 47   | 197                   |
| 20   | 37                    | 48   | 361                   |
| 21   | 121                   | 49   | 70                    |
| 22   | 103                   | 50   | 55                    |
| 23   | 613                   | 51   | 112                   |
| 24   | 500                   | 52   | 436                   |
| 25   | 1001                  | 53   | 69                    |
| 26   | 2083                  | 54   | 730                   |
| 27   | 238                   | 55   | 488                   |
| 28   | 18                    |      |                       |

It has not been possible to carry out all the sensitivity tests with lower levels of traffic. Table 13.2.3 shows the comparison of benefit-to-cost ratio for eight sites for the Base Case and sensitivity test levels of traffic. The benefit-to-cost ratios remain relatively high, even under lower-growth assumptions for traffic.

**Table 13.2.3 Sensitivity Tests on Benefit-to-Cost Ratio**

| Site Number | Benefit-to-Cost Ratio |             |
|-------------|-----------------------|-------------|
|             | Base Case             | Sensitivity |
| 2           | 153                   | 111         |
| 17          | 28                    | 20          |
| 23          | 613                   | 463         |
| 24          | 500                   | 378         |
| 25          | 1001                  | 757         |
| 36          | 14                    | 10          |
| 37          | 11                    | 7           |
| 38          | 23                    | 16          |

### 13.3 Incorporation of Risk

Whilst the benefits reported in Section 13.2 are useful in preparing priorities for investment, they cannot be considered as *absolute* values. This is because at this stage the element of risk has not been considered. The benefits above all assume that without countermeasures, a disaster would strike by the end of the year 2003. This is extremely unlikely, and furthermore the risk element varies from site to site. This factor will be incorporated in the next stage of work.

**CHAPTER 14**  
IDENTIFICATION OF  
DISASTER PREVENTION SPOTS

## CHAPTER 14 IDENTIFICATION OF DISASTER PREVENTION SPOTS

### 14.1 General

The disaster critical spots identified in Chapter 6 of the Study require urgent, temporary or permanent countermeasures so that they can be transformed into disaster prevention spots. These spots are identified using various factors. The data used for designating a disaster critical spot are contained in chapters 8 to 13 and are as follows:

#### <Chapter 8>

- Hydrological survey: Evaluation of the progress regarding bridge foundation scouring
- Geological survey: Evaluation of the progress regarding rock weathering or collapse

#### <Chapter 9>

- Environmental survey: Evaluation of environmental impacts

#### <Chapter 12>

- Future traffic demand: Traffic forecast until the year 2020

#### <Chapter 13>

- Benefit-to-cost ratio: Evaluation of benefits and costs

It is difficult to designate a point a disaster critical spot based on economics only, since there are some spots where there are low traffic volumes. Low means traffic flows of less than 1000 vehicles AADT. Therefore, when evaluating roads and road sections for disaster criticality, a broader approach that incorporates level of stability, traffic volume, environmental impacts, development potential, natural conditions, benefits, required level of restoration, etc. should be considered.

### 14.2 Characteristics of Disaster Critical Spots

The characteristics of the 55 disaster critical spots on the Study roads that were identified in Chapter 6 are shown in Table 14.2.1. The types of disaster, the evaluation score, the types of countermeasures, and the rough cost estimates are described in the table. For instance, the stability score for the spots numbered 40 and 42 on NIC.26 is the same (i.e., 71 points), and the countermeasure is also the same (i.e., re-cutting of slope surface). However, the rough cost estimate for the construction of No. 42 indicates that it is about eight times greater because of the larger scale of the disaster it experienced.

### 14.3 Selection and Prioritisation of Disaster Critical Spots

#### 14.3.1 Outline of Selection Techniques

As described in 14.2 above, the evaluation score of a disaster critical spot differs depending on the scale of a disaster. Moreover, note that it is very difficult to identify disaster prevention spots in terms of cost only. Therefore, it is necessary to create an evaluation index to assess overall importance. Therefore, in this Study, the selection of disaster prevention spots is carried out using the Analytic Hierarchy Process (hereafter referred to as "AHP"). AHP is a multi-criteria decision-making technique that assigns numerical values (or weights) to various types of evaluation criteria. AHP was applied to select 30 disaster-prevention spots from the 55 disaster critical spots. The hierarchical decision-making structure of AHP uses the "evaluation criteria" of "purpose" and "alternative spots" (see Figure 14.3.1).

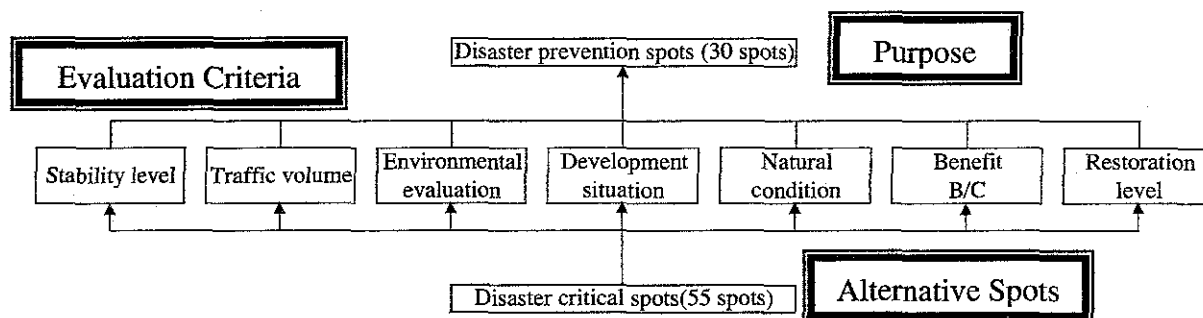

Figure 14.3.1 AHP Structure

Table 14.2.1 Characteristics of Disaster Critical Spots

| Serial Number of Disaster Critical Spot | Objective Road | Type of Disaster | Score | Type of Countermeasure                    | Cost (US\$1,000) |
|---|----------------|------------------|-------|---|------------------|
| 1                                       | NIC.1          | R.F.             | 70    | Barrier with gabion wall                  | 253              |
| 2                                       | NIC.1          | R.F.             | 78    | Prevention net                            | 236              |
| 3                                       | NIC.1          | Bridge           | 90    | Gabion mat                                | 25               |
| 4                                       | NIC.1          | Bridge           | 100   | Gabion mat                                | 2                |
| 5                                       | NIC.1          | Bridge           | 90    | Gabion mat                                | 65               |
| 6                                       | NIC.1          | Bridge           | 100   | Gabion mat                                | 12               |
| 7                                       | NIC.1          | R.F.             | 84    | Prevention net                            | 812              |
| 8                                       | NIC.1          | R.C.             | 72    | Prevention net                            | 315              |
| 9                                       | NIC.1          | R.C.             | 72    | Prevention net                            | 364              |
| 10                                      | NIC.1          | R.C.             | 72    | Recutting + Shotcrete                     | 1,772            |
| 11                                      | NIC.1          | R.C.             | 78    | Recutting + Shotcrete                     | 639              |
| 12                                      | NIC.1          | R.C.             | 76    | Recutting + Shotcrete                     | 184              |
| 13                                      | NIC.1          | R.C.             | 74    | Recutting + Shotcrete                     | 385              |
| 14                                      | NIC.1          | R.F.             | 76    | Prevention net                            | 456              |
| 15                                      | NIC.1          | R.C.             | 73    | Recutting + Shotcrete                     | 197              |
| 16                                      | NIC.1          | R.C.             | 73    | Prevention net                            | 125              |
| 17                                      | NIC.1          | R.F.             | 70    | Recutting + Shotcrete                     | 175              |
| 18                                      | NIC.1          | Bridge           | 100   | Gabion mat                                | 4                |
| 19                                      | NIC.1          | Bridge           | 100   | Gabion mat                                | 2                |
| 20                                      | NIC.1          | R.C.             | 75    | Prevention net                            | 208              |
| 21                                      | NIC.1          | R.F.             | 73    | Recutting + Surface drainage + Vegetation | 116              |
| 22                                      | NIC.1          | R.F.             | 73    | Recutting + Shotcrete                     | 152              |
| 23                                      | NIC.3          | R.C.             | 74    | Recutting                                 | 70               |
| 24                                      | NIC.3          | R.C.             | 72    | Recutting                                 | 91               |
| 25                                      | NIC.3          | R.C.             | 80    | Recutting                                 | 35               |
| 26                                      | NIC.3          | Bridge           | 100   | Reconstruction wing wall                  | 3                |
| 27                                      | NIC.3          | R.C.             | 74    | Recutting                                 | 177              |
| 28                                      | NIC.3          | R.C.             | 70    | Recutting + Shotcrete                     | 174              |

| 31                                      | NIC.3          | S.S.             | 71    | R.E.C.V.                                  | 248              |
| 32                                      | NIC.3          | S.S.             | 90    | R.E.C.V.                                  | 191              |
| 33                                      | NIC.3          | S.S.             | 90    | R.E.C.V.                                  | 30               |
| 34                                      | NIC.3          | R.C.             | 72    | Recutting + Prevention net                | 133              |
| 35                                      | NIC.5          | R.F.             | 76    | Recutting + Surface drainage + Vegetation | 744              |
| 36                                      | NIC.15         | D.F.             | 70    | Gabion wall                               | 58               |
| 37                                      | NIC.15         | D.F.             | 70    | Gabion wall                               | 40               |
| 38                                      | NIC.15         | D.F.             | 70    | Dam                                       | 279              |
| 39                                      | NIC.15         | D.F.             | 70    | Dam                                       | 193              |
| 40                                      | NIC.26         | R.F.             | 71    | Recutting                                 | 56               |
| 41                                      | NIC.26         | R.F.             | 70    | Recutting                                 | 115              |
| 42                                      | NIC.26         | R.F.             | 71    | Recutting                                 | 446              |
| 43                                      | NIC.26         | R.F.             | 72    | Recutting                                 | 121              |
| 44                                      | NIC.26         | R.F.             | 70    | Recutting + Shotcrete                     | 159              |
| 45                                      | NIC.26         | Bridge           | 100   | Gabion mat                                | 36               |
| 46                                      | NIC.26         | R.F.             | 76    | Barrier with gabion                       | 44               |
| 47                                      | NIC.26         | R.C.             | 73    | Prevention net                            | 52               |
| 48                                      | NIC.26         | R.F.             | 72    | Recutting + Shotcrete                     | 60               |
| 49                                      | NIC.26         | R.C.             | 80    | Recutting                                 | 191              |
| 50                                      | NIC.26         | R.F.             | 85    | Recutting + Shotcrete                     | 748              |
| 51                                      | NIC.26         | R.C.             | 86    | Prevention net                            | 131              |
| 52                                      | NIC.26         | Bridge           | 90    | Gabion mat                                | 24               |
| 53                                      | NIC.26         | R.C.             | 71    | Prevention net                            | 364              |
| 54                                      | NIC.26         | Bridge           | 90    | Gabion mat                                | 5                |
| 55                                      | NIC.26         | Bridge           | 100   | Gabion mat                                | 9                |

Type of Disaster  
R.F. : Rock Fall  
R.C. : Rock Collapse  
S.S. : Slope Slide  
D.F. : Debris Flow  
Bridge : Scouring of Foundation

Type of Countermeasure  
R.E.C.V. Recutting + Embankment  
+ Counterweight  
+ Vegetation

### 14.3.2 Prioritizing Disaster Prevention Spots

The priority level for disaster prevention spots is decided in the two steps described below.

**1) First Step (Setting of Evaluation Criteria)**

**a) Stability Level**

The stability level of each spot is compared based on survey results. If the stability score is large, the priority is high.

**b) Traffic Volume**

The traffic volume for 2020 for each spot is compared. When the traffic volume is large, priority is high.

**c) Environmental Evaluation**

The environmental evaluation results of each spot are compared and when the score is small the priority is high.

**d) Development Potential**

The roadside development potential of each spot is compared. The spot of area where the development was completion is high priority.

**e) Natural Conditions**

Critical level is compared based on the results of the natural condition survey, which takes into account geology, hydrology, etc. When the critical level is large, the priority is high.

**f) Benefits (Benefit/Cost)**

B/C ratios are compared based on the countermeasure costs of the first phase of this Study. When the B/C is large, the priority is high.

**g) Restoration Level**

The level of difficulty of restoration is evaluated based on assuming the damage to be incurred by a disaster of maximum scale. When the difficulty level, which consists of restoration time, restoration yard spaces, necessity of special machinery, etc., is high the priority is high.

## 2) Second Step (Pair Comparisons of Evaluation Criteria)

### a) Magnitude and Definition of Importance

Magnitude and definition of importance are as shown in Table 14.3.1 before the pair comparison of evaluation criteria is carried out.

**Table 14.3.1 Magnitude and Definition of Importance**

| Magnitude of Importance | Definition             |
|-------------------------|------------------------|
| 1                       | Equal importance       |
| 3                       | Weak importance        |
| 5                       | Strong importance      |
| 7                       | Very strong importance |
| 9                       | Absolute importance    |

When importance is low, the magnitude uses a reciprocal number. For instance, when stability level is weakly more important than traffic volume, the magnitude is 3. On the other hand, the magnitude for traffic volume compared to stability level is 1/3.

### b) Magnitude of Pair Comparison

The magnitude of pair comparisons for evaluation criteria was decided based on feedback from MTI as shown in Table 14.3.2. Moreover, the comparison of alternative spots was decided based on the evaluation scores produced by the JICA Study Team.

**Table 14.3.2 Magnitude of Pair Comparison**

|                        | Stability level | Traffic volume | Environment evaluation | Natural condition | Benefit B/C | Restoration level | Development situation | Weight             |
|------------------------|-----------------|----------------|------------------------|-------------------|-------------|-------------------|-----------------------|--------------------|
| Stability level        | 1               | 3              | 5                      | 3                 | 7           | 3                 | 9                     | 0.36676            |
| Traffic volume         | 1/3             | 1              | 3                      | 1                 | 5           | 1                 | 7                     | 0.16733            |
| Environment evaluation | 1/5             | 1/3            | 1                      | 1/5               | 3           | 1                 | 7                     | 0.08395            |
| Natural condition      | 1/3             | 1              | 5                      | 1                 | 5           | 1                 | 7                     | 0.18000            |
| Benefit B/C            | 1/7             | 1/5            | 1/3                    | 1/5               | 1           | 1/5               | 3                     | 0.03826            |
| Restoration level      | 1/3             | 1              | 1                      | 1                 | 5           | 1                 | 7                     | 0.14303            |
| Development situation  | 1/9             | 1/7            | 1/7                    | 1/7               | 1/3         | 1/7               | 1                     | 0.02068<br>1.00000 |

The weight for each evaluation criteria is presented in Appendix-III.

## 14.4 Identification of Disaster Prevention Spots

The priority of disaster prevention spots, as identified by AHP based on the magnitude of pair comparison, is shown in Table 14.4.1. The feasibility of the highest ranking 30 spots should be examined in this Study.

Table 14.4.1 Disaster Prevention Spots

| Priority | Objective Road | Serial No. of Critical Spot | Type of Disaster | Type of Countermeasure                    |
|----------|----------------|-----------------------------|------------------|---|
| 1        | Nic3           | 26                          | Bridge           | Reconstruction wing wall                  |
| 2        | Nic26          | 45                          | Bridge           | Gabion mat                                |
| 3        | Nic1           | 6                           | Bridge           | Gabion mat                                |
| 4        | Nic1           | 19                          | Bridge           | Gabion mat                                |
| 5        | Nic26          | 55                          | Bridge           | Gabion mat                                |
| 6        | Nic1           | 18                          | Bridge           | Gabion mat                                |
| 7        | Nic1           | 4                           | Bridge           | Gabion mat                                |
| 8        | Nic3           | 32                          | S.S.             | R.E.C.V.                                  |
| 9        | Nic3           | 33                          | S.S.             | R.E.C.V.                                  |
| 10       | Nic26          | 50                          | R.F.             | Recutting + Shotcrete                     |
| 11       | Nic1           | 5                           | Bridge           | Gabion mat                                |
| 12       | Nic26          | 52                          | Bridge           | Gabion mat                                |
| 13       | Nic1           | 2                           | R.F.             | Prevention net                            |
| 14       | Nic3           | 25                          | R.C.             | Recutting                                 |
| 15       | Nic26          | 54                          | Bridge           | Gabion mat                                |
| 16       | Nic1           | 3                           | Bridge           | Gabion mat                                |
| 17       | Nic1           | 1                           | R.F.             | Barrier with gabion wall                  |

**PART B**

**FEASIBILITY STUDY**

**CHAPTER 15**  
**INTRODUCTION**

## CHAPTER 15 INTRODUCTION

### 15.1 General

In Part A of this Study, 30 disaster prevention spots were identified using a wide variety of selection criteria. In this part, or Part B, a Feasibility Study (hereafter referred to as the “FS”) is carried out on these prevention spots in the nine chapters (including this chapter) listed below.

- Chapter 15 Introduction
- Chapter 16 Basic Design Standards
- Chapter 17 Detailed Examination of Countermeasures
- Chapter 18 Construction Plan and Cost Estimates
- Chapter 19 Environmental Impact Assessment
- Chapter 20 Project Evaluation
- Chapter 21 Implementation Program
- Chapter 22 Management System and Operation
- Chapter 23 Conclusions and Recommendations.

In order to implement the FS, a thorough review of countermeasures is carried out based on detailed geological survey data, hydrological survey results, topographic data, and the environment impact assessment. As described in Chapter 14, the 30 disaster prevention spots were selected applying the evaluation criteria shown below.

#### ➤ **Stability Level**

Each spot was examined in the context of stability levels based on survey results.

#### ➤ **Traffic Volume**

Forecast traffic volumes of spots for the years 2010 and 2020 were compared.

#### ➤ **Environmental Evaluation**

Each spot was evaluated against a series of environmental items.

#### ➤ **Development situation**

The potential development of roadside areas of each spot was compared.

#### ➤ **Natural Conditions**

The critical levels of spots were compared applying the natural condition survey results and geological, hydrological and topographic data for the rainy season.

#### ➤ **Benefit/Cost (B/C)**

The results of B/C evaluations were compared with the rough cost estimates of countermeasures in Part A of this Study.

#### ➤ **Restoration Level**

The difficulty of restoration was evaluated assuming a disaster maximum in scale.

The above-mentioned items were considered not only to establish a system of maintenance work required by MTI, but also to enhance the traffic efficiency of the road network and to assist with the development of local area economies.

The target year for the FS has been set at 2020 based on the NTP. According to the NTP, the reasons for selecting 2020 as the target year is to strategically advance the economic development of Nicaragua and establish appropriate functions for the future transportation system of Nicaragua.

### **15.2 Disaster Prevention Spots for the Feasibility Study**

Countermeasures taken up for consideration for the disaster prevention spots identified in Chapter 14 are as follows:

- i) Countermeasures for rocks falling or collapsing,
- ii) Countermeasures for rocks collapsing,
- iii) Countermeasures for slope sliding,
- iv) Countermeasures for debris flows, and
- v) Countermeasures for bridge foundation scouring.

Each of the above countermeasures deals with a different problem, such as weathered geology, seepage water, lava plateau characteristics, loose rocks, steep slope gradients, etc. The countermeasures proposed for each disaster prevention spot are as shown in Table 15.2.1.

**Table 15.2.1 Disaster Prevention Spots and Countermeasures  
for Feasibility Study**

| Priority | Objective Road | Serial No. of Critical Spots | Type of Disaster | Type of Countermeasures                   |                                   |

**CHAPTER 16**  
BASIC DESIGN STANDARD

## CHAPTER 16 DESIGN STANDARDS

### 16.1 General (Applicable Geometric Design Standards)

#### 16.1.1 Objective of Chapter

Applicable geometric standards for each disaster prevention spot are decided in this chapter using the results of the traffic volume survey carried out by the Study and cross-section width based on the geometric standards of Nicaragua (see Chapter 2).

#### 16.1.2 Results of Traffic Volume Survey

Traffic volume for both the present and future for the disaster prevention spots is as shown in Table 16.1.1. All spots are classified at present as Class A3 roads (i.e., rural trunk roads) using the geometric standards shown in Chapter 2. On the other hand, many of spots can be reclassified in the future as Class A2 roads (i.e., suburban trunk roads) owing to potential future increases in traffic volume.

On the other hand, the study has decided to carry out its design work on the assumption that these roads will remain as Class A3 road for the following reason;

- Other International Donor has done the same in their work.
- The main function of this study is road -related disaster prevention and not road improvement itself.

#### 16.1.3 Geometric Standards Applied

Based on the data contained in Table 16.1.1, the geometric standards adopted for this Study are as shown in Table 16.1.2. However, since the purpose of the Study is to prevent the occurrence of road-related disasters and not the improvement of roads, alignment improvements are only carried out when it is effective for preventing such disasters from happening.

Table 16.1.1 Results of Traffic Volume Survey

| No            | Traffic Volume  |      | Functional Classification |        | Type of Terrain | Design Speed | Recommended Road Width |            |           |

### 16.1.4 Distance to Roadside Obstacles & Stopping Sight Distance

There are a few spots where sight distance for a road is poor due to such things as slope overhang. In such cases, safety can be improved by eliminating the cause of poor sight distance, which is set based mainly on design speed. The required minimum distance to roadside obstacles for stopping sight distance for a horizontal curve can be calculated using the formula below and is as shown in Figure16.1.1.

#### Calculation Method of Distance to Roadside Obstacles

$$E = D^2/8Ra$$

E: Distance to Roadside Obstacle (m)

D: Sight Distance  $\cong$  S (m)

Ra: Radius (m)

Figure16.1.1 Relation of Sight Distance and Radius

## 16.2 Design Standards

### 16.2.1 Standards for Slope Gradients

#### 1) Embankment Gradient

In Nicaragua, embankment gradient is decided by traffic volume and embankment height. For example, a gentle slope is usually applied in the case of an embankment with a height of less than 1.2 m. The recommended standards for the gradients of embankment is shown in Table 16.2.1.

Table 16.2.1 Recommended Standards for Embankment Gradients by Road Type

| Functional Classification          |         | Minor Collector | Major Collector | Minor Arterial | Principal Arterial | Special Arterial |
|------------------------------------|---------|-----------------|-----------------|----------------|--------------------|------------------|
| Number of Lanes                    |         | 2               | 2               | 2              | 2                  | 4                |
| Future Average Daily Traffic (vpd) |         | 0-400           | 400-1,800       | 1,800-3,000    | > 3,000            | > 3,000          |
| Side-slope                         | On Fill | H < 1.2 m       | 3:1             | 3:1            | 4:1                | 4:1              |
|                                    |         | H > 1.2 m       | 1.5:1           | 1.5:1          | 2:1                | 2:1              |

#### 2) Cut Slope Gradient

The standards for the gradients of a cut slope in Nicaragua are decided by geological soundness and traffic volume (Table16.2.4). Geological soundness is classified into four types: sound rock, unknown soil, well-compacted soil, and poorly compacted soil. Note that it

is not necessary to have detailed geological data. Recommended standards for the gradients of cut slopes are shown in Table 16.2.3.

It is worth mentioning here that tuff and muddy rock may affect the stability of slopes in many cases. Rock stability is considered taking into account two factors: hardness and loosening rate. In Nicaragua, rocks are classified into hard and soft, with rocks being classified as the former (or "I") when unconfined compression strength is more than 100kg/cm<sup>2</sup> and the latter (or "II") when unconfined compression strength is under 100kg/cm<sup>2</sup>. Soil/sand is classified as III. As for the loosening rate, Rocks are classified into either A or B, with A being rocks that loose large. Below, both of the factors of hardness and loosening are combined to classify rocks (see Table 16.2.2).

Loosen quality B Rocks that loosen slowly case Table 17.3.4 for details.

**Table 16.2.2 Concept for Rock Classification**

| Rock Quality Classification<br>According to Hardness   |   | Hard |      | Soft |
|--|---|------|------|------|
|  |   | I ←  | → II | III  |
| Rock Quality Classification<br>According to Loose Rate | A | IA   | II A | III  |
|  | B | IB   | II B |      |

Large ↑  
 ↓ Small

3) Berm

The standard for berms for cut slopes is as shown in Figure 16.2.1, and has been adopted by MTI. However, the basis for the standard is not fully understood. In this Study, a width of 1.5 has been adopted for berms.

Figure 16.2.1 Beam Standard in Nicaragua

## 16.2.2 Structures

### 1) Estimation of Scouring Range

Scouring depth can be estimated based on the results of experiments conducted by the National Institute for Land and Infrastructure Management (formerly the Public Works Research Institute) of the Ministry of Land, Infrastructure, and Transport (see Figure 16.2.2). Note however that calculations in this table cover the range of  $h_o/D < 3.5$ .

( $h_o$ : Mean water depth during flooding,  $D$ : Width of pier)

The calculated value below is only a sample, and it therefore important to confirm the amount of scouring via on-site measurements.

Width of river:  $W = 31.6$  m

Width of pier:  $D = 1.1$  m

Velocity of high water level:  $V = 60.12$  m/s

Mean water depth in flood:  $h_o = 2.67$  m

Average grain diameter of riverbed materials:  $d_m = 3.0$ mm

$h_o/D = 2.43$

$Fr = (V/(W \cdot h_o)) / \sqrt{(g \cdot h_o)} = 0.14$

Ratio of depth and grain diameter

$h_o/d_m = 890$

X: Horizontal distance of the range of scouring

Z: Maximum depth of scouring

$\theta$ : Angle of repose

D: Width of pier

**Figure 16.2.2 Area of Scouring**

The value  $h_o/D$  can be obtained from  $Z/D$  using the relationship between  $h_o/d_m$  and  $Fr$  (Figure 16.2.3-Figure 16.2.6) as a parameter.

$Z/D = 0.8$

$Z = 0.96$  m

The relationship between the angle of repose  $\theta$  and average grain size is shown in Figure 16.2.7.

Angle of repose  $\theta = 32^\circ$

$\tan \theta = 0.62$

$X = Z/\tan \theta = 1.54$  m

Figure 16.2.3 Assumption for Scouring Depth ( $h_o/D = 0.5-0.7$ )

Figure 16.2.4 Assumption for Scouring Depth (ho/D = 0.75-1.25)

Figure 16.2.5 Assumption for Scouring Depth ( $h_o/D = 1.75 \sim 2.25$ )

Figure 16.2.6 Assumption for Scouring Depth ( $h_o/D = 2.75 \sim 3.5$ )

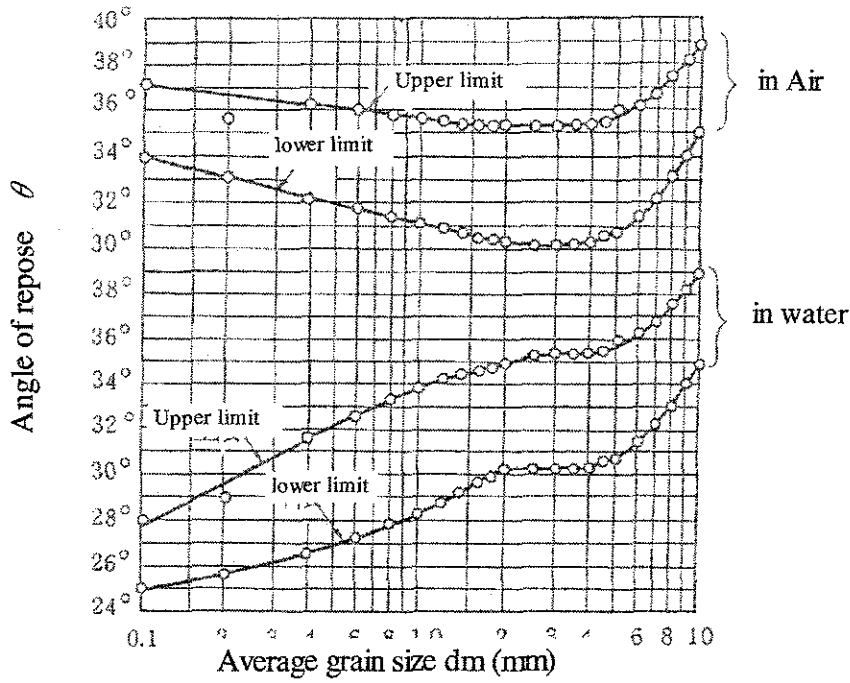

Figure 16.2.7 Relationship between Average Grain Size and Angle of Repose

2) **Relation between Size and Flow Velocity of Rubble-mound and Block**

Rubble-mounds and concrete blocks are placed around pier to prevent scouring. The size and shape of the concrete block are decided by the velocity of river. See Figure 16.2.8 and Table 16.2.5.

Figure 16.2.8 Relationship between Size of Debris and Velocity of Water Flow

Table 16.2.5 Relationship between Weight of Blocks and Velocity of Water Flow

| Shape     | Weight of Block (ton) | Velocity of Water Flow (m/s) |
|-----------|-----------------------|------------------------------|
| Flat type | 1.0                   | 2.5                          |
|           | 2.0                   | 3.0                          |
|           | 3.0                   | 3.5                          |
|           | 4.0                   | 4.0                          |
|           | 5.0                   | 4.5                          |
|           | 6.0                   | 5.0                          |

### 16.3 Standard Typical Cross-section and Right-of-Way

#### 16.3.1 Confirmation of Standard Value

As stated in Section 16-1, all disaster prevention spots are Class A3 roads (i.e., rural trunk roads). The typical cross-section and right-of-way of Class A3 roads are as shown in Table 16.3.1.

**Table 16.3.1 The typical cross-section and right-of-way of Class A3 roads**

| No.    | Description Item      |                            | Trunk Road                     |                                |
|--------|-----------------------|----------------------------|--------------------------------|--------------------------------|
|        |                       |                            | Suburban                       | Rural                          |
| 1      | Number of Lanes       |                            | 2 to 4                         | 2 to 4                         |
| 2      | Lane Width (m)        |                            | 3.30 - 3.65                    | 3.30 - 3.65                    |
| 3      | Shoulder Width (m)    |                            | Int: 1.0 - 1.5, Ext: 1.5 - 1.8 | Int: 0.5 - 1.0, Ext: 1.0 - 1.8 |
| 4      | Road Right-of-Way (m) | Recommended Value          | 40 - 50                        | 40 - 50                        |
|        | Road Site Law (1952)  | Nic 1                      | 40 (international road)        |                                |
|        |                       | Nic 3                      | 20 (interstate trunk road)     |                                |
|        |                       | Nic 5                      | 20 (interstate trunk road)     |                                |
| Nic 26 |                       | 20 (interstate trunk road) |                                |                                |

Note: Int means inside curve; Ext means outside curve

As for the width of a shoulder on the inside of a curve (Int), since all the disaster prevention points are located on 2-lane, it is not taken into consideration. As for right-of-way, it is suitable to follow the existing law.

#### 16.3.2 Standard Typical Cross Section

The typical cross-section for the Study roads in consideration of the above standard values is as shown in Figure 16.3.1.

**Figure 16.3.1 Standard Typical Cross-section and Right-of-way**

### 16.3.3 Confirmation of Existing Road Width

The results of checking the existing road width of the disaster prevention spots are as shown in Table 16.3.2.

Table 16.3.2 Status of Existing Road Width

| No            | Existing Width  |             |                 |             | Necessary Min. Width |       | Judge |    |

| 30            | Solis           | -           | 7.31            | -           | 7.31                 | 6.6   | 9.0   | OK |

Because existing road shoulder width can not be confirmed, the width check of the Table 16.3.2 shows the result of the comparison by the existing paved width and the standard carriageway width. Standard value is satisfied as a carriageway width as shown in the table at the almost all points. However, as for two places of NIC.3, standard value isn't satisfied.

**CHAPTER 17**  
CLOSE EXAMINATION OF  
COUNTERMEASURES

## CHAPTER 17 DETAILED EXAMINATION OF COUNTERMEASURES

### 17.1 General

The objectives of this chapter are to confirm the status of disaster prevention spots and examine in detail possible countermeasures. First, the results of Phase 1 of the Study shall be re-examined by considering the effects of the rainy season in Phase 2, and then necessary modifications made if any unstable factors are observed. Second, various kinds of analyses on slope stability and bridge foundation scouring shall be performed. Third, and finally, appropriate countermeasures shall be proposed.

### 17.2 Confirmation of the Status of Disaster Prevention Spots

#### 17.2.1 Consideration of Slope Surface Factors in Countermeasures

In brief, slope surface conditions in rainy and dry seasons differ in wet condition variations on the surfaces, changes associated with them and vegetation thickness.

Based on the Phase 2 study, it was found that slope surface wet conditions contained surface water, spring water with some hydraulic gradient and water film oozing. These wet conditions affect principally weathered layers consisting of a tuff group. It is observed that the wet conditions induce new fall of rocks due to repeated dry and wet conditions, reduce bearing capacity due to hair crack-based spalling promotion or collapse due to increasing pore water pressure. This weathering process of the tuff group shifts much-cracked andesite rocks overlaid to overhanging blocks or generates toppling, which will soon lead to falling of the andesite rocks. The andesite rocks develop in mainly 4-5 m-thickness layers and also many auto-breccia rocks (when the rocks began hardening from lava, they were broken into small rock fragments because of being pushed away by continuous lava flow. Therefore, they are filled with the same rocks as crashed rock fragments.), occurring in brecciated condition on the slope surface. In addition, since the andesite rocks were originally produced by lava flow, they include vertical cooling joints (generates shrinkage cracks generated from lava cooling), the development of their weathering provides a causative factor to cause rock fall.

In the Phase 2 study, we reviewed the Stability Investigation Table of the Phase 1 study and then continued the site survey in accordance with the following flow chart (Figure 17.2.1) to consider countermeasures against slope surfaces stability meeting the need of construction sites, with the intention of identifying the process of water flow in rainy season on each slope surface and the relation between the flow and the surface stability.

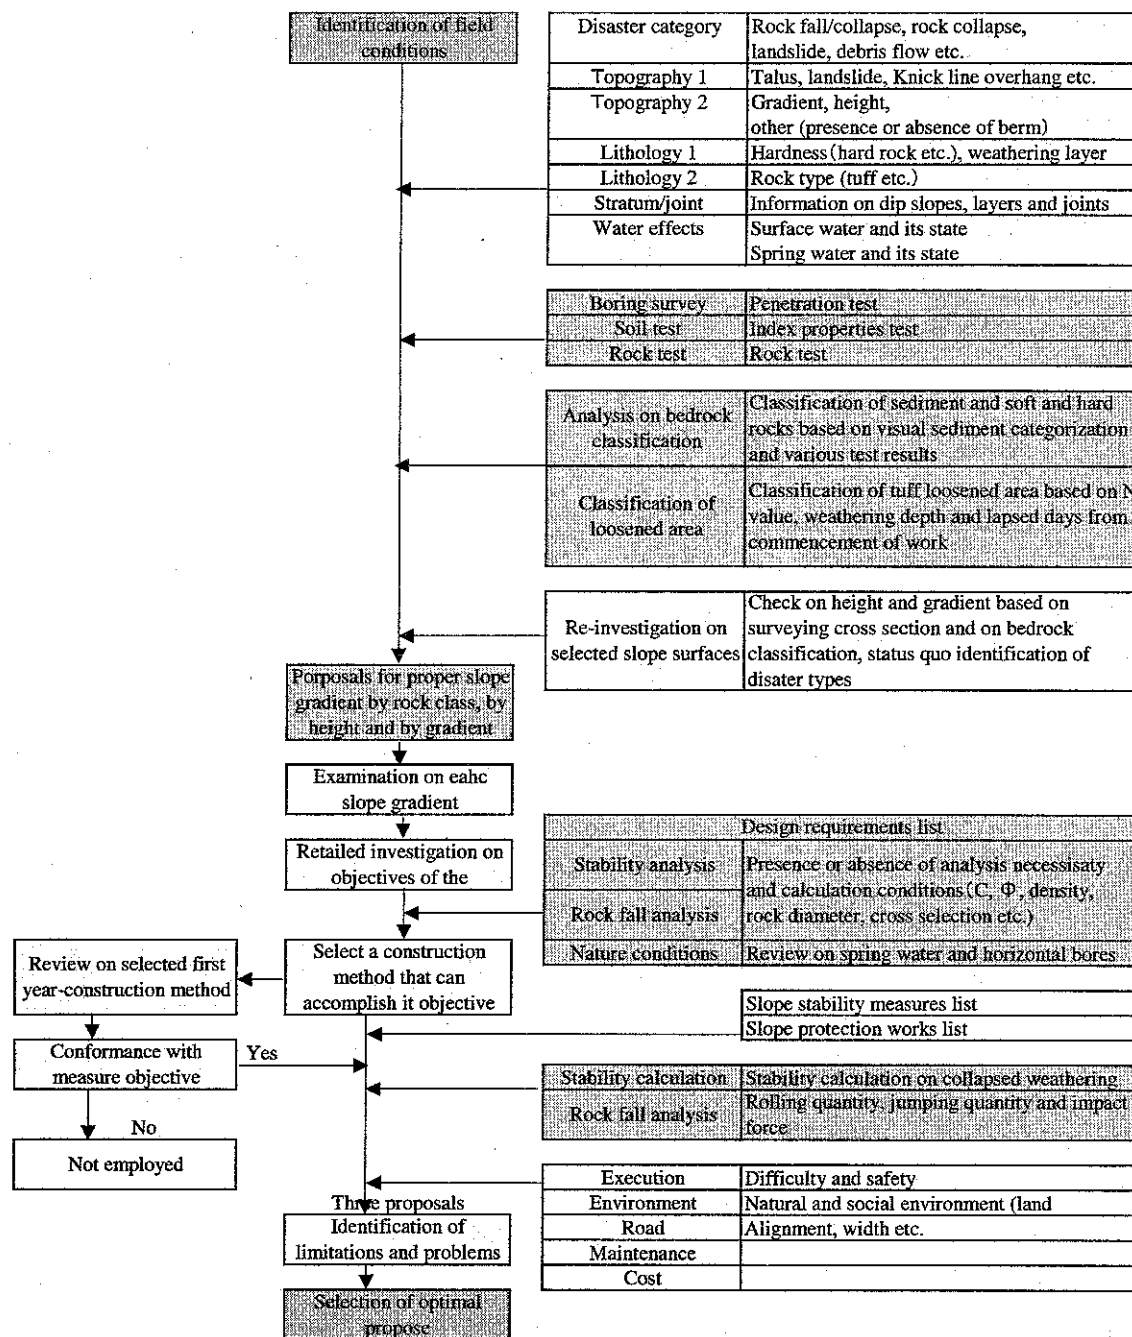

Figure 17.2.1 Selection Flow of Counter Measures against Slope Surface

Next, the Phase 2 study shows how evaluation in Phase 1 study has been changed after identifying the effects of mainly rainfall.

Review results of the Stability Investigation based the Phase 2 study is shown in Table 17.2.1. A bold letter in Table 17.2.1 shows the evaluating point that was changed by the Phase 2 study.

**Table 17.2.1 Review Results List of the Stability Investigation based on the Phase 2 Study**

15 points in boldface of 19 points in Table 7.2.1, picked up by this survey represent rainfall-affected slope surfaces. Next, key points of this investigation and its results are described.

**1) Secondary Survey Notes**

As mentioned above, since it can be considered that the bedrock in a surveyed area was affected by weathering force in the process of long-term geological time, the bedrocks on the slope surfaces lie in a certain weathering zone more or less. Weathering events include short-term weathering such as slaking and swelling. However, it might be justified that this weathering in the process of long-term geological time caused slope stability within “a loosened area of the bedrock.” Based on this current state and the results of this survey, priority is given to the following points for disaster prevention.

- i) Removal of unstable or potential unstable loose blocks or rolling stones
- ii) Flattening the existing bedrock slope
- iii) Removal of overburden load from the bedrock slope head which may fail in future (These countermeasures include mainly re-cutting of the slope.)
- iv) Establishment of berms on the bedrock slope
- v) Water Draining by horizontal bore holes and interceptors

**a) Removal of Unstable or Potential Unstable Blocks or Rolling Stones**

Some of the cut slopes surfaces require their forming for disaster prevention and maintenance due to that rock fall and collapse are repeated and that there are loose, overhanging or protruding blocks. Before forming the slopes, it should be noted which block on each slope to be removed, however, this survey focused on andesite rocks containing opening cracks, slopes subject to the risk of overhanging and toppling collapse and tuff with a wide loosened part.

In particular, the originally cracked andesite rocks form a causative factor inducing rock fall after weathering enlarges their apertures. Falling area, width and depth used for the Ritchie (1998)'s design of rock fall prevention works modicate more information since they are related to the design of rolling and jumping quantity of falling stones analyzed by this survey.

Symbols in the following table shall be based on the following figure.

**Figure 17.2.2 Rock Fall Locus Model**

**Table 17.2.2 Ritchie's Design Case for Rock Fall Protection Works and This Survey-Based Rock Fall Analysis Calculation**

|               |  | >30              | 1.7                      | 3.9                  | 7.6                   | 2.7'                 |
|               | 50   | 0-10             | 0.4                      | 0.0                  | 3.7                   | 1.0                  |
|               |  | 10-20            | 0.7                      | 1.0                  | 4.6                   | 1.2                  |
|               |  | >20              | 0.8                      | 1.3                  | 4.6                   | 1.8'                 |
|               | 40   | 0-10             | 0.3                      | 0.0                  | 3.7                   | 1.0                  |
|               |  | 10-20            | 0.3                      | 0.0                  | 3.7                   | 1.5'                 |
| >20           |  | 0.7              | 0.5                      | 4.6                  | 1.8'                  |                      |

(°): In case of using prevention fences, 1.2m shall be applied.  
 In this calculation case, a block diameter shall be 1m.

According to Ritchie's design case, free fall shall be about 4 D compared with 1D of rolling.

The above two cases cannot be simply compared, but it might be said that Ritchie was conservative in setting countermeasures of groove width against rolling quantity.

#### b) Flattening the Existing Bedrock Slope

The cut standard in Nicaragua will be described in a later section. The key points are summarized in the following table (Table 17.2.3).

**Table 17.2.3 Cut Slope Standard in Nicaragua**

| Nicaragua's standard on cut slope |                         |  |  |
|-----------------------------------|-------------------------|--|--|
|                                   | Rock Facies             | Trunk road                               | Feeder road                              |
| Cut                               | On Sound Rock           | 0~1/2 : 1<br>(90° ~ 63°)<br>[0 : 1(90°)] | 0~1/2 : 1<br>(90° ~ 63°)<br>[0 : 1(90°)] |
|                                   | Well Compacted Soil     | 1 1/2~2 : 1<br>(34° ~ 26°)               | 1~1 1/2 : 1<br>(45° ~ 34°)               |
|                                   | Unkown Soil             | 1~1 1/2 : 1<br>(45° ~ 34°)               | [1 : 1 (45°)]                            |
|                                   | Not Well Compacted Soil | 2 : 1(26°)<br>[1 1/2 : 1(34°)]           | 1 1/2 : 1(34°)<br>[1 : 1 (45°)]          |

The cut slope gradient for bedrocks is left to the judgment of field engineers within the range of 63~90°. In fact, NIC.00 uses 0.75 × 1 (about 55°) for many cracks-bearing bedrocks and 0.5 × 1 (about 63°) for solid tuff. However, considering field conditions, the following features are identified.

- Individual slope cannot be equally treated due to that andesite rock and tuff layers exist alternately or separately.
- Some tuff, which has fast weathering characteristics, contributes to overhanging and toppling collapse of andesite overlaid or insufficient strength in a loosened area of tuff causes some small-scale landslides. For these reasons, tuff needs to be classified.
- Some cuts have a slope height of 30 m or more. They have continuous rock fall and collapses and are not always stable even if they meet the Nicaragua's standard.
- Some stratum such as granite-weathered sediment and unconsolidated soils Diluvial talus cannot be treated as Alluvial deposit.

In consideration of these features, each proper gradient was examined based on the existing slope height, gradient and its bedrock category. The results will be described in the next section.

#### c) Removal of Overburden Load from the Bedrock Slope Head

**which may Fail in Future (These Measures Include Mainly Re-Cut of the Slope)**

There are distinctive landslides and collapses such as weathered tuff slope landslides in NIC.1 and NIC.3, slope destabilization by cutting the foot of ex-taluses in NIC.5 and collapse of a fractured zone in NIC.26 tuff. Stability analysis showed that removal of soil would

significantly improve a safety factor. So, measures for the maximum reduction of overburden load on the slope were reviewed, and it was determined that loading berm could prevent collapse of embankment. Since the two methods of soil removal and loading berm cannot completely support current draining, particular attention should be paid to slope drainage.

#### d) Establishment of Berms on the Bedrock Slope

Frequent spalling and small-scale collapse are found on tuff slopes in the area due to repetition of dry and wet conditions while tuff and andesite rock falling occurs frequently. The minimization of rock fall to roads can be made by establishing berms. This countermeasure is set as guidelines in Nicaragua, but berms can be established at intervals of 4 to 8 m according to field conditions. Alternate existence of many cracks-bearing andesite rocks and faster-weathering tuff layers was often found in this surveyed area. During a rainy season, water often exuded mainly from a boundary between the two layers in various ways. Assuming berm drainage, it is recommended that berms should be established near a boundary between strata with much spring water, but a berm surface is actually placed at a lower part of relatively a softer layer or at an impervious layer due to slanted strata.

#### e) Water Draining by Horizontal Bore Holes and Interceptors

In this survey, establishment of horizontal drain holes was reviewed with the intention of draining surface water and lowering a ground water level when re-cutting slope surfaces in landslide lands. It was determined that iron oxide-adhered and open cracks-bearing tuff bedrocks would be drilled to construct the holes. The bedrocks in NIC.3 and NIC.5 can be expected to have good drainage. Therefore, it is proposed that 4 to 5 horizontal drain bore holes should be established in a parallel with their length of 15 to 20 m (almost half of slope height of these bedrocks) in order to drain water in bedrocks behind landslide surfaces.

(Plan)

(Cross-section)

Figure 17.2.3 Horizontal Boring Drainage

## 2) Difference between the Conditions of Individual Slope Surfaces during Dry and Rainy Seasons and Measures against Slope Surfaces

Based on the above-mentioned reviews, the difference between the conditions of individual slope surfaces during dry and rainy seasons is summarized in the following table. Descriptions illustrated with photographs will be provided in a section of a design for measures against slope surfaces. Here, it is briefly shown in Table 17.2.4.

**Table 17.2.4 (1) Difference between the Conditions of Individual Slope Surfaces during Dry and Rainy Seasons and Countermeasures against Slope Surfaces for NIC.1**

| ID (km)               | Spring Point  | Rock-fall and Collapsing   | Review on Countermeasures against Slope Failure  |
|-----------------------|---|--|--|
| N001A290<br>(60.9km)  | A little water exudes near a boundary between the remaining taluses and from loosened cracks.   | Falling of 10 to 50 cm-small blocks are often seen. The blocks do not hit the road due to its wide margin, but slope collapse may affect the up lane due to loose of the slope.  | It is recommended that berms should be established in order to reduce rock fall impacts, but the measures reviewed are removal of loosened blocks and rolling stones, drainage of slope shoulders and toes and establishment of net works since the road has a large margin. |
| N001A280<br>(73.2km)  | 8 continuous spring points are seen during dry and rainy seasons. Further water exudes from colluvial deposits during the rainy season  | A some 2 m-slide scarp can be clearly seen. The slide movement is currently at rest on the scarp, but there is a danger of sliding when heavy rain causes increase of the water level. Collapse of the scarp may totally block the road.                 | Colluvial deposits need be stabilized due to their potential movement after heavy rain.  |
| N001A240<br>(168.4km) | Surface water exudes in a sheet shape from a boundary between andesite and tuff through andesite cracks. In this survey, spring points cannot particularly be observed.                   | Since a small overhang ridge was cut, a weathering layer of tuff remained across the slope. Rock fall will offer low visibility for the road. So, cars on the down lane will be exposed to diaster dangers. Small collapses are found at 10 points.      | Grasses and small- and medium-size tress grown on the slope surface are effective in slope stabilization and rock fall prevention. The proposals for removal of loosened blocks and rolling stones and placement of partial nets at the denuded land were reviewed.          |
| N001B230<br>(168.6km) | This slope is connected with the above slope. Its bedrock has more blocks than that of the above slope. A little water 175.0exudes near a boundary between andes 176.2ite and tuff rocks. | The bedrock is weathered to soil near a boundary between andesite and tuff rocks where small-scale collapse and rock fall continue. There are andesite rocks on a height at a blind corner. A 50 cm or more-diameter rock may hit cars on the down lane. | As the above slope, it has higher weathering depth, while grasses and small- and medium-size tress were re-grown. So, the proposals for removal of loosened blocks and rolling stones and placement of partial nets were reviewed.   |

| ID (km)               | Spring Point   | Rock-fall and Collapsing  | Review on Countermeasures against Slope Failure   |
|-----------------------|--|---|---|
| N001B170<br>(171.3km) | There are two points where storm water through andesite cracks exudes from the cracks and a boundary between andesite and tuff rocks.            | The tuff is originally resistant to weathering, but it is located at the end of a small ridge where a weathering layer remains and andesite rocks fall. Low visibility for the down lane will cause disaster dangers. | It is located at the end of a small ridge where a weathering layer remains and severe tuff spalling is observed. In addition, opening cracks in andesite rocks are further expanded, while toppling collapse or falling from higher points can be seen. There are blind corners. Only removal of loosened blocks cannot contribute to fundamental improvement. So, a proposal for re-cut. |
| N001B150<br>(175.0km) | Surface water exudes and water springs from vertical cracks of andesite rocks and lower tuff.  | Tuff containing cooling joints repeated its spalling, providing toppling collapse and falling. Cars on the up lane will be exposed to disaster dangers.   | A 1 m or more-diameter block sometimes falls to the down lane from a crack space. So, a proposal for re-cut of upright sections and sparring works was reviewed.  |
| N001B120<br>(176.2km) | It is located at the ridge end overhanging on the river and normally has no spring water. Two spring points were observed during a rainy season. | The bedrock is not in good state due to fault involvement. But, dyke rocks along fault are harder. Repeated and full collapses will make the road completely impracticable. There are no bypass roads near here.      | Sharp cut gradient is taken due to worse bedrock and steeper topography. There are past collapse records and no bypass roads. So, a proposal for 55° re-cut.  |

**Table 17.2.4 (2) Difference between the Conditions of Individual Slope Surfaces during Dry and Rainy Seasons and Countermeasures against Slope Surfaces for NIC.3**

| ID (km)             | Spring Point  | Rock-fall and Collapsing  | Review on Countermeasures against Slope Failure  |
|---------------------|---|---|--|
| N003B400<br>(6.9km) | Water penetrates along cooling joints, and there are two points where water springs from a boundary between layers. | Lower welded tuff at the foot became grained, repeated toppling collapse near a boundary between the two layers. The fluidization of tuff at heavy rain will block the road.                  | A proposal for cutting an upright section in toppling collapse at the angle of 60° was reviewed. |
| N003B370<br>(7.4km) | It has the same stratum, but no particular spring water. It has collapse records at heavy rain.                     | Lower welded tuff at the foot became grained, repeated toppling near a boundary between the two layers. The tuff fluidization at heavy rain will block the road. This may affect the up lane. | A proposal for cutting an upright section in toppling collapse at the angle of 60° was reviewed. |

| ID (km)              | Spring Point  | Rock-fall and Collapsing  | Review on Countermeasures against Slope Failure  |
|----------------------|---|---|--|
| N003B320<br>(22.1km) | There is a hotel. Flow of miscellaneous waste water and surface water is concerned. There are two spring points on the slope surface.       | It is located at the end of a small ridge where tuff became soil. It is impossible to cut the slope due to influence on the hotel.  | A weathered layer of tuff belongs to Bedrock Category III. So, it is determined that slopes with gradients at 45° or less will be stabilized. But, in the case of these gradients, since the slope cut will affect the hotel, a proposal for establishing some structure was reviewed. |
| N003C230<br>(32.9km) | There are flows of surface water and groundwater. Some of groundwater springs at two point of embankments.                                  | There is a slide scarp on the slope surface which may fluctuate at heavy rain. If water penetrates embankment cracks, the slope will collapse, which may affect traffic.  | Since it belongs to Bedrock Category III, it needed be re-cut at the angle of 45~55°   |
| N003E170<br>(35.2km) | There is no spring water. But, Hurricane Mitch caused flash flooding and water spurts on the hillside.                                      | Generally, tuff and andesite rocks are thermally deformed, with their rapidly hardening and softening variations. Spalling, rock fall and piping-based shallow collapse are seen on the slope, which are likely to result in hazard to moving traffic on the up and down lanes. | It is located at a alteration zone of tuff and andesite rocks, with their rapidly hardening and softening variations. So, it was proposed to re-cut the slope at the angle of 55° A proposal for constructing a simple dam in a small valley was reviewed.                             |
| N003C150<br>(38.9km) | Surface running water at ordinary rain, water springs on a middle part of embankment there are waterways on bedrock at heavy rain are seen. | Thermally deformed tuff was weathered on the cut with some tuff slide. The tuff may fluidize at heavy rain, which affects the up and down lanes.  | It is a weathered layer of thermally deformed tuff and belongs to Bedrock Category III. A proposal to re-cut it at the angle of 45°.   |
| N003C140<br>(39.4km) | There are no distinctive water spring and seepage. The bedrock contains many cracks and becomes red with iron oxide.                        | Thermally deformed tuff was weathered on the cut side with some tuff slid. The tuff may fluidize at heavy rain, which affects the up and down lanes.  | It has the same measures as the above. Waterways were confirmed in bedrocks. So, horizontal drainage works were reviewed.  |

**Table 17.2.4 (3) Difference between the Conditions of Individual Slope Surfaces during Dry and Rainy Seasons and Countermeasures against Slope Surfaces for NIC.5**

| ID (km)              | Spring Point   | Rock-fall and Collapsing   | Review on Countermeasures against Slope Failure   |
|----------------------|--|--|---|
| N005A010<br>(24.5km) | 8 spring points and seepage from entire talus layers were confirmed. But dry season was a little water quantity. | Continuous small collapses and rock fall occur on a talus whose condition keeps unstable. The continuous collapses cause hazard to moving traffic. The talus may fully collapse. | Due to that the foot of Diluvial taluses was cut, some remaining on the slope became instable. It belongs to Bedrock Category III. The current slope gradient is 41° to 48° and instable. So, a proposal for 40~ 35° slope stabilization, |

**Table 17.2.4 (4) Difference between the Conditions of Individual Slope Surfaces during Dry and Rainy Seasons and Countermeasures against Slope Surfaces for NIC.26**

| ID (km)              | Spring Point  | Rock-fall and Collapsing   | Review on Countermeasures against Slope Failure   |
|----------------------|---|--|---|
| N026A060<br>(24.7km) | There are spring points. In general, there are many seepage points from cracks (8 points).                          | Bedrocks generally consist of I B hard rocks. But spalling and small collapses on their weathering layers and falling of blocked tuff are observed. Currently, traffic moving is ensured by removal of stones.   | There are no problems about slope stability. So, a proposal for slope surface forming and spraying works was reviewed.  |
| N026B140<br>(34.0km) | There are two spring points around the shuttered zone.  | There is an about 50 m-width fractured zone where rock fall and collapse always are repeated. The bedrocks in the fractured zone belong to Bedrock Category III, where rock fall from a slide scarp and collapses frequently occur, being hazard to traffic moving all through the year. In addition, the bedrocks around the fractured zone are unstable, with a lot of spalling and rock fall. | This is an area where volcanic rocks around the fractured zone contain black schist and there were a big crustal movement. The depth of the crush zone is affected by weathering. Rock fall and collapses always continue on the zone. So, a proposal for 40°re-cut,. |
| N026A150<br>(34.2km) | Currently, water seepage is observed. There were concentrated surface running water and springs at Hurricane Mitch. | This is an area with agglomerates where igneous activities are generated. Rock fall and collapses frequently occur on the whole slope due to the existence of a 20 m-drop fault and its overall alteration. There were a great collapse at Hurricane Mitch. Collapsed soils are always removed.  | The bedrocks around the slope toe belong to Bedrock Category I B, but the bedrocks on the slope were weathering. So, a proposal for 55°slope re-cut.  |
| N026B160<br>(37.0km) | Two spring points were observed under this survey.  | There are some areas where expansion of andesite cracks causes toppling collapse. Potential large block fall will hit people and cars.   | A proposal for removal of loosened blocks and rolling stones and full net works was reviewed.   |

### 17.2.2 Consideration of Countermeasures for Scouring

Of the 30 disaster prevention spots selected, 11 are bridges and are as shown in Figure 17.2.4. The present condition of each bridge is described in Table 17.2.5. In addition, a summary of the survey results for each bridge is given in Appendix B1.
