3. REVIEW OF DEMAND FORECAST

The demand forecast was reviewed as shown in the following flow chart, based on the public traffic OD matrix of KTIP. The demand forecast of KCR was conducted by the same method, Transit Assignment, as SAPROF-I.

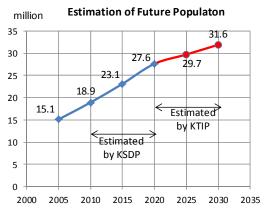

Source: JICA Study Team

Figure 3.1.1 Flow of Demand Forecast

3.1 Socio-Economic Framework and Urban Planning

3.1.1 Future Population

Population of Karachi City until 2020 was estimated in KSDP2020. The Average Annual Growth Rate (AAGR) after 2005 decreases by 0.5% every five years. On the basis of prediction of KSDP2020, in 2020 and afterwards, KTIP assumed that a pace of expansion became slow, and estimated the population in 2030 to be 31.6 million people.

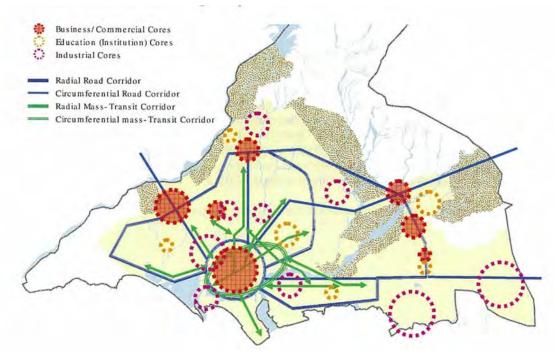

Source: KTIP

Figure 3.1.1 Estimation of Future Population

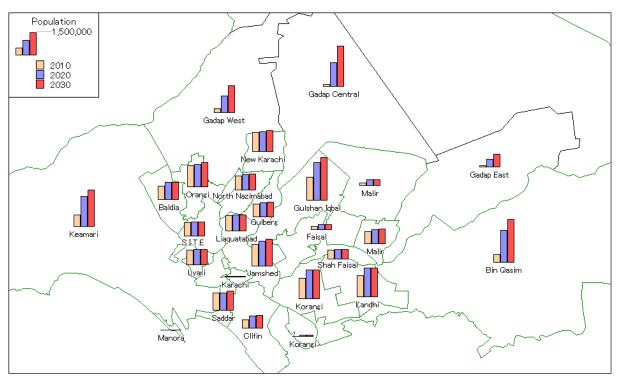

3.1.2 Urban Planning

In 2010, the population density of the urban area in Karachi is 238 persons/ha, and it is a quite high level even compared in the world. KTIP assumed that it became a level of 200 persons/ha in the whole Karachi city, and formulated the land use plan corresponding to 12.7 million increase in population predicted in 2030. In this case, it is assumed that urban area is expanded from 79,567 ha to 158,000 ha in 2030. KTIP follows the plan of KSDP2020 considered as a plan to arrange a city base in the suburban part. As the result, the increases in the population by 2030 will be 4.5 million people in Gadap Town of northern part, 2.1 million people in Bin Qasim Town of eastern part and 1.5 million people in Keamari Town of western part.

Source: KTIP

Figure 3.1.4 Future Population growth by Town/Cantonment (2010, 2020, 2030)

3.2 Traffic Analysis Zones

The traffic analysis zones for demand forecast was set into 216 zones of KTIP more finely divided from 151 zones of SAPROF-I. The range of access by walk from a KCR station was supposed to be within a radius of 1 km of the station. The traffic analysis zones in KTIP and SAPROF-I which include such accessible ranges are shown in Figure 3.2.1 and Figure 3.2.2 respectively.

The Cantonment area was subdivided more, and the boundary is scrutinized and changed also in the zone of Town. As a result, as compared with SAPROF-I, the area of the zone corresponding to a KCR sphere of train station decreased for a while.

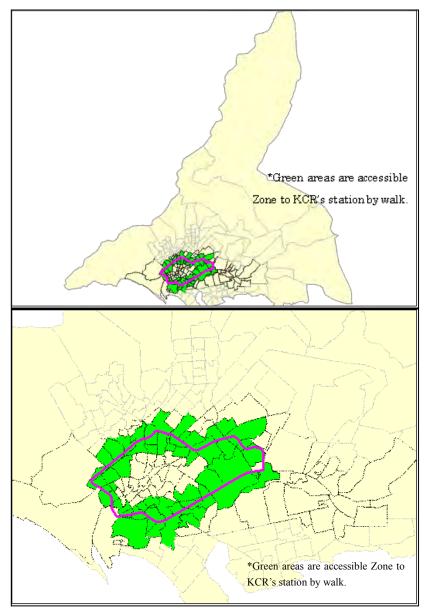

Figure 3.2.1 Traffic Analysis Zone of KTIP

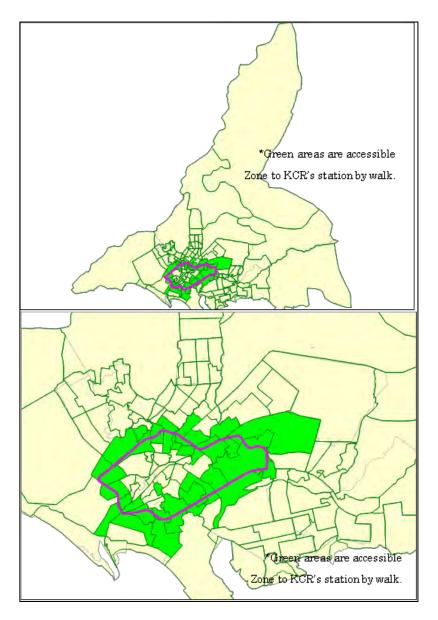

Figure 3.2.2 Traffic Analysis Zone of SAPROF-I

3.3 OD Data for Public Transport

The used OD matrix of KTIP is estimated with full network case that includes all future highway projects and mass transit.

The total transport volume from KTIP has 18.3 million trips per day in year 2020. This indicates 45% lower than the predicted volume in SAPROF-I, that is 33.8 million trips per day in year 2023. The public transport volume from KTIP is 9.3 million trips per day in year 2020, which is 32% lower than the predicted volume of SAPROF-I, that is 13.9 million trips in year 2023.

Table 3.3.1 shows the number of trips by mode forecasted in SAPROF-I and KTIP.

Table 3.3.1 Number of Trips and Modal Share by Mode

	Year	Motorcycle	Passenger car	Public	Truck	Total
SAPROF-I	2023	9,813,424	10,057,563	13,878,226	12,822	33,762,035
		29%	30%	41%	0%	100%
KTIP	2020	2,929,114	5,963,006	9,353,627	47,938	18,293,685
		16%	33%	51%	0%	100%
KTIP	2022	3,008,249	6,122,130	9,757,767	50,222	18,938,368
		16%	32%	52%	0%	100%
KTIP	2030	3,325,528	6,758,517	11,376,018	59,544	21,519,607
		15%	31%	53%	0%	100%

The public transport generation/attraction trips by zones in KTIP and SAPROF-I are shown in Figure 3.3.1 and Figure 3.3.2 respectively. The public transport trips of central parts decreases in volume as compared with SAPROF-I. On the other hand, in the suburban areas forecasted public transport demand is fairly large in KTIP, and traffic distribution pattern differs greatly.

The number of trips at the beginning of operation 2022 year was divided proportionally and estimated based on the data in 2030 and 2020.

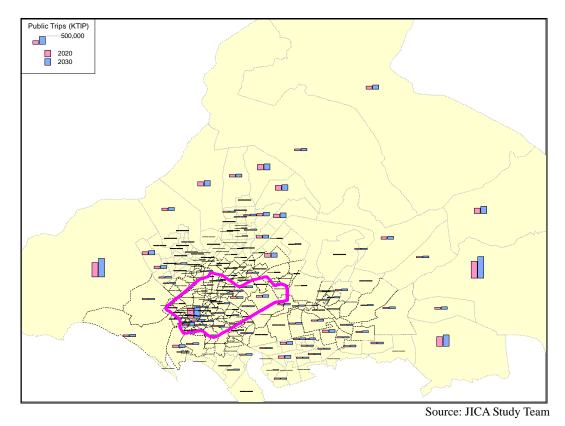

Figure 3.3.1 Public Trips by Zone (Year 2020/2030 KTIP)

JICA 3-6 NK-YEC-JEC

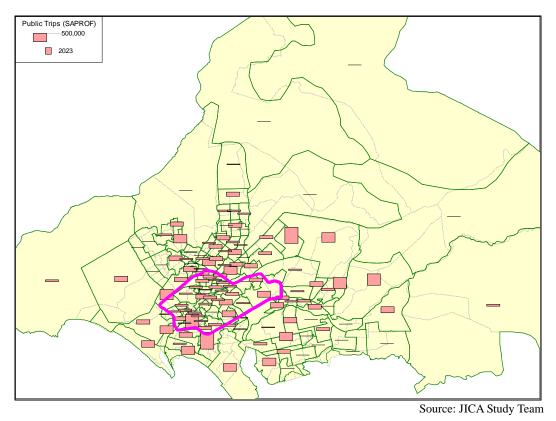

Figure 3.3.2 Public Trips by Zone (Year 2023 SAPROF-I)

3.4 Conditions of Demand Forecasting

3.4.1 Mass Transit Development Program

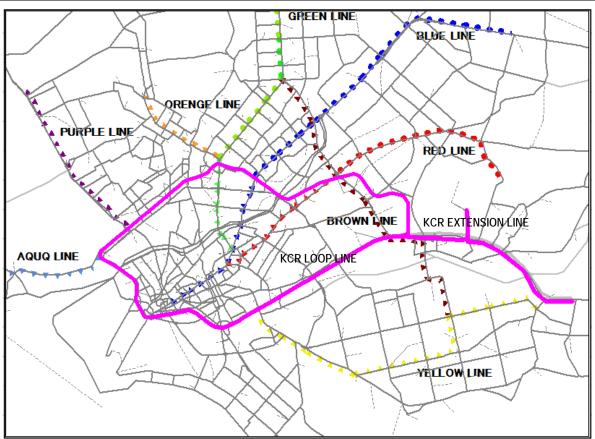

KCR development programs were assumed as two cases, while mass transit development programs were based on KTIP as shown in Table 3.4.1 and Figure 3.4.1.

Usually, since bus routes are what change in connection with urban structure or the traffic condition, the present bus routes shall be extended with development of the suburban area. Moreover, if KCR comes to operate, it is possible that the new feeder bus routes to the station are also improved.

Then, the conditions of the network of bus routes were assumed about the case which the present bus one extended to the suburban area, and the case where the feeder bus routes from KCR stations are fixed in addition. The assumed feeder network of bus routes are as shown in Figure 3.4.1.

Table 3.4.1 KCR Development Cases

Ro	Road Projects under construction		Projects of Master Plan	Projects of Master Plan					

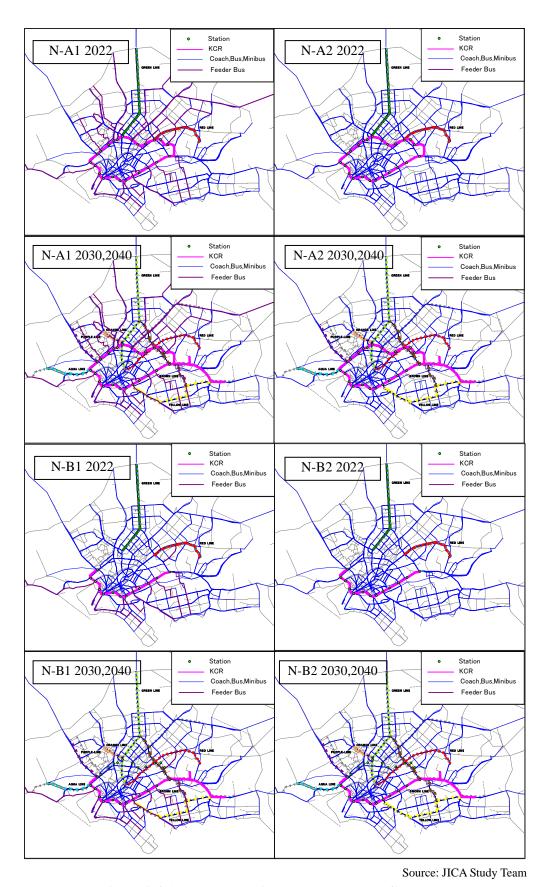

Figure 3.4.1 Mass Transit Network by Each Cases

3.4.2 Level of Service by Public Transport

The service levels of public transport modes were set as shown in Table 3.4.2.

The fare of KCR made small the difference with the present public transport modes for promotion of utilization at the beginning of operation. Then, after the user was established, it was considered as the strategy which raises a few. The time of the charge price increase was assumed to be 2030 when extension of KCR is improved.

3.4.3 Transfer Mode between KCR and Other Public Transportation

The transfer from KCR stations to bus stops are on foot. Usually, a railroad station and a station square are improved simultaneously and the transfer which is between a railroad and a bus becomes easy. However, since the lack of place for the station square, there are some KCR stations which cannot improve the station one.

This demand estimating of KCR is selected at a shortest path and its course up to 1.2 times based on the generalization travel cost in consideration of boarding time, waiting time, transfer time and its charge. At this time, it is selected at the path whose number of transfer times is up to 2 times as a realistic path.

Since transfer resistance was large when transfer distance is 240 m (3 minutes) or more, walking was considered one of traffic mode, and it counted to the number of transfer times. When transfer distance is less than 240 m, walking is not considered to be traffic mode and it does not count to the number of transfer times.

3.5 KCR Demand

The result of demand forecast for the KCR is summarized in Table 3.5.1. Passengers loading is presented in Figure 3.5.1 and Figure 3.5.2. Boarding and alighting passengers at each station are shown in Table 3.5.3, Table 3.5.4, Table 3.5.5 and Table 3.5.6. The estimated KCR demand for each year is shown in Table 3.5.7.

In case N-A1, the total numbers of passenger are estimated as 578,362 persons per day in 2022 and 1,223,066 persons per day in 2030. In case N-A2 the total number of passenger is estimated as 526,738 persons per day in 2022 and 1,174,107 persons per day in 2030. The difference of this amount demanded is the difference in whether the feeder buses to stations are improved, and its influence is about 10% for the demand of 2022 and 4% for that of 2030 respectively.

In case N-B1, the total numbers of passenger are estimated as 306,236 persons per day in 2022 and 828,018 persons per day in 2030. The numbers of passenger of the case N-B1 constitutes 53% of one of the case N-A1 in 2022 and 68% in 2030.

230,983

798,716

427,397

206,638 220,759

In case N-A1, the maximum section numbers of passengers are 236,999 persons between Karachi Cantt and Naval in 2022 and 448,476 persons in 2030. In case N-B1, the maximum section numbers of passengers are 225,101 persons in 2022 and 449,858 persons in 2030 at the same section. That is, even if KCR is loop route and it is the south route, there is no difference with the maximum section numbers of passengers.

The demand in 2040 is analyzed taking into account the increased travel speed of BRT inside the KCR to 25 km/h while the OD table remains unchanged from that in 2030.

In the case N-A1,A2 speedup of BRT inside KCR shows that the number of passengers decreases by 2%. On the other hand, it is concluded that the KCR demand will not be influenced evidently by the speed-up of BRT inside the KCR in the case N-B1,B2.

3.6 KCR Demand with Alternative Fare Level

The fare level of KCR in demand forecasting of the foregoing paragraph is set up so that a user may be easily alike and it can convert into KCR from a bus in consideration of the fare level of the existing bus.

The amount of time crunches by KCR use is so large that distance is long. Therefore, the slope of the example charge of a distance ratio can count upon use of KCR also by a steep slope as compared with the one of a bus. Then, the fare level which can acquire a higher profit was studied as there was no burden in short distance use.

Moreover, although the speed of the bus at the time of demand forecasting of the foregoing paragraph used 15 km/h (the results of the investigation in 2011 by KTIP), the average speed of the bus route which competes with KCR was 12 km/h (the results of the investigation in 2012 by Study Team). Then, about the study here, speed of bus was carried out on condition of 12 km/h.

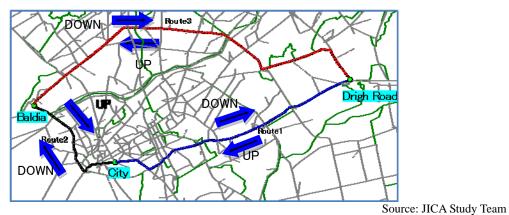

Figure 3.6.1 Mini Bus Travel Time Survey

The studied fare structure is as being shown in Figure 3.6.2, in the case of 10 km which is the average trip length at the time of demand forecasting, the charge of KCR comes from 19 PRs. to 24 PRs.

JICA 3-20 NK-YEC-JEC

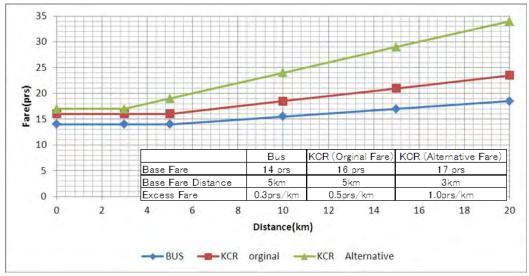

Figure 3.6.2 Fare Level

The demand-forecasting result by two fare structure is as in Table 3.6.1, and although the number of passenger and the maximum number of passengers loaded are almost the same, the fare receipts of alternatives are 1.27 times.

Table 3.6.1 KCR Demand (Case N-B1)

Fare Structure Case	Original	Alternative				
Base Fare	$16~\mathrm{PRs}$	17 PRs				
Base Fare Distance	5 km	3 km				
Excess Fare	0.5 PRs/km	1.0 PRs/km				
Number of Passenger	306,236 pers./day (1.00)	300,309 pers./day (0.98)				
Max. Number of Passengers loaded	225,101 pers./section (1.00)	218,140 pers./section (0.97)				
Fare receipts	5,740282 PRs/day (1.00)	7,284,509 PRs/day (1.27)				
Average Trip Length	10.3 km	10.2 km				
Bus Speed	15 km/h	12 km/h				

Source: JICA Study Team

Since bus speed and monetary value also change in the future, it is predicted that the preference consciousness of KCR also changes. Therefore, before operation, it is required by conducting preference opinion survey and running speed survey to scrutinize the fare level of KCR.

4. REVIEW OF TECHNICAL STANDARDS AND RAILWAY ALIGNMENT

In SAPROF (II), JICA Study Team has studied two options in terms of operating route as mentioned in Chapter 3. One is "Option N-A1" or "Option N-A2" which has entire circular route and the other is "Option N-B1" or "Option N-B2" where KCR operates between Drigh Road and Shah Abdul Latif via Karachi Cantt. Hereinafter, these options are referred to as "Option N-A" and "Option N-B" respectively as route alignment are examined in this section.

4.1 Technical Standards to be applied to KCR

4.1.1 Basic Policy of Technical Standards to be applied to KCR

Pakistan Government requested Japan Government to provide Yen STEP Loan for the implementation of the KCR Revival Project in December 2008. Japanese technologies are presumed to be adopted for the project with the financing of Yen STEP Loan. Therefore, the technical standards to be applied to KCR should be based on Japanese railway standards, and this was authorized through ECNEC's approval of PC-1 modified May 2009 and confirmed at the wrap-up meeting held on 29 October 2011.

4.1.2 Outline of Technical Standards to be applied to KCR

The Japanese technical standards on railway are compiled under the supervision of Ministry of Land, Infrastructure, Transport and Tourism (Ministry of LITT). The outline of technical standards applied to KCR with track gauge of 1435 mm relating to alignment planning is shown in Table 4.1.1.

4.1.3 Rolling Stock Gauge for KCR

According to Japanese technical standards, the vehicle gauge mostly used in Japan is Option-1 as shown in Figure 4.1.1. Option-1 is set down in a way that the car width may be expanded over the platform height taking into account the gap between vehicle and platform which is mostly used in Japan. This shape of rolling stock is used not only in Japan but also in worldwide. Therefore, Option-1 has an advantage of scale production.

On the other hand Option-2 is planned in a foreign country project and can be introduced in consideration of the design of platform to be newly constructed. The reason of selection of Option-2 is that Option-2 has an advantage of processing cost reduction thanks to omitting bend of car side.

However, the consultation with Japanese reputable manufacturers of rolling stock revealed that total cost of fabrication for Option-2 is not always more economic than Option-1 because Option-2 needs specific templates to form side plates.

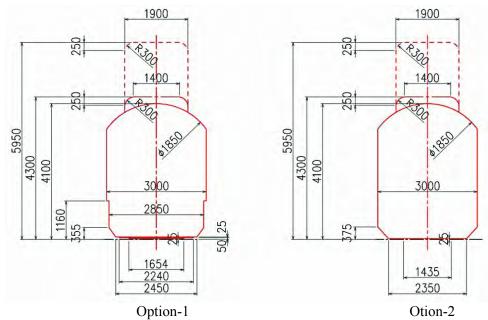

Therefore, Option-1 is recommended that KCR vehicle gauge is 3m in width.

Table 4.1.1 Outline of Technical Standards to be Applied to KCR

		Standards			
Item		Value Unit		Remark	
	Main line	400 (200)	m	Figures in the parenthesis are	
Minimum Curve Radius	Depot	100	m	applicable in inevitable cases due to topographic reasons and so on.	
	Basic Width of Construction Gauge		mm	Assumption of adoption of the proposed rolling stock	
	Equivalent Super-elevation	11.3* V ² /R	mm	Track Gauges Actual Super-elevation of 1435mm	
Cant	Maximum Super-elevation	150	mm	Defending to Coope of Other	
	Maximum Super-elevation Deficiency (C _d)	90	mm	Referring to Cases of Other Railways	
Maximur	n Speed	110	km/h	Shorter Scheduled Time	
Maximum	Gradient	3.5	%	Speed Restriction for Downward=85km/h or less	
	Type of Curve	Cubic Parabo	ola	Easy to setting and maintenance	
Transitional	L_1	300C _m	mm		
Curve Length	L_2	1/1(' V/5 Q(' V) mm		Cm stands for the actual cant set in the curve section concerned	
	L_3	$6.7C_{d}V(5.2C_{d}V)$	mm	in the curve section concerned	
Tumout	Main line	10#		12# in SAPROF(I)	
Turnout	Depot	8# (6# at sub-main	n track)	10# in SAPROF(I)	
Width of Vehicle Gauge		3000	Mm	See Vehicle Gauge	
Width between Track Centers		3700	mm	Assumption of adoption of the proposed rolling stock	
	10/1000 or more	R=2000	m	SAPROF: 3000m. In case of competition of horizontal curve	
Vertical Curve	Less than 10/1000	not required		radius 600m or less, the vertical curve radius is required at 3,000m	
Extra Clearance by Curve (Over-throw and End throw)		24400/R	mm	L ₀ =2,100mm, L ₁ =13,800mm In case of R=200m Over-throw=122mm	
Platform Height from Rail Level		1100	mm	Consideration of Height of Car Floor	
Distance from	Inward Platform	K=W+s+C*h/G		K and K': Extra clearance W: Over-throw, C: Cant	
Track Center to Platform Edge in curved Section	Outward Platform	K'=W-C*h/G		G: Track Gauge, h: Platform height S: Slacking in case of Electric car (negligible small)	
Upper Clearance for Pakistan Railways (PR)		6350	mm	According to PR Technical Standard, the upper clearance for future 25kV AC is 6,325mm.

Figure 4.1.1 Vehicle Gauge of KCR

4.1.4 Construction Gauge for KCR

(1) Width of construction gauge

The maximum car sway is estimated as 20 cm and the vehicle gauge of KCR is 3 m. The protection space for the passengers in trains who poke their arms or heads out of the windows of cars is required as 20 cm. Therefore, generally the construction gauge needs the width of 3.6 m or more (= car gauge 3 m + minimum 60 cm), and is normally adopted at 3.8 m.

Source; New Track Structures: The Japan Railway Civil Engineering Association

Figure 4.1.2 Required Distance between Track Centers

When cars are designed in such a way that passengers cannot poke their arms or heads out of the windows of the trains by limiting opening space of the windows, Japanese standards permit omission of the protection space. In this case the width of construction gauge is reduced to 3.4 m.

JICA Study Team proposed such type of cars as rolling stock of KCR and KUTC agreed. Therefore, the construction gauge of KCR is changed from 3.8 m proposed in SAPROF (I) to 3.4 m as shown in Figure 4.1.3.

JICA 4-3 NK-YEC-JEC

(2) Upper clearance

Upper clearance in construction gauge depends on the Electrification System.

As the traction power of KCR is alternating current (AC) 25 kV x 2 (AT system), Study Team referred to the same system in Japanese case adopted to Tsukuba Express (TX) which was newly constructed as independent urban railway including 20 kV alternative current section based on the Japanese modern railway technologies.

Thus, Study Team determined the upper clearance of KCR shown in Table 4.1.2 based on TX construction gauge.

^{*} Insulation distance of Tukuba Express is 250mm for 20kV and that of KCR is 300mm for 25kV.

4.1.5 Distance between Track Centers

(1) Over Throw and End Throw due to Curvature

A car of trains has a rectangular box body supported by 2 bogies with 2 axles each which have fixed wheels respectively as shown in Figure 4.1.4. When a car runs in a curve section, the center of cars gives an over throw to the center of the curve and the both ends of a car gives an end throw outward of curve. Furthermore, a car in curve section gives a lean due to the super-elevation. Therefore, in curve sections the distance between track centers needs expansion according to the radius of the curve and actual super-elevation.

Source; Japan Railway Contractors Association Seminar Materials 2007

Figure 4.1.4 Railway Car Structure and Throw in Curve Sections

As the over throw W_1 is larger compared with the end throw W_2 , the over throw is used as the representative value W of the two. W is calculated using the following formula.

 $W = W_1 = R - [R^2 - (L_1^2 + L_0^2)/4]^{0.5} \\ \ \, \doteq \ \, (L_0^2 + L_1^2)/8/R = 24,400/R$

Where; R: Curve Radius (m)

 L_1 : Distance between bogies= 13.8m

 L_0 : Rigid wheel base= 2.1m

W: Throw in curve sections (mm)

As the minimum curve radius in the main lines of KCR is 200 m, the maximum throw is computed as 122 mm.

(2) Lean due to Curvature

When a train runs in a curve section, the cars incline due to curvature and need another space to safely run without bumping something as shown in Figure 4.1.5.

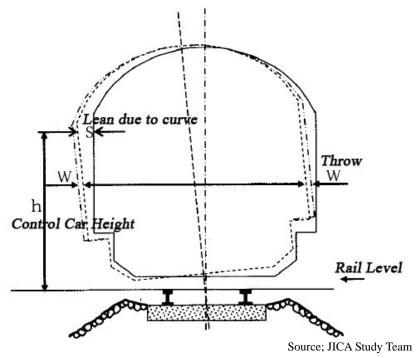

Figure 4.1.5 Lean due to Curvature

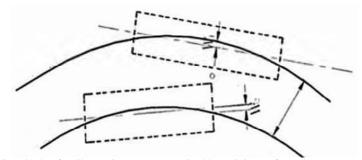

S is calculated using the following formula, where S is lean due to curvature, h is the control height of a car, C is the super elevation (cant) set in a curve and G is the track gauge.

 $S=h \times C/G$

As h is less than 3,500 mm in case of a car to be introduced to KCR, the maximum cant is 150 mm and G is 1,435 mm, the maximum value of S is 366 mm.

(3) Examination of Distance between Track Centers

The minimum necessary distance between track centers is examined on the critical situation when two trains pass each other as shown in Figure 4.1.6.

Source; Civil, Technical Standards of Railways in Japan supervised by Ministry of Land, Transport, Infrastructure and Tourism

Figure 4.1.6 Critical Situation for Examination of Track Centers

In this case the additional required distance between track centers D is calculated using the following formula.

 $D=A+W_1+W_2$

Where: A: Differences of lean due to differences of cants

W₁: Over Throw of one of the lines concerned

W₂: End Throw of another line concerned

As the cants set for Up line and Down line are same, the leans of Up line and Down line are same. As W_1 is larger than W_2 , W_1 is used instead of W_2 for the safety side design. Therefore,

$$D = W_1 + W_1$$

In a curve section, the concentric curves are used as the alignments of Up line and Down line. According to the technical standards applied to KCR shown in Table 4.1.1, the minimum curve radius is 200 m which is used as the radius of the inward curve and the radius of outward curve is about 204 m. As the maximum permissible cant is 150 mm, D is calculated as follows.

As the construction gauge applied to KCR is 3,400 mm, the required minimum distance between track centers is 3400 + 242 = 3642 mm, $\frac{\text{say } 3,700 \text{ mm.}}{\text{say } 3,700 \text{ mm.}}$

(4) Conclusion

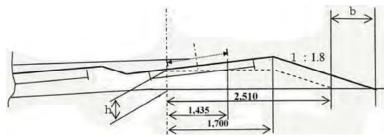

KCR is a circular line and inevitably has many curves. In curve sections the distance between track centers has to be expanded due to over throw and end throw of cars. When the distances between track centers are frequently expanded and reduced, the lands outside ROWs are not good for utilization. Therefore, the distances between track centers are desirable to be constant for KCR.

JICA Study Team proposed KUTC the constant distance between track centers of KCR of 3.7 m for the entire sections regardless of curve or straight alignment and KUTC accepted this proposal. It is concluded that the distance between track centers of KCR is decided at 3.7 m.

4.1.6 Width of Formation

The structures of KCR basically consist of three types, that is; ground sections with ballasted track, viaduct sections with solid-bed track and culvert or U-shape sections with solid-bed track. As explained in the preceding section, the space for train running in curve sections must be expanded. Accordingly, the width of formation also needs to be expanded.

Moreover, in the curve sections of ballasted track, the space for stability of increased height of ballast as shown in Figure 4.1.7 is required.

Source; Civil, Technical Standards of Railways in Japan supervised by Ministry of Land, Transport, Infrastructure and Tourism

Figure 4.1.7 Expansion of Formation due to Cant Increase in Outer Parts in Ballasted Section

Taking into account over throw & end throw, lean and space for protection of ballast due to cant, the proposed formation width with no need for expansion regardless of curve in ballasted track sections is shown in Table 4.1.3.

Table 4.1.3 Proposed Formation Width in Ballasted Sections

Item of Breakdown	Width required by technical matters (m)	Width required by ballasted structure (m)	Remark
Width of construction gauge	3.4	3.4	3.4m /2 x2 lines
Distance between track centers	3.7	3.7	
Over throw	0.244	0.244	0.122m x2 lines
Lean of car	0.704	0.704	0.352m x2 lines
Allowance	0.7		0.35m x2 lines
Space of maintenance pathway	1.4	1.4	0.7m x2 lines
Basic width of ballast	-	5.02	2.51m x2 lines
Total	10.148	11.038	
Proposed width of formation for ballasted section including reinforced embankment		11.1	No need of expansion of formation due to curvature
Space for electric pole	1.5	1.5	0.75m for each side
Proposed width at pole section		12.6	No need of expansion of formation due to curvature

The formation width without need for expansion in viaduct sections and culvert or U-shape sections was proposed as shown in Table 4.1.4 as well.

 Table 4.1.4
 Proposed Formation Width in Viaduct and Culvert or U-shape Sections

-		-
Item of Breakdown	Required Width (m)	Remark
Basic width of construction gauge	3.4	3.4m /2 x2 lines
Distance between track centers	3.7	
Over throw	0.244	0.122m x2 lines
Lean of car	0.704	0.352m x2 lines
Space of maintenance pathway	1.4	0.7m x2 lines
Width of wall	0.4	0.2m x2 lines
Allowance for both sides	0.7	0.35m for each side
Total	10.548	
Proposed width of viaduct or reinforced embankment	10.6	No need of expansion regardless to curve section or not
Space for electric pole	1.5	0.75m for each side
Proposed width of viaduct or reinforced embankment width at pole section	12.1	No need of expansion regardless to curve section or not

KUTC agreed with all the formation widths proposed by the JICA Study Team and decided as shown in Figure 4.1.8 and Figure 4.1.9.

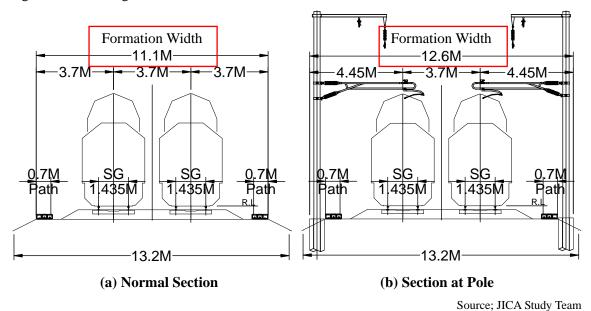

Figure 4.1.8 Formation Width of KCR at Ground Section

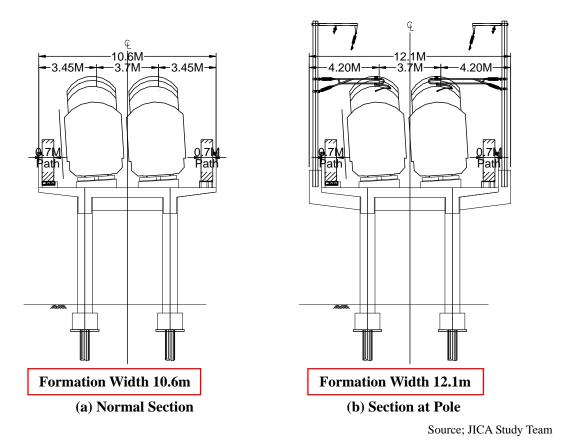

Figure 4.1.9 Formation Width of KCR at Viaduct Section

4.2 Basic Policy of Station Design

This section gives the comprehensive station plan including type of station, platform design and intermodal facility.

4.2.1 Type of Station

The Karachi Circular Railway (KCR) to be revived is planned based on no level crossing concept so as not to affect the road traffic.

In the sections where many roads densely cross the KCR route, viaduct structures are adopted and therefore viaduct stations are planned. In the sections where existing roads currently cross over the KCR route or existing level crossings can be economically eliminated by ROB or RUB, the on-ground alignment is planned and the on-ground platforms and over-track stations are planned to access easily and safely to both sides of track facility. Furthermore, in the trench section according to the topographic conditions, underground or semi-underground stations are designed.

(1) Viaduct Station in Elevated Sections

In the elevated sections, platform is placed along elevated track on viaducts. Passengers who get off trains go down to ground level where ticket gates are located as shown in Figure 4.2.1. In a viaduct station, the station facilities such as ticket vending machines, staff office and information counter are placed in ground level of viaduct structure.

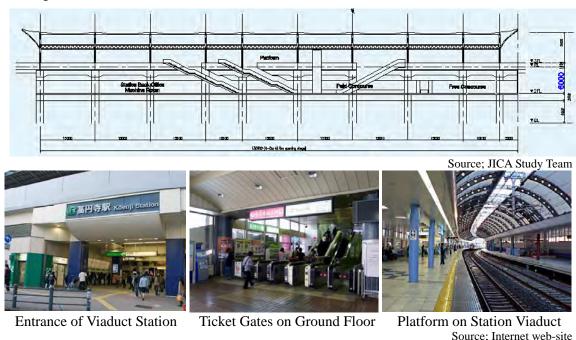

Figure 4.2.1 Example of Viaduct Station

When a viaduct station is planned on a busy road and it is required that passengers should avoid crossing the road for easy and safe access to the other side of the road, the station is planned as three-story structure and the station facilities such as ticket gates and station staff rooms can be designed on the first floor as shown in Figure 4.2.2

Station Area

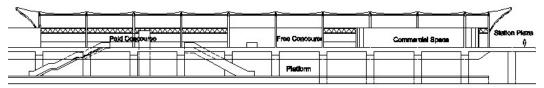

Figure 4.2.2 Example of Three-story Viaduct Station

(2) Over-track Station in On-ground Sections

In on-ground track sections, platforms are also placed on ground level along the track and stations are designed as over-track station to avoid dangerous track crossing by passengers and disturbance against train operations. Passengers who get off trains go up to the first floor where ticket gates are placed. In

the over-track station, station facilities such as ticket gates, ticket vending machines and station staff office are planned on the first floor and passengers easily and safely access to the roads toward both sides of railway track.

An example of the over-track station is shown in Figure 4.2.3.

Source; JICA Study Team

Source; Internet web-site

Figure 4.2.3 Example of Over-track Station

(3) Underground or Semi-underground Station in Trench Section

Along a hilly landform lies in the section from Depot Hill up to Nipa, trench structures are adopted for KCR to reduce the railway gradient for efficient operation and economize the construction cost. The platforms are placed in the trench along the track and station facilities are planned over track by using box culvert structures. Passengers who get off trains go up to ground level where station facilities such as ticket gates and station staff office are located.

Figure 4.2.4 shows the perspective of Johar Station and example of semi-underground station is shown in Figure 4.2.5.

4.2.2 Platform Design

(1) Platform Type

There are two types of platforms, side platform and island platform.

1) Side Platform

A side platform places separate platforms for respective up and down lines outside the tracks as shown in Figure 4.2.6.

Source; Internet web-site

Figure 4.2.6 Side Platform

Side platforms have the following features:

- A) The good track alignment near platforms can be maintained.
- B) Future improvement such as expansion of platform length is easier and less expensive than island platforms.
- C) When passing tracks are installed in the center between both normal tracks, passengers on platforms can avoid risks by passing trains.
- D) However, side platforms require wider ROW in station sections.

2) Island Platform

An island platform places single platform between up and down lines as shown in Figure 4.2.7.

Island platforms have the following features:

- A) They can economize station space and can be installed in narrower width of ROW.
- B) In the case that two different lines meet at a station, island platforms enable such arrangement that passengers can transfer from one line to the other line at the same platform.
- C) For a station where shuttle operation is planned, island platform is convenient for passengers because single platform is used for both getting off and getting on.
- D) However, an island platform with insufficient width against passenger volume will endanger passengers on platforms, may cause suspension of ticket gate operations for getting-on passengers, and furthermore, may disturb train operations.
- E) Platform improvement after opening of a line is very difficult and more expensive.

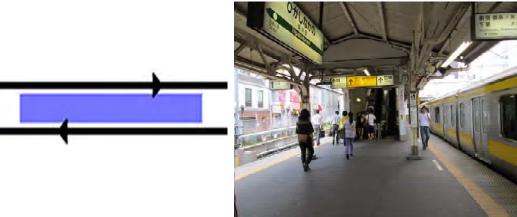

Figure 4.2.7 Island Platform

JICA Study Team examined appropriate platform types from the viewpoint of available land and train operations such as pendulum operation. The results of application of platform types to KCR stations are as shown in Table 4.2.3.

(2) Platform Width

The width of platform is very important for safe and on-time train operations, and is closely concerned with the required land for the station. However, since no precise topographic map was available at the stage of SAPROF-I Study, the platform widths of KCR stations were not discussed at that time.

This SAPROF-II Study includes elaboration of a 1/2000 topographic map with a required accuracy for the entire route and 1/1000 maps of the premise of all KCR stations and the review of route alignment of KCR was conducted using these maps.

Before conducting a review of KCR alignments, the technical standards for adequate width of platform to be applied to KCR stations are needed to be examined and decided.

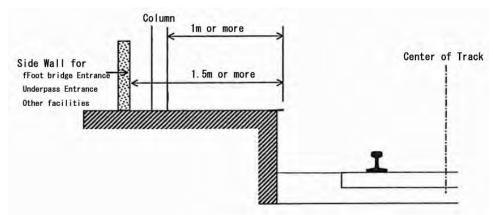

Escalators and/or elevators are generally installed on platforms in a modern urban railway. Moreover, safety clearance between the walls of staircases or escalators and platform edges is required for passengers so as to avoid contact with trains or falling into track. The required width for accommodating such facilities and ensuring safety clearance is generally wider than width required for passengers' flow on platforms.

Also, the stations of KCR are required to be arranged within the given land in accordance with the former KCR's ROW and RAP.

Although width of platforms of a commuter railway to be newly constructed in Japan is 10 m in general, that for KCR stations was at first examined on the required width for staircases, escalators and safety clearance between walls and platform edge (called as 'physically required width') and then the physically required width will be checked from the viewpoint of proper passenger flow capacity.

1) Physically Required Width of Platforms

To secure safety for passengers on platforms against trains, it is necessary to consider the safety clearance against various facilities on a platform such as columns, staircase entrance, escalators and elevators. These minimum safety distances are provided as shown in Figure 4.2.8 according to Japanese Railway Technical Standards.

Source; Japanese Technical Standards for Railways supervised by Land, Infrastructure, Transport and Tourism

Figure 4.2.8 Minimum Safety Clearance from Edge of Platform

However, taking into account two Pakistan passengers who aren't accustomed to train operations with high frequency, JICA Study Team decided to recommend KUTC to expand the clearance between platform edge and obstacle such as staircase wall from 1.5m to 1.8m.

Therefore, the minimum widths of platforms are required to be '1.8m + width of staircase' for side platforms and '2 x 1.8m + width of staircase' for island platforms respectively.

<u>As to width of staircase</u>, escalators for 2 persons are planned for both up and down directions whose capacity of an escalator for 2 persons is **6750 persons/hour**. The dimension of a standard escalator for 2 persons is 1004 mm for width of step, 1200 mm between balustrades and 1600 mm up to 9.5 m height and 1700 mm above 9.5 m height respectively for width required for installing. Therefore, in case where two escalators for both up and down are placed in a staircase, width of staircase is 2 x 1700 + stair step width + 2 x 200 (width of stair wall) = **3800mm + stair step width is required**.

The passengers flow speed in a stair is estimated to be about 1.3 persons/m/sec. The width required for one person moving and an allowance for passengers not to touch passengers coming from the opposite direction are 0.7 m and 0.1 m respectively in Pakistan taking into consideration average Pakistani build and has a capacity of 3276 passengers/0.7m/hour for up or down. An allowance for moving passengers not to touch the staircase wall is 0.1 m. Considering the above-mentioned matters, the minimum width of stair is 0.7 m x 2+ 0.1 m \times 3 = 1.7 m. Therefore, the total minimum width of a staircase with two escalators is 3.8 m + 1.7 m = 5.5 m.

Consequently, the minimum width of platform is 5.5 m + 1.8 m = 7.3 m for a side platform and 5.5 m + 2 x 1.8 m = 9.1 m for an island platform respectively.

In case that there is not enough land in a station section, such a way that a staircase and escalators are separately placed is recommended. With this method, the minimum width of platform is decided by width required for escalators space. It needs 1.6 m + 3.8 m = 5.6 m, say 6m for a side platform and $1.8 \text{ m} \times 2 + 3.8 \text{ m} = 7.4 \text{ m} \approx 7.5 \text{ m}$ for an island platform. In addition, in this case the passenger flow capacity also becomes larger because the width of the staircase can be expanded up to the width for escalators space. Table 4.2.2 shows the relation between width of platform by type and passenger flow capacity based on the above-mentioned matters.

Table 4.2.2 Platform Type, Width of Platform and Total Passenger Inflow/Evacuation Capacity

Platform Type		Side Platform	Island Platform				
Item	Minimum Width (m)	Passenger Flow Capacity (Passengers/h)	Minimum Width (m)	Passenger Flow Capacity (Passengers/h)			
1 Staircase with 2 Escalators	7.3	20,052	9.1	20,052			
1 Staircase with 2 Escalators + One simple Staircase	7.3	33,156	9.1	33,156			
1 Staircase and 2 separate Escalators	6	20,052	7.5	26,604			
2 Staircase and 2 separate Escalators	6	26,604	7.5	39,708			

Source; JICA Study Team

Based on Table 4.2.2, JICA Study Team recommends staircase and escalators separate type taking into consideration the situations of available land for KCR. Consequently, tentative platform plan of KCR stations are proposed as shown in Table 4.2.3.

2) Examination from the Viewpoint of Passenger Flow Capacity

Based on the results of 2051demand of N-A1 case (Case whose demand is supposed maximum), the platforms of KCR Station Plan was examined as follows;

A) Platform width required for forecast passenger volume 2051 of N-A1 Case

The following is a Japanese formula to calculate an adequate platform width for urban railways. This formula was developed based on collection and analysis of broad data of factual investigations on almost all urban stations in Tokyo of former Japanese National Railways (JNR).

 $W=W_1+W_2+\gamma$

W; Required width of a platform for urban railways

W₁; Width occupied by passengers crowded in front of a vehicle door to get on a train during peak hours

In the case of multiple unit trains,

 $W1=0.2 \text{ x } (Pa/N)^{0.5}$

Pa; Average boarding passengers of a train during 30 minutes of peak hours

N; Number of cars of a train formation, <u>N=8 supposed in 2051 of N-A1 case</u>

W₂; Width for alighting passengers to move on a platform

In the case of multiple unit trains,

If $P_b/N \le 6.4 \text{ x LN}$, $W2=2/3 \text{ x } P_b/(LN)$

If $P_b/N > 6.4 \text{ x LN}$, W2=13/3 x N

P_b; Average alighting passengers of a train during 30 minutes of peak hours

L; Length of a car <u>L=20m in case of KCR</u> (also, L=20m in Japan)

 γ ; Allowance caused by columns and distance for taking shelter against running trains

Allowance for taking shelter against running trains; 0.8 m

Allowance for a column; 0.3 m

Allowance for benches:

Side home not facing a station building 1.1-1.4 m

Side home facing a station building 2 m

KCR adopts over-track station type or viaduct station type and there is no platform facing station buildings. Therefore;

 $\gamma = 0.3 + 1.4 = 1.7$ m for a side platform

 $\gamma = 0.8 + 0.3 + 1.4 = 2.5$ m for an island platform

Table 4.2.4 shows the forecast demand in 2051 (30 years after commencement of operation) for calculating the required widths of platforms of KCR stations and Table 4.2.5 shows the required widths calculated using the above-mentioned formula.

Source; JICA Study Team

Normally demand of up line and down line at the station is almost same and the platform width of up line should be same as that of down line. The required widths calculated above are different between up-platform and down-platform due to the nature of demand forecast model. JICA Study Team takes larger values as the proper width of platforms at each KCR stations in Table 4.2.5. According to Table 4.2.5, the revised platform widths of KCR stations are proposed as shown in

Table 4.2.6, where only platform width of Drigh Road is changed from 7.5 m to 7.7 m or more.

Table 4.2.6 Final Platform Types and Width of KCR Stations

B) Passenger Inflow/Evacuation Capacity of Platform by Station

A platform should have a capacity of inflow/evacuation capacity which satisfies the condition that the passengers of preceding train can be evacuated from platform before next train arrives and passengers for next train can inflow into the platform. If such capacity is insufficient, passengers who get off preceding trains and get on next trains pile up and the dangerous big mess can arise and at last may causes suspension of train operations. To avoid such mess passenger, the inflow/evacuation capacity should be larger than the total of peak hour alighting and boarding passengers of the platform. The relation between total forecast alighting and boarding passengers in 2051 and passenger inflow/evacuation capacity by platform by station is as shown in Table 4.2.7.

Table 4.2.7 Relation between Alighting/Boarding Passengers and Passenger Inflow/Evacuation Capacity by Platform at Each Station

	Peak Hour Demand in 2051

Source; JICA Study Teeam

As the result of comparison between total alighting and boarding passengers and platform inflow/evacuation capacity, it is confirmed that capacity of all the KCR stations is sufficient.

4.2.3 Intermodal Facility Plan

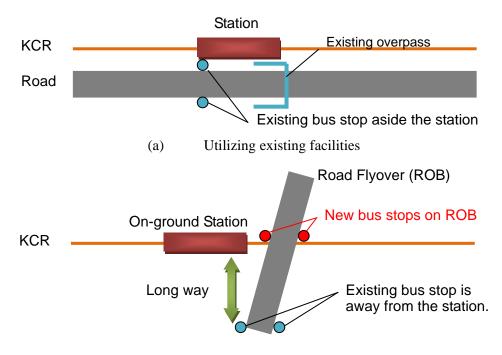

(1) Basic Policy

Actually minibuses and coaches cover public transport in Karachi. When KCR starts to operate, the passengers who go to CBD by minibus or coaches are expected to transfer to KCR at the KCR stations. However, if transfers from road transport to KCR are inconvenient or unsafe, most of bus users do not want to transfer to KCR and as the result, the number of transfers remains a few. Consequently, it is very important to provide good intermodal facilities which can facilitate passengers' willingness to transfer to KCR.

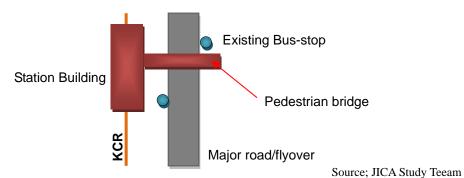

On the other hand, cost reduction is required for the project and limitation of available land to former KCR ROW arranged by RAP is expected.

Taking into account such requirements, JICA Study Team suggests the following policy on intermodal facility plan:

- A) As for station plaza, desirable plaza space at each station is planned as a future plan which is described in Appendix 4-1. However, the provisional station plaza plan to be prepared up to the commencement of the KCR operations will be provided within available land in this study.
- B) Existing pedestrian overpasses or underpasses will be optimized as shown in Figure 4.2.9 (a).
- C) In the case that main road ROB is very near a KCR over-track station, a connecting footbridge and bus stop facility will be provided as shown in Figure 4.2.9 (b). However, the details of the facilities of foot bridges and bus stops will be examined in the basic design study.
- D) In the case that a KCR viaduct station is very near a main road which crosses KCR, an access facility to the road and bus stop facility will be provided.
- E) In the case that an underground/semi-underground station is very near a main road which crosses KCR, a pedestrian underpass and bus stop facility will be provided.
- F) In case of few access routes to existing bus stops from a KCR station, a ground pathway or footbridge will be provided to access from the station to the existing bus stops as shown in Figure 4.2.9 (c), (d).

Figure 4.2.9 Basic Concept of Intermodal Facility

(2) Provisional Station Plaza Plan to be provided up to Opening of KCR

The followings are the provisional station plaza plan based on the results of land survey, utilizing existing cross roads and intermodal facilities such as bus stops.

The summary of intermodal facilities at each station is shown in Table 4.2.8.

Table 4.2.8 Summary of Intermodal Facility at Each Station

	1able 4.2.8	Summary of intermodal Facility at Each Station						
No.	Station Name	Туре	Planning Intermodal Facility except Station Square					
1	Drigh Road	Elevated	Pedestrian overpass and subway					
2	Johar	Trench	Pedestrian deck with bus stop
